Naegle, who has probably given this subject more attention than anyone else, the head lies in the right oblique in 99 per cent. of all cases. Admitting the frequency of the occiput occupying a posterior position, and knowing the dangers which may result before the case has terminated, it has been the author's experience that the head does not engage as easily in this position as in the anterior one. In O. L. A., for instance, the head enters the pelvis with both parietal bones on the same level, that is, the biparietal diameter of the head passes through a pelvic diameter parallel with and about equal to one of the large oblique diameters. In O. R. P. position, however, this does not occur, and the head passes through a much smaller diameter. While it may not be possible to correct every case by posture, the number of successful ones is so large that every case diagnosed as O. D. P. before labor should be treated as follows: Caution the woman to lie upon her right side at night, and at all times when she is lying down. Each night and morning she should assume the knee-chest position for ten minutes. If the head be above the brim, in but very few cases will this treatment fail. In this position the anterior wall will be lower, the fetus rotating on its long axis, and the dorsum, being the heavier, naturally will seek the most dependent part of the uterus. The knee-chest position allows the head to settle away from the brim. In taking this position, the abdomen must be entirely free of tight clothing. Take another case, when the diagnosis has been made after labor has commenced, but the head still above the brim, the same treatment is often beneficial. The object of position in these cases is not only that anterior rotation may be favored, but a more perfect flexion of the head may be maintained. If flexion is not secured, we have the sinciputal end nearly on a level with the occiput; entering the pelvis in this way, labor is delayed, and when the head settles down, the sinciput coming in contact with the pelvic floor rotates forward and the occiput engages in the hollow of the sacrum, or we get a deep transverse in arrest which calls for artificial correction. While we speak of the occiput rotating posteriorly, we probably should say the sinciput rotates anteriorly Hart's law: Whatever position of the fetal body first strikes the resistance of the pelvic floor, whether it encounters this structure behind or in front of the median transverse line is directed forward, inward and downward under the arch of the symphysis. When the occiput is engaging slowly and the lateroprone position has failed, often much good will result by placing the patient in the Walcher position. There is still another class of cases where the head has engaged in the brim, the os dilated, but no progress being made. In this class the treatment to be first attempted is one which will nearly always succeed.

GENERAL.

Russian Medical Naturalists.—On January 2, 1902 (Dec. 20, 1901, ordinary calendar), the opening of the Seventeenth Congress of Russian Naturalists and Physicians will take place at St. Petersburg. The executive committee is formed of the president, M. le Prof. N. A. Menchoutkine, the vice-president, M. le Prof. A. A. Inostranzeff, the secretaries, MM. les Prof. I. I. Borgman and W. T. Chewiakoff. The Congress will be divided into the following sections: Mathematics and Mechanics, Astronomy and Geology, Physics, Geography, Chemistry, Geology and Mineralogy, Botany, Zoology, Anatomy and Physiology, Scientific Medicine and Hygiene. The Congress will be in session until January 12th. Those desiring to take part should communicate with the Executive Committee (St. Petersburg University).

CORRESPONDENCE.

BERLIN LETTER.

[From Our Special Correspondent.]

BERLIN, Oct. 14, 1901.

THE EIGHTIETH ANNIVERSARY OF RUDOLPH VIRCHOW.

"Homo sum, humani nihil a me alienum puto." These words of the Roman poet Terenz are eminently suitable to characterize the life and the principles of Rudolf Virchow. From the very earliest years of his scientific labors and public work, through all his endeavors until the present day, we can follow one distinct thread, the love of truth. Never bending himself to achieve success through byroads, he enlisted his untiring energy to fight for those principles which he had recognized as the right ones and he never rested on his shield, though he had done work a part of which would have made scores of men celebrated. His watchword was and is, "Excelsior."

His teacher, the great biologist Johannes Müller, enlisted him into the little army which fought against the mystic speculation of natural philosophy in medicine. Johannes Müller's school was strictly the school of positivism and nobody was more enthusiastic to follow the path of his teacher than Virchow.

The fruits of his earlier labors are our knowledge of embolism and thrombosis, leucemia and septic infection, but he crowned his work and covered himself with immortal glory, when in 1858 he uttered the little sentence *"Omnis cellula a cellula,"* and with these words laid the foundation of the principles of modern pathology, that branch upon which our entire modern medicine is resting. Men will come and go, empires and kingdoms may appear and disappear, but Rudolf Virchow's name will live forever and his lifework will be the admiration of the coming generation.

To this man equally as eminent as anthropologist, hygienist and statesman, as he is in medical pathology, have come the representatives of the civilized world to celebrate his eightieth birthday.

The celebration was divided into two parts. In the afternoon the inspection of the pathological

museum and an address by Virchow; in the evening the greeting and congratulations of Virchow's friends and admirers in the second chamber of the Prussian diet, a member of which he has been for decades.

At two o'clock the invited guests assembled in the aula of the pathological museum. The meeting was representative and international. England had sent Sir Joseph Lister and Sir Felix Semon; Italy, Professor Baccelli; France, Senator Prof. Cornil; Austria, Prof. Toldt; Russia, Botkin; Holland, Stockvis; Norway, A. Hansen. A tremendous applause greeted the master when he addressed the meeting. After a few well-chosen words of thanks, he spoke as follows: "While the scientific explorer enjoys such success in his work as he may achieve, it is only an impetus to new efforts and he is fully aware that what is to-day accepted as true and a fact, might be overthrown to-morrow." He then went into the history of medicine. "It appears impossible to go back to its beginning, so old it appears to be." A general description of the medical affairs in ancient Greece and Rome, the medieval medical school of Arabia, the Italian universities of Bologna and Padua during the fifteenth century and the entrance of Germany into the field of medical research followed. Two currents existed there; the one, which represented the Arabian doctrines, was led by Paracelsus, the other by Vesalius, the founder of the anatomy of the human body. It is he who might be called the father of pathology. Not death alone, however, but life itself and its changes demand the the attention of the pathologist and pathology belongs to the domain of biology. It would be erroneous to call pathology the teaching of disease. Pathology has no limit and even the field which deals with descendency belongs to its realm. Pathologists at the present time are at work to ascertain the border between formation and metaplasia. Pathological museums collect the proofs of facts found and demonstrated possibilities are of no material value. In olden times superstition and mystical speculation were the helpmates of the anatomist, where his deficient knowledge failed to explain. Especially was this the case in regard to monstrosities. These were considered the work of the devil. It was Meckel who with his embryonic study overthrew this belief. Another field which caused much trouble was the study of parasites living in the human and animal economy. We know now that only life can cause life." At the close Virchow remarked that the new museum should not only serve science alone, but should also be a source of popular instruction.

The next speaker, Surgeon-General Schaper, the director of the Charité Hospital, praised Virchow as the prince of science and a public benefactor. Hereafter demonstration of bacteria and parasites with the projection apparatus and an inspection of the different departments of the museum followed. This closed the afternoon celebration. The evening celebration in the great meeting hall of the Prussian Diet was probably the most imposing ovation which has ever been given to a man of science. The hall was profusely decorated with flowers, and governments and private societies, learned bodies from far and near, universities and cities had sent their representatives to give voice in word and deed to the admiration in which they hold the scientist, the thinker, the patriot and the statesman. At nine o'clock the trumpets announced the arrival of Rudolf Virchow, who was led to the seat of honor by Prof. Waldeyer, who is now on his way to the United States, where he will represent the Berlin University at the two hundredth anniversary of Yale University. He named as honorary presidents of the meeting the following: Minister of Public Instruction Studt; Minister of Agriculture v. Posadowsky; Surgeon-General of the Army v. Leutoldt; Professor Baccelli, Rome; Lord Lister, London; Professor Cornil, Paris; Professor Botkin, Petersburg; Professor Toldt, Vienna; Professor Stockvis, Amsterdam; Professor Hansen, Bergen; Professor v. Recklinghausen, Strassburg; Professor v. Bergmann, Berlin. He then with words of the highest praise, in which he called Virchow the benefactor of the whole world, handed him fifty thousand marks publicly collected for the purpose of the strengthening of the "Virchow Stiftung." Upon him followed the Minister of Public Instruction, who brought a letter from the Emperor and the Gold Medal for Science. Then came the deputies of the Medical Department of State and Ministry of War, the Academy of Science and other learned and scientific bodies to bring addresses and congratulations; and hereafter greeted with great applause the Italian Minister of Agriculture, Professor Baccelli, who delivered a Latin oration, the translation of a portion of which is as follows: "This day, on which in Berlin, the center of science, the highest honors are given to you, Rudolf Virchow, is the day of glory for the world's medical science and the day of happiness for the land of your birth, Germany.

"When your brow is crowned to-day with immortal laurels, this day is the day of justice and for us a day of the purest pleasure. For this reason I was sent to this assembly of illustrious men, who admire you and congratulate you, to tell you what Italy feels for you. First, I speak in the name of our beloved King, Victor Emanuel III., who from a strong and noble ancestry is by his own individuality drawn toward every great virtue, wherever it might appear. Furthermore the Ministers of Instruction and Medicine wished to congratulate you, but, more than anybody else, is Joseph Zanardelli, the successful liberal government leader, anxious to express his joy that you, the beaconlight of science, are unbent by your eighty years and in full manly vigor and strength.

"The science and methods of pathological anatomy, which were first taught in Italy by John Baptist Morgagni, you have, with never equaled wisdom, perfected in your German Fatherland and carried to such height that rightly you may

be called Teacher of Teachers. This the Italians desired to express in this picture and I have inscribed it with the following hexameter: *'Ut gnos corda fovent praesentes lumina spectent.'*

"Hail to you, Rudolf Virchow! May you reach Nestor's age, healthy and happy, an ornament of your country, protector of the human race, admired by all nations, but beloved of Italy, you the Immortal!"

Here Bacelli handed Virchow a most artistically-executed medal and a painting upon which Morgagni and Virchow are represented side by side.

It would take more space than you will allow me to mention all the deputations which followed with their congratulations and I may only be permitted to repeat what the French pathologist, Prof. Cornil, said:

"Dearest Master: Forever you have proclaimed in your work the principles of liberalism, based upon science, the foundation of all progress. You have inaugurated a new pathology, based upon the study of cellular lesions. You are the counselor of the cities in their desire for better hygiene. On account of all this, your friends from Paris bow down before you in loving veneration and wish you a long continuation of your admirable career."

It was long after midnight and long after the proposed time when the celebration ended, and everybody admired the splendid strength and activity of the great man. O. WATERMAN, M.D.

SOCIETY PROCEEDINGS.

NEW YORK STATE MEDICAL ASSOCIATION.

Eighteenth Annual Meeting, Held at the New York Academy of Medicine, October 21, 22, 23 and 24, 1901.

SECOND DAY—OCTOBER 22, 1901.

(Continued from Page 680.)

Malignant Disease of Nose.—Dr. Joseph D. S. Gibb of Philadelphia said that primary carcinoma of the nasal passages is rare. Primary sarcomata of nasal structures is not, however, so rare. As a rule these malignant tumors remain unidentified until it is too late to think seriously of radical operation. Their early diagnosis is an important desideratum. One of the very early symptoms is frequent epistaxis. In nearly every case this symptom was present a considerable time before other symptoms developed. In young persons in whom without special reasons there develops a tendency to bleeding from the nose, careful examination of the nasal chambers should be made, and if unusual conditions of bulging beneath the mucous membrane are found, suspicion should be aroused. When sarcoma of the nose runs into the ethmoid cells hideous deformity is apt to result. It is in these cases especially that the so-called "frog face" is seen. After the growth overruns the ethmoid cells it may find its way into the orbit and force the eyeballs outward. In these hopeless cases of nasal sarcoma the use of Coley's fluid would seem to be especially indicated. It has been employed in two cases, in one of which after two operations there was recurrence of the growth. In this case cure followed, but it was not attributed to the mixed toxins, but to the last operation. In the other case no effect was produced by Coley's fluid.

Distribution of Sarcomata.—These tumors occur by preference in the nasal chambers of males. Out of 96 reported cases 57 were in male subjects. Sarcomata used to be considered especially liable to occur in the young. Recent statistics show, however, that quite as many cases occur after forty as before forty. The absolute diagnosis can only be made with a microscipe after the removal of a whole or part of the tumor. Partial removal of the tumor is condemned by many surgeons, because it is liable to irritate the malignant elements of the tumor into increased activity. Microscopic diagnosis is not easy and not always assured. In certain cases where the pathology has pronounced the fatal word malignancy, the course of the case has subsequently proved the tumor to be of some other variety. At times, unfortunately, when the microscope has seemingly furnished evidence of non-malignancy, a fatal issue has occurred.

Cancer of Large Intestine.—Dr. James Tuttle of New York said that cancer of the intestine, as of all other parts of the body, used to be said to occur mainly in old people. In recent years, however, there have been reports of an increasing number of cases in the young. In New York the Board of Health reports show in recent years 17 cases of intestinal cancer in children under five years of age, 21 under ten years of age, and altogether nearly 200 in people under thirty-five years of age, which was formerly supposed to be almost the lower limit of age for cancer. Dr. Tuttle considers that it is the age of the tissues and not of the individual that lends itself to malignancy. In cases where precocious senility of any tissues develop there is liable to be malignant degeneration.

Types of Intestinal Cancer.—Epitheliomata of the intestine are not apt to produce constipation, especially not early in the case, and do not, as a rule, give rise to blood or pus in the stools. The main symptom is a nagging dyspepsia with intermittent tendencies to diarrhea and the development of cancer cachexia. Such cancers are apt to be insidious in their development and may produce extensive invasion before there is enough discomfort to lead to their discovery. Scirrhus cancer of the intestine is apt to produce stenosis of the lumen of the intestine and obstinate constipation. It is not long, under these circumstances, before there is ulceration and breaking down of tissue. Such cancers are apt to produce a febrile course. The temperature is not, however, due to the cancer itself, although this is sometimes said to be the case, but is due to the failure of movement on the part of the feces, with consequent absorption of fecal material and other toxic agents. Dr. Tuttle has verified this in the rectum, thereby keeping such cancers abso-

lutely clean. The existence of temperature has been prevented.

Operations for Intestinal Cancer.—Operations for cancer may involve the removal of the affected part or are done simply to alleviate symptoms. Artificial anus, for instance, is often made and often gives great relief to symptoms. The statistics of the operation show a large fatality. But this is because the operation is not one of choice, but of necessity, and is done as a rule only when the patient is in very bad condition.

Malignant Disease of the Penis.—Dr. Henry H. Morton of Brooklyn said that carcinomata of the penis originate usually in abrasions of an overlong foreskin. Circumcised Jews are said to be almost free from the disease. People who exercise care in washing the foreskin so as to leave no irritant beneath it are very seldom affected by cancer of the penis. The affection occurs especially in the lower walks of life, in which precautions of cleanliness are neglected. All erosions of the foreskin that are obstinate to treatment should be regarded with suspicion. If the edge is hard and there is hardness beneath the lesions, it is almost surely cancer. Gumma may be mistaken for cancer. Here the therapeutic test should be employed. Death usually takes place in two years if the tumor is not removed. Caustics only excite the tumors to greater activity and do harm. If the tumor is large the whole penis should be removed.

Ethyl Bromide and Ethyl Chloride.—Dr. S. Ormond Goldan of New York read a paper on these substances as surgical anesthetics and described and exhibited apparatus for their administration. He considered that they are more dangerous than ether or chloroform and are suitable, as a rule, only for minor operations. They do very well in taking the place of nitrous oxide at the beginning of anesthesia. Dr. Goldan considers that ethyl bromide is safer and more economical than ethyl chloride.

Ethyl Chloride as an Anesthetic.—Dr. James P. Tuttle of New York gave some details of his experience with 230 cases of anesthesia by means of ethyl chloride. He does not consider it in any sense of the word a dangerous anesthetic. It certainly is not, as Dr. Goldan said, more dangerous than ethyl bromide. Two surgeons in New York have communicated to him the details of two deaths that have taken place from the use of ethyl bromide. In other cases there have been serious annoying symptoms. There have been over 2,000 cases in which ethyl chloride has been employed. Not only have there been no deaths, but there have not even been any dangerous symptoms. If the anesthetic is used carefully it is an ideal method of producing narcosis for minor operations.

Apparatus for Anesthetics.—Dr. Tuttle does not approve of any of the new-fangled apparatus for the administration of anesthetics. The recently-introduced French apparatus have valves that are constantly rusting or buckling, or getting out of order in some way that makes them a nuisance just in the midst of the operation. He uses the old-fashioned inhaler and for short operations now uses in most cases ethyl chloride. This agent does not produce as much relaxation of the muscles as chloroform or ether, but is quite sufficient for such purposes as stretching sphincters or opening abscesses.

Inconveniences.—It is quite as frequent to have nausea after ethyl chloride as after nitrous oxide. Neither anesthetic must be employed with the idea that after vomiting will surely be prevented. The principal advantage of the use of ethyl chloride is the rapidity with which patients come under its influence. Fifteen or seventeen minutes are not required for its administration, but only five to seven minutes.

Advantages.—Besides the distinct benefit of a shorter preliminary stage ethyl chloride can be administered much more easily than nitrous oxide, because the apparatus required is not as cumbersome as that for nitrous oxide. It can be used in conjunction with ether and chloroform, and it is Dr. Tuttle's experience in this matter that has shown the profession how helpful it may be as a preliminary anesthetic.

Perforation of Gastric Ulcer.—Dr. U. W. Hotchkiss of New York reported a case of perforation of gastric ulcer successfully operated upon sixty hours after the perforation had taken place. The patient was a domestic, about thirty years of age, and for some six weeks before the development of acute symptoms complained of flatulence and general dyspeptic symptoms. A painful condition developed that affected most of the abdomen, but was relieved promptly by a cathartic. Afterward there were return attacks of rather severe pain in the left abdominal region. Two nights before her admission to the hospital she had gone to bed feeling perfectly well and was awakened from sound sleep by an intense pain localized mainly in the upper abdominal region. There had been a movement of the bowel on the day before the occurrence of the pain. But for some time before that constipation had been the rule. The painful condition became more diffuse and was accompanied by collapse. As her symptoms continued to increase despite ordinary remedies she was removed to the hospital. When admitted her abdomen was found to be generally tender, to be swollen and the muscles tense and rigid. Her temperature was 103° F., her pulse 132. Distinct symptoms of collapse were present. As constipation seemed to be a principal element in the case she was given a hot enema containing some ox-gall and glycerin. Improvement set in almost at once. The patient was so much better that the attending physicians were sure that mechanical delay of the feces was the principal element in the case. After about three hours, however, her painful symptoms came on again and she was given another enema. This was followed some time afterward by a natural movement that gave great relief. Relief was, however, only temporary and, as the pain returned and with it signs of collapse, the suspicion was aroused of the per-

foration of a gastric ulcer and an exploratory incision was made.

Operation.—The opening of the peritoneum was followed by the escape of gas and by some yellowish sero-purulent fluid. There was intense congestion of the serous covering of the stomach and here and there in the peritoneum flecks of fibrin occurred. The perforation was found in the anterior wall of the stomach and pockets of exudative peritoneal fluid were found scattered through the peritoneal cavity, behind the liver and spleen and along the intestine. Around the opening in the stomach the thickened edges showed that the ulcer had existed for a long time and as there was considerable necrotic tissue around it, it was thought better not to do a resection nor to attempt to bring the edges of the ulcer together, but to turn in the wall of the stomach and secure serous surfaces together by a double row of Lembert sutures. The general peritoneal cavity was then washed out with hot saline solution until the fluid came away perfectly clear. A liter of the solution was left in the abdomen when the abdominal incision was closed. Three days after the operation the patient developed a swelling of the parotid gland. This proved to be an attack of ordinary mumps. The children of the family in which she had been employed had had them before her entrance into the hospital. Otherwise there was no incident in her recovery. She was fed entirely by the rectum for a week and recovered after five weeks. Since then she has had no dyspeptic symptoms nor any discomfort of gastric origin.

Diagnostic Data.—The principal diagnostic data in these cases are the pain and the tendency to collapse after symptoms of an ulcer of the stomach have been present. When gastric ulcer is latent, as so often happens, then when suspicious symptoms occur, the only thing to do is to make an exploratory incision, and this is the best diagnostic method at our command. Ulcer of the stomach occurs more frequently in males, and especially in those over forty years of age. Ulcers are more frequent on the posterior wall of the stomach, but perforation occurs more frequently on the anterior wall. The statistics of ulcer of the stomach are not, however, quite complete as yet. The last collection of cases reported shows that more ulcers occur on the anterior wall.

Medical Abuse of Alcohol.—Dr. Frank Wellington Dennis of Unionville called attention to the fact that doctors not infrequently abuse alcohol as a remedial agent. Alcohol is really an excrementitious product formed while yeast grows in a sugar solution. It is a result of retrograde change and is capable of poisoning the yeast that it produces if in strong enough solution. It is undoubtedly harmful to healthy human beings and a drug that is destructive in health can not be reconstructive in disease. People who do not use alcohol have, at the age of twenty, ten years more expectation of life than those who use it freely. Insurance societies composed of total abstainers have to pay a much lower rate of assessment than others. The routine practice of medical men in this matter of advising the use of alcohol is a mistake that should be eradicated in this twentieth century.

Pelvic Inflammation.—Dr. Abraham Brothers of New York said that the old idea of pelvic inflammation seemed to be best conveyed by the description of an old gynecologist, who said that it was as if plaster of Paris had been allowed to set. Pelvic inflammation should not be considered as a separate entirety, but should always be traced to its cause. It is the treatment of the cause that is important. It comes either from the uterus through the tube, or by continuity of tissue, or through the lymphatics. There is always some single focus of origin to which all the inflammatory conditions can be traced. Usually this is an endometritis, purulent salpingitis or an appendicitis.

Frequency.—More than one-half of child-bearing women carefully examined at autopsy proved to have some pelvic inflammation. For this there are two main causes, puerperal and gonorrheal infection. Usually there is pain on the affected side, from which the inflammatory condition in the pelvis is derived. Sometimes, however, the pain is referred to the other side. Extensive changes may occur in the pelvis without the development of symptoms. When exudates persist for a long time they nearly always contain pus. Sometimes they remain quiescent for very long periods. In one case nineteen years of quiescence was reported.

Treatment.—The line of demarcation in treatment is between cases with and without pus. Where pus exists surgical treatment is absolutely necessary. For parametric conditions, not suspected to contain pus, ordinary local treatment is often of very great service. In the hands of careful conservative observers, non-purulent inflammatory conditions can be made to disappear by the use of douches, local applications and care of the bowels.

Special Skin Diseases.—Dr. Grover W. Wende of Buffalo exhibited a series of skin diseases with lantern illustrations. He brought out the change that has taken place in cases of impetigo contagiosa in the last few years. From simple blebs with tendencies to crust formation, the lesions have now become ring-shaped in character without much crusting. Other cases of interest were pompholyx, dermatitis herpetiformis pustolosa and X-ray dermatitis. In a case of X-ray affection all the skin of the hand of an operator, including even the nails, was completely destroyed. In another case an ulcer of the foot had lasted for two years and a half and the intense pain shows that there is also some involvement of the periosteum of the bone.

Third Day—October 23, 1901.

Symposium on Arteriosclerosis.

Etiology.—Dr. Charles E. Nammack of New York said that the causes of arteriosclerosis are, in addition to the acute infectious diseases, cer-

tain chronic intoxications such as are produced by chronic gout, lead or other metallic poisoning, alcohol or syphilis. The direct cause of the degenerations in the arterial system is due to the narrowing of the small vessels, which throws more work upon the heart and then this reacts upon the arteries. The initial period of the disease is always a contraction of the peripheral circulation. Without this, arterial degeneration does not develop. Over-feeding is a frequent cause of arteriosclerosis, yet geese may be fattened in order to provide livers for the gourmand and pigs may be fattened for market without the production of arterial degeneration.

Psychic Elements.—Though labor delighted in may physic pain, it is mainly overwork that leads to precocious degeneration of arteries; worrying over work is especially serious in this matter, for worry, not work, kills. Physicians are especially prone to suffer from it, though the public does not give them credit with worrying much over their patients. The death-rate of doctors in New York City is only surpassed by that of three classes of people—saloon-keepers, whose occupation is fatal; butchers, who are gluttons, and quarrymen and factory operatives, in whom the dangers of their occupation and poor living make the mortality-rate high. Doctors die particularly from three diseases connected with degeneration of the arteries—Bright's disease, apoplexy and heart-disease.

Symptomatology.—The history of a case of arteriosclerosis does not begin a few weeks before the patient comes to the doctor, but often from the very cradle. Extensive degeneration of arteries may exist without symptoms, though the inevitable breakdown is always preparing. Among the earliest symptoms that brings his condition to the attention of the patient are distress in the region of the heart and pain in the left arm. There often develops a disinclination to work, especially at the occupation which has perhaps been the delight of earlier years. Headaches are easily brought on as the result of indulgence in tobacco and coffee. When these symptoms develop the city doctor must sell his horse and get out into the air and take more exercise. He must deny himself his glass of wine at dinner and take a longer summer vacation, where he will not permit himself to be tempted into doing any of the work of the local practitioner. Outdoor air is better than iodides to widen the arteries, and this is the important prophylactic against the terminal stages of the disease. Herbert Spencer has defined life as a continuous adjustment of internal relations to external relations. This, the patient who finds himself in the early stages of arteriosclerosis must learn to do.

The Heart in Arteriosclerosis.—Dr. Delancey Rochester of Buffalo said that the degeneration of the arteries obstructs the outflow of blood from the heart because of the loss of elasticity. And yet the work thus thrown upon the heart soon causes failure of the nutrition of myocardium. Bouchard has shown that degeneration fragmentation and even atrophy of the cardiac muscle fibers take place. The valves also become affected, first the aortic and then the mitral. Then the development of arteriosclerosis in the coronary arteries leads to angina pectoris. Dr. Rochester detailed certain cases of arteriosclerosis in some of which attention was called particularly to the fact that the most common symptom was epigastric pain. This leads to the diagnosis of gastritis when the real condition was circulatory degeneration.

Treatment.—In Dr. Rochester's experience digitalis is always a dangerous drug in arteriosclerosis, and he finds cactus and valerian much more useful without the attendant risk. When digitalis has to be used he prefers Merck's digitalin. Morphine may have to be employed in cases where pain becomes the most prominent symptom. In one case, where the pain of angina pectoris continued for a long period, ether had to be employed. The main indication is to treat the patient's general condition. The diet must be carefully regulated, all sources of worry must be removed, gentle exercise must be insisted upon and where a heart compensation has failed the patient must be put to bed. In these cases the use of resisted movement, as employed by Schott at Nauheim, is of very great importance. This adds to the muscle tone and soon relieves the condition. Better than digitalis or any other of the supposed heart stimulants is nux vomica. If it is desired to produce the same effect by hypodermic medication strychnine should be employed.

Management of Arteriosclerosis.—Dr. Egbert LeFevre of New York said that the frequent diagnosis of heart failure in recent years shows that the medical profession has come to recognize the existence of a serious condition of lack of power in the circulatory system for which no single adequate pathological lesion can be found. The question of how to prevent its occurrence is one of the most important of present-day medicine. The conditions that develop with degeneration of arteries, the sclerosis of the kidneys and the enlargement of the heart, are evidently all to be classed together. The most important factor in their development is age. Not that advancing years inevitably bring on arteriosclerosis, or that the degeneration of arteries always correspond to the age. Men of seventy may possess better arteries than others of forty.

Etiology.—Undoubtedly the most important factor in the production of the disease is the hereditary predisposition to early degeneration of arteries. There are families in whom cardiovascular symptoms develop comparatively early in life. On the basis of predisposition there are certain elements that are especially active in causing arteriosclerosis. Chronic poisonings, such as are due to lead or alcohol, the intoxication of indigestion, or such diseases as gout and syphilis, are undoubtedly active in this matter. The mechanism of their action would seem to be the production of peripheral spasms in the blood-vessels

with consequent increase of the work for the heart and the larger vessels. Gradually this peripheral spasm lasts longer and forcible heart action with discomfort to the patient, especially after meals, or the systolic movement of the heart may be felt in the head. The first effect of toxemia is an hypertrophy of the muscular coat of the arteries. Toxemias are more apt to develop and to become exaggerated after middle life. A man of forty-five and over is more sedentary in his habits, the function of many organs is disturbed and the lack of exercise causes the failure of excretion of irritating substances. In these cases the underlying tendency to early degeneration of arteries is as important as the tendency in certain families to the development of tuberculosis.

Special Treatment.—It is especially important that persons suffering with beginning arteriosclerosis should not be without occupation. If the condition known as lithemia, or masked gout, develops and the patient is leading a very active life he may have to change his occupation. In a word, the keynote of success in the management of arteriosclerosis cases in their primary stage is specific control of the amount of exercise to be taken and absolute regulation of the diet. Overalimentation is the rule among older people of sedentary occupation and, together with a more luxurious diet, there comes the craving for richer food with consequent dyspepsia. For the depression incident to indigestion stimulants are taken and so a vicious circle of deleterious influences is formed. If the patients have distinct heart symptoms they are usually ready to listen to the advice of a physician. But at times the storm signal of cardiac disturbances does not come and patients are very hard to manage. If the patient has been accustomed to alcohol for a good while and a certain amount of stimulation seems necessary, then he should be limited to the use of whisky. While the amount of food taken must be limited, limitation must not go to such a degree as to cause impairment of nutrition. Loss of weight is a bad sign. Instead of limiting the diet too much there should be an increase of excretion by the emunctories. For this blue pill and salines should be taken symptomatically.

Drug-treatment.—Grey powder and quinine, of each three grains, should be taken at intervals of three weeks to a month. Between times the bowels should be kept open by means of Carlsbad salts or sodium phosphate. The drug-treatment of the early stage of the disease is not as important, however, as that of later stages, the main purpose being to slow the degenerative process.

Management of the Second Stage.—This stage of arteriosclerosis is the consequence of marked obstruction in the arterial system, with consequent cardiac hypertrophy. The patient is apt to feel the thumping of his enlarged heart. The first lesson is to keep up the heart compensation, for, if the circulation fails, a vicious circle is formed and the condition is rendered inveterate. All violent exercise should be avoided because of the call it makes upon the circulatory system. There should be a simple nutritious diet and no overloading of the stomach. Acute dyspeptic attacks are not infrequent and are best relieved by purgatives. For the feelings of discomfort that develop in the precordial region the nitrites gives transient relief and nitroglycerin for a little longer. After the nitrites there is always a reactionary increase of tension in the peripheral blood-vessels and so the use of these remedies should not be continued over long periods. Iodine and its salts are said to be the drug of arteries. It lowers blood-pressure without decreasing the force of the heart. Five to fifteen grains of an iodide three times a day renders blood-pressure lower and more constant and does not allow it to be easily disturbed by reflex irritation. Pharmacologists say that the iodides have no specific action on the arteries. They produce their effect, however, and probably act through the nervous system. The salt of iodine to be employed depends on the condition of the patient. Potassium iodide is most depressing, and should not be given whenever there is cardiac insufficiency already existent. Hydriodic acid is the least depressing and serves best whenever there is gastric irritability. It may be given in the syrup of hydriodic acid in doses of two to four drams three times a day. Compensatory hypertrophy is Nature's remedy for the arterial degeneration, but Nature is too prodigal in the matter and the consequent discomfort may be lessened by cold to the precordium. Sparteine sulphate in doses of one-eighth of a grain is a good heart tonic without being a stimulant in these cases.

Heart Stimulants.—All heart stimulants should be used carefully. If heart compensation is good, digitalis is contra-indicated. In failure of compensation this is of great value. It should be given for a week, or even for a month if needed. Small nightly doses three or four times a week serve to keep up the heart nutrition. Iron and cod-liver oil should be given freely and in general nutritive remedies employed as soon as any retrograding of the general condition is noted.

In the discussion, Dr. Quimby of New York said that the important element of these cases is to keep up the nutrition of the heart and blood-vessels. While inheritance plays a prominent rôle in these cases much of the tendency to degeneration is acquired. The fibrous change that is noted in heart and blood-vessels comes only when there is failure of nutrition. Fibrous tissue lives at a lower stage of nutritive vitality than muscular tissue and so replaces the muscular tissue when conditions are not favorable to the life of the muscle cells. Fibrosis in these cases is, then, rather a pathetic than a pathic change.

Heredity and Degeneration.—Dr. James J. Walsh of New York said that heredity, not by actual transference of diseased conditions from

one genertion to another, but by transmission of the tendency to degeneration, is undoubtedly the most important factor in these cases. Longevity is eminently a matter of family peculiarity. Only those live long whose ancestors have lived long. Early degeneration of arteries in one generation portends a like condition in the next. It is worry, and not work, that kills. Children of parents whose arteries have degenerated early in life should not be allowed to take up occupations that are especially liable to be accompanied by emotional disturbances. The family doctor should advise such people from being brokers or actors or even perhaps doctors, since, as Dr. Nammack has pointed out, the physician's life is liable to be so subject to worries.

Arteriosclerosis and Neurasthenia.—Neurasthenia is a word that in our day covers a host of various affections. Neurasthenia pure and simple, that is, functional deterioration of the nervous system as the sole basis of symptoms, is not nearly so frequent as has been thought. Very often it will be found that the vague pains complained of by neurasthenics, the tendency particularly to constriction of the thorax with more or less localization of the discomfort in the precordial region, are usually due to some disturbance of the circulatory system. In dispensary work, especially among patients who came originally from the center of Europe, there are many cases of apparent neurasthenia. Patients have been accustomed to an absolute outdoor life in Europe, and here in sweatshops and tenements live an absolute indoor life. This rightly forms a basis for true neurasthenia, yet very seldom will cases be found in which there is not some organic basis for the disease. Early degeneration of arteries in the hurried bustle of American life is the true American disease rather than neurasthenia.

Cardiac Pain and Gastralgia.—Dr. Charles G. Stockton of Buffalo said that it is not an unusual thing to find a case of acute dilatation of the heart associated with so much pain that it is considered to be true gastralgia and the patient is treated for gastritis. This may be the only symptom severe precordial pain. Very often the severe symptoms come on only after very extensive degeneration of the arteries has taken place. Dr. Stockton has seen a case in which rupture of the heart has taken place, with so few preliminary symptoms of cardiac disturbance as to make it a distinct surprise.

Corrosive Sublimate.—Dr. Frank W. Higgins of Cortlandt said that Professor Thompson used to advise corrosive chlorate of mercury in small doses for cases of arteriosclerosis and consequent circulatory symptoms. This is an old remedy, but Dr. Higgins has found it more satisfactory than many a drug of more recent suggestion. Of late, Dr. Higgins has tried bromide of gold and arsenic in these cases, but his results have not been very satisfactory and he would like to know how they had acted when administered by others.

Employment of Digitalis.—In closing the discussion, Dr. Nammack said that digitalis was not indicated in the first stages of the disease, but that in the third stage, when failure of compensation occurred and dilatation of the heart with ascitis and other accumulations of serous fluid in the tissue, it is the most important drug that we have. With regard to the mercurials, he prefers calomel to the corrosive chloride of mercury, and usually uses it in conjunction with digitalis and squill in the form of the well-known Niemeyer pills, this remedy with sulphate of magnesia gives great relief in these cases. The mercurial, of course, must be used intermittently and then the infusion of digitalis is employed.

Dr. Delancey Rochester said that in the terminal stage of arteriosclerosis, with collections of fluid in the body cavities and the areolar spaces, the patient needs rest and not digitalis. The patient should be put to bed and all the arteries should be relaxed. The emunctories should be thoroughly opened. Fluids should be removed by excretory methods or by cannula. Instead of digitalis, Dr. Rochester uses the fluid-extract of cactus, Merrill's preparation, though this is not employed continuously. Nux vomica is employed as a heart tonic and is much better than any heart stimulant. Dr. Rochester's experience with arsenic and gold salts has not been satisfactory.

Dr. LeFevre does not believe in digitalis in heroic doses. In small doses it undoubtedly does good. Nux vomica is of service in these cases, but it acts not directly as muscle tonic, but as a nerve tonic. By its use we cannot increase the nutrition of the heart muscle, as we can with digitalis. The careful use of digitalis undoubtedly prolongs life.

Blood-examinations in General Practice.—Dr. Frank W. Higgins of Cortlandt described some methods of blood-examination that may be used by the general practitioner and detailed the information that could be derived from them. For the specific gravity of the blood he considers Hammerschlag's method reliable and practical. A mixture of chloroform and benzine is used, the amount of the two ingredients being so regulated that a drop of blood will just float in the mixture. The specific gravity of the mixture will then be the specific gravity of the blood. Care must be taken that no air clings to the drop of blood and the determination must be made before any changes have been induced in the blood by the chloroform benzine. There should be no water on the top of the mixture or this will cause loss of hemoglobin and consequent disturbance of the specific gravity. There are rather wide variations in the specific gravity of the blood in health. The specific gravity of the blood corresponds very closely to its hemoglobin contents.

Hemoglobin Determination.—The methods for determining the amount of hemoglobin in the blood are the least accurate in scientific blood estimation. It depends on the recognition of fine

gradations of color and males do not possess a good color sense. Fleischl's is the best instrument for the purpose. The determination of the hemoglobin in the blood is of value in the differential diagnosis of pernicious anemia from cancer. In pernicious anemia the amount of hemoglobin present is more than would be expected from the number of red cells present. The only diagnostic method for the recognition of leucemia is by counting the white cells present in the blood. The number of white cells also decides the amount of leucocytosis, and leucocytosis has become an important diagnostic feature in recent years. Whenever acute suppuration takes place in the body, leucocytosis showing 12,000 to 50,000 white cells per cubic millimeter is to be found. In intestinal perforation in typhoid the occurrence of leucocytosis is almost pathognomonic, because typhoid fever itself is almost the only acute infection in which no leucocytosis takes place. Leucopenia, that is to say, a lessened number of white blood-cells than normal, occurs in intense septic infection and is sometimes of service in the diagnosis of cases where it is difficult to obtain a history. In blood-counting the leucocytosis that occurs after anesthetics is transient and so is not liable to produce confusion with septic conditions. In conditions of abscess or gangrene the leucocytes are always increased in number. In pneumonia marked rise in the number of leucocytes indicates a favorable prognosis. This is not a difficult procedure and is extremely important for the diagnosis of anemic conditions. In pernicious anemia the red cells are found distorted and poikolocytosis always means a grave anemia. The presence of megaloblasts, that is, of large red cells containing nuclei, is an index of a fatal type of anemia. For blood staining Erlich's tri-acid solution is the best. When this is carefully applied and the staining is good and clear, a lens with a one-fifth of an inch focus is quite high enough power for the study of the stained cell. The differential blood-count is not difficult and sometimes gives precious information in annoyingly obscure cases. Eosinophilia is a pathognomonic sign of trichinosis and justifies the cutting out of pieces of muscle for examination for the parasite.

Simple Blood-method.—Dr. Richard C. Cabot of Boston said in the discussion that he was a general practitioner himself and that any general practitioner might readily study the blood to advantage. For the determination of the hemoglobin in blood he considers that Talquist's apparatus is quite sufficient; it costs a dollar and a quarter and the examination takes about five seconds; it is accurate to at least within ten degrees. The determination of the specific gravity in the blood is not of sufficient clinical value to make it worth while. The presence of leucocytosis may mean pus and taken in conjunction with other symptoms it must not be considered of itself, however, absolutely to denote the presence of a purulent condition.

Tuberculous Glands of the Neck.—Dr. Syms of New York read a paper on the conservative surgery of tuberculous glands of the neck. Dr. Syms does not believe in the radical operation save in certain selected cases. It does not save scars, but replaces several small scars by one long, and usually much more noticeable, scar. The so-called radical operation also increases the danger of general infection and it decreases the resisting power of the individual at a time when there may be little resistive vitality. The radical operation has a place in surgery if glands are breaking down continuously and fresh glands are progressively infected and if the general health is being undermined by the pathological process that thus persists. The most important thing is the general treatment of the patient's conditions. They should be advised to be out-of-doors all the hours of sunshine, they should sleep with the windows wide open and be well covered, and should have a warm room in which to dress and undress. Their digestion and bowels should be carefully regulated and milk should be given between meals and on retiring. They should be given the syrup of the iodide of iron, and should be made to retire early and sleep long.

Local Treatment.—When glands become enlarged they should be covered with a ten-per-cent. ichthyol ointment at night and this should be washed off in the morning. If one or more glands remain obstinately enlarged these should be removed. If glands begin to break down an incision should be made into them before the capsule ruptures. A surgeon should be careful not to permit the development of periglandular infective processes. After incision has been made into the gland it should be kept open by gauze for some time until all of the broken-down material has been discharged.

President's Address.—Dr. John A. Wyeth of New York, the President of the Association, then delivered the Annual Address, the subject of which was "Comments on Some New Surgical Methods." With regard to medullary narcosis Dr. Wyeth is of the opinion that it has come to stay and will form a useful procedure for modern surgery. When patients have affections of the kidneys that contra-indicate the use of ether, the injection of a fifth of a grain of cocaine into the spinal cord will secure the necessary anesthesia. In obstetrics, also, this method has been found useful, though the use of chloroform has been so safe in midwifery that any other anesthetic method seems superfluous.

Cocaine can be sterilized by being placed in a test-tube and plunging the latter into boiling water. This does not destroy the anesthetic power of the cocaine. The needle is inserted between the fourth and fifth lumbar vertebræ and is pushed inward and upward. In especially sensitive patients local anesthesia by cocaine or eucaine may be employed for the cutaneous and immediately underlying tissues. About as many minims of the cerebro-spinal fluid should be allowed to escape as are to be injected of cocaine

solution; that is usually about ten drops. The injection should be made slowly and the insertion of the needle into the meninges should also be made slowly. In an old case of Pott's disease in which the lumbar vertebræ were soldered together, Dr. Wyeth has succeeded in securing spinal anesthesia by injection between the tenth and eleventh dorsal vertebræ.

Occlusion of Carotids for Neoplasms.—Dr. Wyeth has been very much interested in the method of treatment for inoperable malignant tumors of the larynx and pharynx by cutting off their blood-supply. This is done by tying the carotid on the affected side. Dr. Wyeth has experimented on animals with the hope of finding some substance which, when injected into the vessels, would bring about their occlusion. Alcohol did not produce closure of the vessels. Melted paraffin proved very satisfactory and was associated with no annoying complications, such as gangrene. Boiling hot water causes clotting where injected and closure of the vessels, but it is followed by gangrene.

Boiling Water as Surgical Aid.—As the result of his experiments Dr. Wyeth resolved to use boiling water for the obliteration of a very disfiguring nevus of the lip in a young woman. A previous attempt at its removal by the knife led to serious bleeding. Part of the vascular growth was injected with hot water with subsequent atrophy that was very promising. Three large syringefuls were then injected into various parts of the growth with the result that it all atrophied. Pressure was exerted all around the growth during the injection to prevent clots being carried into the general circulation. The tumors continued to atrophy for some time after the operation and the patient now considers herself cured. The disfigurement is entirely gone.

Perineal Prostatectomy.—Dr. Wyeth considers that the development of the operation of prostatectomy is due to American surgery. Perineal prostatectomy, wherever possible, remains the operation of choice. The death-rate of this operation has decreased very materially of late years, owing to the skill of surgeons and the better technic. The progress in this special department of surgery represents some of the best work done during the last ten years.

Ovariotomy for Mammary Cancer.—Beetson, an English surgeon, removed the ovaries in a case of inoperable malignant disease of the breast. The mammary tumor decreased in size after the ovariotomy and the relief proved permanent. This operation has now been done a number of times, and in some cases at least has proved life-saving or has prolonged life and ameliorated symptoms. Just what cases it is best suited for has not yet been determined. Inoperable mammary cancer is such a hopeless condition that a simple non-dangerous procedure like this must be tried for its possible curative effect in every case.

Iodophilia.—Dr. Richard C. Cabot of Boston described this phenomenon, the occurrence of brownish granules in the white blood-cells when the blood is mixed with iodine and viewed under the microscope. The technic of the production of the iodophilic reaction is extremely simple. A drop of a mixture containing one part of iodine, three parts of potassium iodide and 100 parts of water with sufficient gum Arabic to make the solution mucilaginous is placed on a microscopical slide. Over this a cover-glass with an ordinary blood-smear as prepared for microscopical purposes is placed. Within a few seconds the iodophilic reaction can be seen if it occurs. The occurrence of this reaction in the white blood-cells used to be considered indicative of glycogen. Pure glycogen, however, dissolves in a solution of this kind and so it is not a glycogen reaction, though we do not as yet know just what causes it. It is nearly like the reaction that occurs in tissues where amyloid degeneration is present. All that can be said is that it is an iodine reaction. These are rather wide, but are definite enough to give valuable information. In general it may be said that the iodophilic reaction occurs in anemia, suppuration gangrene, or toxemia. Possibly all the conditions mentioned might be included under the single word toxemia. In brief the reaction tells us whether a patient is sick or not. This is important because, while there may be severe subjective symptoms, there may be no serious pathological conditions present. Our more exact methods of diagnosis are mainly for this purpose. We know that if a febrile temperature or albuminuria is present our patient has a serious condition. For a time it was considered that iodophilia, like leucocytosis in acute cases, meant pus. In connection with other symptoms it may be useful in the diagnosis of the development of purulent conditions, but alone it has not such special significance.

Practical Value.—Dr. Cabot related some cases in which iodophilia was of practical value. In a case admitted to the Massachusetts General Hospital, there was some tenderness of the abdomen, some pain, marked prostration and a tendency to collapse in an extremely anxious patient. The symptoms were very indefinite and the diagnosis seemed to lie between abdominal obstruction, pancreatitis, or peritonitis. With a low leucocytosis the iodophilic reaction was marked. The suggested diagnosis was peritonitis and the operation proved its correctness. In difficult appendicitis cases, the reaction is always useful, its presence being significant of a serious condition. For the differential diagnosis of serous or purulent empyema, iodophilia is almost pathognomonic.

Leucocytosis and Iodophilia.—Two years ago Dr. Cabot thought that iodophilia and leucocytosis went together. Now he knows that one may be present without the other and that this peculiarity may be of diagnostic significance. In two cases of extra-uterine pregnancy, for instance, there was a leucocytosis of over 20,000. This with the pain and other symptoms would

almost surely suggest the presence of pus. Iodophilia, however, was negative and the condition found was non-purulent. In a recent case there was pain in the shin-bone and the X-rays showed a shadow on the plate. The iodophilia was negative, showing that there was no pus, and at operation an exostosis was found. Iodophilia is never present in rheumatism and in a recent supposed rheumatic case where the reaction was positive the autopsy showed a pyemic condition of the joint.

The Laboratory in Surgery.—Dr. Simon Flexner of Philadelphia said that if the true value of the laboratory is recognized, its financial support will be insured. In order to secure this, however, it must be well managed. The laboratory is no longer a merely theoretic, but a thoroughly practical institution. The study of the edge of a malignant growth, for instance, may show that there are malignant elements at this point and indicate a certain return of the tumor. In certain neoplasms the morphology of a tumor may show to the trained microscopist that it is secondary and not primary and the original malignant neoplasm may prove to be in the prostate, in the nose, or in some other organ. In not a few cases, staphylococci and in rare cases even streptococci have been found in the blood. The significance of the presence of these bacteria is not yet entirely made out, but we know now that they do not necessarily imply an unfavorable prognosis. Patients may recover if the original focus of infection is in a position where it can be readily evacuated. Presence of bacteria in the blood means nothing unless they grow there. Typhoid bacilli frequently occur in the blood, but only rarely grow in it. In cases of varix the microscopical examination of removed blood-vessels showed the filarial origin of the condition in a case examined by Opie and in a recent case of Flexner's own. Leucocytosis, of course, is important in showing the presence of pus, though it fails to occur in intense cases of purulent generalized infection. Eosinophilia has come to be a recognized condition in trichiniasis and a pathognomonic sign of the affection. We are evidently only on the threshold of the progressive usefulness of the laboratory in practical medicine and surgery.

The Laboratory and Recent Modifications of Surgery.—Dr. Joseph D. Bryant of New York detailed some of his experiences as house surgeon at Bellevue thirty years ago, in order to bring out the difference between the methods of then and now and the improvements consequent upon the extended use of the laboratory in surgery. At that time many cases in the hospital for surgical reasons developed erysipelas. Pyemia was frequent. Carbolic acid, opium and balsam of Peru were the drugs most commonly prescribed, but anything like a hint of the principles of antisepsis was unknown and asepsis was unthought of. In six months of the surgical service nine patients died from pyemia as the result of compound fracture and amputation. In Dr. Bryant's eighteen years' experience as a visiting surgeon there have not been an equal number. Antiseptics were used blindly and inefficiently. Dr. Bryant still has the notes of some cases and their treatment. In 1871 he personally applied Lister's lac dressing. This was the first time it was ever applied in America. Lac plaster was made of carbolic acid and shellac and was poured upon the wound with the idea of acting as a protective; any idea of true surgical cleanliness was not yet in surgical minds.

Surgical Hesitation.—The marked feature of the surgical service was the hesitation of surgeons to interfere in many cases that are now operated upon at once. Dr. Bryant remembers a case of rupture of the bladder into the peritoneum. The bladder was drained by a catheter, but nothing further was done and the patient died, as might have been expected. The expectant plan of treatment was the rule then, and the mortality of such accidents was 95 per cent. Now over 60 per cent. are rescued. A patient suffering from extraperitoneal rupture of the bladder was admitted to the hospital, but nothing was done to repair the viscus. Abscesses were opened when they formed. A constant state of suppuration proved exhausting to the patient, and at the end of six weeks death ensued. These wounds were treated absolutely expectantly, surgeons being very timorous about opening the peritoneal cavity. The patient was put under the influence of opium and an expectant attitude maintained. Dr. Bryant recalled a case in which bloody urine was a feature, but the only surgical interference attempted was drainage of the bladder by a catheter. Needless to say most of the cases perished. The mortality was over 90 per cent. Now over 30 per cent. recover under surgical treatment.

Intestinal Obstruction.—Dr. Bryant recalls a consultation of the visiting surgical staff over a case of peritonitis that had developed as the result of intestinal obstruction. There was a history in the case of no movement of the bowels for seven days. The abdomen had become tender and swollen and the distention had become extreme. Vomiting that finally became fecal in character was established shortly after admission to the hospital. It was not until the fourth day that a consultation was held. Nothing was done as the result of the consultation, and at the autopsy strangulation of the small intestine was found. Thirty to 40 per cent. of such cases are saved now.

The Pneumatic Cabinet in Heart Disease.—Dr. Quimby of New York read a paper on the use of the pneumatic cabinet in the treatment of diseases of the heart. He uses a differentiation of pneumatic pressure in order to relieve many of the symptoms that occur during the course of heart disease. The patients breathe in air at a normal pressure and breathe out air at lessened pressure. The result of this treatment is not only the relief of symptoms, but also a tonic effect is exerted upon the heart that makes the

heart muscle much more capable of performing its work and is almost curative in character. Dr. Quimby exhibited the sygmographic tracings of a series of patients who had been treated by the differential pneumatic pressure method. All of them showed not only that the patients were relieved for the time being from their irregular heart action, but also that at successive séances of the treatment there was progressive improvement. Patients came back in better condition each time and went away still more improved until, finally, the relief afforded amounted, in the patient's mind at least, to a cure. There was during the progress of the treatment a noticeable change in the character of the physical signs of the heart and an evident modification of the valvular lesions in the cases as the result of the mechanical help afforded by the differential pneumatic experience.

Gunshot Wounds of the Hip-joint.—Major Louis A. LaGarde of Washington, D. C., read a paper describing the effects produced upon the hip-joint by the entrance of projectiles of reduced caliber. The old army rifle of the Civil War projected a 40 to 50 caliber bullet that weighed twice as much as the modern bullet of a 26 to 30 caliber. The old bullet was made entirely of lead and was flattened and shattered against hard tissues, making a crushing wound. Injuries of large bones and of large joints were then very serious. Besides, the old bullets were of lower velocity and so made a much less clean-cut wound. The modern bullet revolves on its axis 2,400 times a second at its exit from the rifle, the old bullets revolved only 800 times per second. Besides the smaller size and weight of the modern bullet for carrying purposes they are encased in a steel capsule. If the end of this capsule is filed off, leaving the lead exposed, when the bullet impinges against a hard substance, an explosive effect is produced. Under ordinary circumstances, however, the modern bullet makes a clean small hole through a bone. Dr. LaGarde exhibited some specimens of tibiæ and femora, showing how little splintering effect had been produced by bullets fired from cartridges with limited charges. They make a clean-cut, punched-out wound. Dr. Stevenson of the British Army in South Africa says that he has seen a number of hip-joint bullet-wounds recover without complications and without a sign of pus. There is undoubtedly penetration of the joint tissue, and yet in many cases the X-rays show nothing and they proceed to get well. During his experience in South Africa Dr. Stevenson has seen only three amputations for wounds of the hip-joint and only one of these resulted in death. It is evident, then, that the modern small-caliber bullet, while not intended originally to reduce the amount of suffering or injury produced, but adopted because of its better carrying power, is about to make the surgery of war easier and the danger of bullet-wounds in bones much less than before.

Asthma Not a Nervous Disease.—Dr. G. N. Jack of Depew, N. Y., read a paper in which he argued that asthma was due not to a nervous condition in the lungs themselves, nor to any reflex nervous condition outside of the lungs, but to instability of the blood. This instability of the blood is mainly due to intestinal toxemia. Absorption of illy-digested material from the gastro-intestinal tract has its effect upon the delicate lung-tissue and this gives rise to the asthma.

Diathesis in Asthma.—Asthma occurs with special frequency in patients suffering from a lymphatic diathesis. There will often be found in these cases an asthmatic lymphocytosis. The sudden death that occurs in the lymphatic diathesis is often due to a drowning of the patient in his own secretions. The cyanosis and excessive secretion that sometimes occur spasmodically even in young persons may be relieved by Epsom salts, which clear the blood of excrementitious material and so relieve the tendency to pulmonary spasm.

Vasomotor Paresis as Cause of Asthma.—In the discussion of Dr. Jack's paper, Dr. George Cott of Buffalo said that the most satisfactory explanation of the cause of asthma is that it is due to a vasomotor paresis. The reflexes that arouse this palsy of pulmonary terminal filaments need not necessarily be situated in the lungs or even in the respiratory tract, but may even come from the intestinal mucous membrane. Improvement of digestion, then, will lessen the number of attacks of asthma or cure the disease. This does not prove, however, that a better condition of the blood relieves asthma, because the cause of the asthma is in the blood. Improvement in the patient's condition causes less irritability of nerves and so lessens asthmatic attacks.

FOURTH DAY—OCTOBER 24TH.

Differential Leucocyte-count.—Dr. William G. LeBoutillier of New York City read a paper on the differential leucocyte-count in fractures. The fact that the bone-marrow is a blood-making organ might lead to the thought that there would be some marked differences in the differential leucocyte-count after fractures. Dr. LeBoutillier has investigated the question and finds that there is no special alteration in the proportion of various kinds of leucocytes during convalescence from fracture. There was a distinct rise in temperature after even simple fracture that continued as long as ten days to two weeks after the fracture and amounted to several degrees. Only in two cases were there marked differences in the leucocyte proportions and these were alcoholic cases in which sepsis and death followed. Myelocytes were more frequent than normal, but this was of no special clinical value.

Malposition of the Gall-Bladder.—Dr. E. D. Ferguson of Troy described some anomalous positions of the gall-bladder that have especial interests now because of the frequency of opera-

tions in the biliary tract. While the gall-bladder is said to be situated always in definite opposition between the right and left lobes of the liver, the complicated developmental processes of this portion of the body might be expected to bring about the displacement of it not infrequently. While much has been said of the burying of the gall-bladder in the midst of adhesions, very little has been written about its possible anomalous position. The liver develops from two buds of embryonic tissue that gradually grow together, and between them the gall-tract is formed to find its proper place beneath the two lobes of the liver after their union. The simultaneous development of the omentum and peritoneum at this part makes the problem of ultimate position an intricate one with many possible disturbing factors.

Extraperitoneal Gall-bladder.—Dr. Ferguson described three cases in at least two of which the gall-bladder seemed to occupy a position behind the liver and outside of the peritoneal cavity. In one case the gall-bladder lay distinctly behind the liver and was extremely difficult to get at. In another case the gall-bladder formed a rather large sausage-like tumor behind the colon in the retroperitoneal space. It is evident that the study of anomalies of the gall-bladder will be of immense practical importance and that all observations in this matter should be carefully noted. As for the appendix, surgical interest will doubtless bring us the realization that there are a number of positions in which the gall-bladder may be as the result of embryological peculiarities, and that the surgeon must be prepared for anomalous symptoms.

Prostatic Obstruction.—Dr. J. W. S. Gouley of New York read a paper on the treatment of prostatic obstruction to urination by enucleation of the diseased part. He said that the operation for relief of prostatic obstruction should not be too long delayed. The operation should not be called prostatectomy, which is a wrong term, because the whole of the prostatic structure is never removed, but only the obstructing parts enucleated. Dr. Gouley exhibited a new form of prostatic retractor by which the enucleation of obstructing prostatic tissue would be facilitated.

Selection of Operation.—Dr. Parker Syms of New York said that we owe more to Dr. Gouley in the development of the proper surgical treatment of prostatic obstruction than to any one else in this country. The mortality was high at first, because operative interference was suggested only in the case of feeble old men, in whom it was proposed as a last resort. Dr. Syms considers that the perineal route is less dangerous than the suprapubic method, because it provides a simple straight wound and drainage by gravity. Dr. Syms presented a rubber bulb and tube retractor, by which the bladder can be pulled down and the prostate made more accessible. With this instrument he has done prostatic enucleation in twelve cases without a death.

Dr. Eugene Fuller of New York said that the operation in any given case must be selected according to the individual peculiarities of the case. At tmes undoubtedly the suprapubic route is the best. If the prostate is very large, weighing over half a pound, it is an extremely difficult matter to remove it through a perineal incision; if, as not infrequently happens in old prostatic cases, there is a large hard stone present, the suprapubic route is the operation of choice. In one such case seen recently Dr. Fuller has not hesitated to do a second suprapubic operation in order to remove a stone when necessary.

Vesical Emergencies.—The most important of these, according to Dr. Eugene Fuller, are due to retention of urine. There are two classes of cases—those in which catheterization is possible and those in which it is not. It must be borne in mind that distention causes spasm and tenesmus, and there must be no forcible effort at catheterization. A gum elastic stiffened catheter, olive-pointed, is the best for these cases. Where this will not pass a filiform bougie should be employed. As the opening in the stricture of the urethra may not be exactly in the center, this should be bent at various angles. If a filiform passes, the urine will usually escape alongside it and the patient may be put to bed and the bladder distention will relieve itself. If not a tunnel cavity can be employed. Where this fails suprapubic aspiration should be employed. After relief of bladder distention by aspiration a catheter may be passed.

Uterine Prolapse.—Dr. Frederick Holme Wiggin said that this is really a hernia and, in treating it, the hernial sac should be obliterated. For this a laparotomy should be done in the Trendelenburg position and purse-string sutures inserted in the uterus and the broad ligaments so as to give the uterus a new insertion near the base of the ligament. Patients should be kept in bed for four or five weeks, at the end of which time the vaginal redundancy will have disappeared and the muscle of the pelvic floor may then be brought together. Dr. Wiggin has used this method with satisfaction in patients from seventy to eighty years of age.

Typhoid Cholecystitis.—Dr. Charles G. Stockton of Buffalo detailed some cases in which an inflammation of the gall-bladder occurred as the result of infection with typhoid bacilli. In the first of the cases the symptoms referable to the gall-bladder developed 100 days after the beginning of the attack of typhoid fever. The typhoid had run an anomalous course with relapses; the first symptom of the attack were severe epigastric pains that compelled the patient to go to bed. These were localized in the right hypochondriac region. The abdomen was tender, especially in the upper part. The gall-bladder was not palpable. The temperature was 104° F. and the pulse 120. The patient had two severe chills the first day. Intense cyanosis developed, involving the lips and the nails. The stools were bile-stained and contained mucus.

During the course of the attack herpes zoster developed on the right arm. The Widal reaction, which had only been dubious before, then became positive. The attack was followed by the passage of a gall-stone.

Characteristic Case.—This patient was taken with pain in the right hypochondriac region that radiated upward toward the shoulder. When put to bed the pain subsided, but recurred when she went to work. There was tenderness over the liver. The Widal reaction was doubtful, the blood-counts showed a leucocytosis of 18,000. On the seventeenth day after the beginning of the attack jaundice developed. This came and went in a remarkable way. The irregular temperature course led to the conclusion that pus was present. The gall-bladder was opened by Dr. Roswell Park, but contained only viscid mucus. The gall-bladder was surrounded by recent adhesions. After the operation the temperature at once declined and cultures taken from the contents of the gall-bladder showed only the presence of typhoid bacilli. In a third case a husband had died with typhoid and four days after his death the wife was stricken with backache and headache and a temperature of 104° F. The Widal reaction showed a loss of motion in the bacilli, but very poor clumping. Nearly two months pased before the reaction became positive. On the twentieth day the patient developed a severe chill with some jaundice. An attack resembling gall-stone colic occurred and a gall-stone was passed. Leucocytosis was also present in this case. In these cases, except the first one, which developed very late, the average time of development was about the twentieth day; this is also the average time of development in a large series of cases.

Pain in Cholecystitis.—The presence of pain with infection of the gall-bladder does not necessarily mean the presence of calculus. Dr. Ferguson of Troy said that Kehr, the German authority on gall-stone surgery, believes that cholecystitis causes spasm and consequent pain without the presence of stone. Dr. Stockton in closing the discussion said that Naunyn, the great German medical authority on biliary conditions, considers that it is the inflammation set up by the stone rather than the stone itself that causes the pain. He also says that cholecystitis is the mother of gall-stones.

Rheumatism versus Consumption.—Dr. Thomas F. Reilly of New York read a paper in which he discussed the protection afforded by the gouty or rheumatic diathesis against pulmonary tuberculosis. Nearly a century ago Louis, the distinguished French medical authority, believed in the opposition of the two conditions. Rokitansky at the middle of the century seemed certain of the same opinion. There is a certain tendency to fibroid conditions associated with the gouty and rheumatic diathesis that is strongly opposed to the development of tuberculous processes. In over 100 cases of tuberculosis careful examination of the history showed that, notwithstanding the fact that most of the patients were of the poorer class, had been exposed to the elements and to the inclemencies of the weather and had abused alcohol, only two per cent. of them had ever suffered from rheumatic symptoms. Other observers have called attention to this condition. Of late injections of urea have been employed with claims of good results as in pulmonary phthisis. The principle would seem to be that an excess of the products which cause rheumatic symptoms would be preventive or curative of tuberculous disease. Dr. Reilly called attention to the fact also that skin diseases usually considered to be associated with the rheumatic diathesis do not occur in phthisis.

Resection of Cervical Sympathetic for Glaucoma.—Dr. Wilbur B. Marple of New York gave the present status of this operation for glaucoma. In from 10 to 25 per cent. of glaucomatous cases no improvement is brought about by iridectomy. These cases go on to blindness in the midst of pain and intense discomfort. In 1896 experiments on animals showed that the section of the cervical sympathetic caused a decrease of intra-ocular tension with a smaller pupil. It was not until three years later however, that this fact was applied to medical practice. There was fear that section of the cervical sympathetic would cause trophic lesions in the eye and the side of the head.

Present Statistics.—Last year at the International Congress for Ophthalmology 74 cases of sympathectomy for glaucoma were reported. To these Dr. Marple adds 13 cases. Unfortunately, many of the reports of success in the operation come too soon after its execution to give any idea of its ultimate success. The disease is essentially chronic and in some sympathetic resection is followed by improvement, yet the improvement is not permanent. Up to this time we are not sure in what cases sympathectomy is indicated, or in what cases permanent good results can be expected. When excavation of the papilla with atrophy of the optic nerve has taken place little improvement can be looked for. Meantime we must wait and sift cases.

Cervical Resection.—Dr. James J. Walsh of New York said that, in a recent communication from Professor Jonnesco, that surgeon stated that cases operated on by this method for glaucoma in 1897 had retained the improvement that came after the operation. In Professor Jonnesco's hands the operation has been useful not only for glaucoma, but also for exophthalmic goiter. In cases where the exophthalmos is very marked and there is danger of loss of the eye from failure of the lids to cover the protruded globe, cervical sympathectomy saves the sight, the exophthalmos grows less, the goiter decreases and the rapid heart action is diminished. in closing the discussion, Dr. Marple said that Professor Jonnesco's cases are reported entirely too meagerly to enable us to judge, either of the conditions existing before or of the improvement that took place or of its permanency.

SOME FURTHER REMARKS ON HOSPITAL AND DISPENSARY ABUSES AND MISMANAGEMENT, WITH AN ACCOUNT OF THE MEANS TO BE EMPLOYED TO MITIGATE OR ARREST THEM.[1]

BY THOMAS J. HILLIS, M.D.,

OF NEW YORK.

Is IT putting a premium on pauperism and an outrage on the honest man to permit a system that dumps into the ward of a hospital an assassin and a thief, and places between those malefactors a citizen who came to the hospital in good faith, and, as a guarantee of which, paid his board in advance?

A burglar made a daring attempt to rob a house, but only succeeded in killing the proprietor, wounding the latter's son and desperately injuring himself. The assassin and his victim are carried by the ambulance to the hospital, and, as likely as not, may be laid side by side in the ward. With the wounded men comes an officer of the law to keep guard lest the assassin escape.

The privacy of that ward is invaded by a thief (who is also a murderer) and a police officer. There are patients in that ward who pay their board, and others who don't, some of whom are very low, suffering from shock and other causes incident to disease. Nerves there are there racked with pain, and hearts which ache. Now, to increase this suffering of those afflicted people, right in the midst of them an assassin and a policeman are placed.

This brutal and excuseless outrage (which among a spirited people ought not to be tolerated for an hour) is being enacted many nights and days in some one of our city hospitals under the eye of the superintendent, and no doubt through the order of the Board of Trustees, who wish to be known as men of fair dealing and public-spirited citizens. Have those ward-patients any rights that the trustees should respect? It appears not. Let us take a case in point.

The daughter of the president of the Board of Trustees of one of those hospitals of which we speak is convalescing from the effects of a severe attack of typhoid fever in her comfortable private room. What would her father say to the superintendent if he permitted a group of students, under the leadership of their professor, to invade her room for the purpose of further diagnosing her case? He would ask for his resignation, and request that it should take effect immediately. Yet, this offense of the superintendent is only a minor one, easily condoned, compared with the flagrant outrage he caused to be committed in the ward of the hospital he controlled by the presence of a burglar and a policeman.

The woman, whose sister is a seamstress, and who works until her head reels, and her eyes are red from worry and weeping at her hard lot, is spunky; she has sand in her, and wishes it to be known that her sister is no pauper and does not belong to the brigade which pays no board to the hospital. Nevertheless these are her companions in the ward, but the Trustees, those humane and intelligent gentlemen who drive murderers and policemen into the wards, wish to suppress the fact that this clever little woman pays her sister's board. Why? Simply for the reason that it might hurt the feelings and jar on the nerves of the dead-heads and paupers who are permitted, through their courtesy, to occupy the ward with her.

It might be worth while remembering that most of those dead-heads, and some of the so-called paupers, have money in bank, but such a little thing as this has no concern for the Trustees or the management. The pauper got into the ward somehow, and, being there, is invited to share in common with those who pay their board all the blessings and privileges that the hospital can bestow.

Is it honest on the part of the Trustees to hide the fact that the seamstress's sister is paying her way at the hospital, and to have her sup from the same cup and eat from the same dish with a criminal or a pauper, who may be reclining on a cot on either side of her? It is a dishonest, immoral and a criminal act for which the writer of this article holds the hospital authorities directly responsible.

This very intelligent Board of Trustees is quite interested in the patients in the wards who pay no board, so much so, that the fact that they don't, is visited with swift punishment on him or her who reveals it. There is no doubt that the superintendent, speaking for the Trustees, will again put in the same threadbare old plea he has done before, that each patient in the ward gets a food suitable to his case; that the physician in charge is alone the judge of this food as to amount and quality; that the standard of excellence is maintained for the wards as a whole, regardless of who pays or who does not pay; that the hospital reserves to itself the right to shield the affairs of a burglar or a beggar from inquisitive and prying eyes, and that the deficit is made up from the surplus of the hospital funds and gratuities. This is not true even in part, for the quality of food supply and manner of cooking fluctuate in most hospitals from day to day, being always affected by the prosperity of the hospital; the condition of its finances it reflects with great regularity.

[1] Read at the meeting of the New York County Medical Society in the Academy of Medicine May 27, 1901.

Anything, therefore, the superintendent will say about personal rights and individual obligations, besides a defense of the excellence of his culinary arrangements and quality and distribution of his food supply had better not be said.

In looking over the field of hospital mismanagement, and making due allowance for everything, the conclusion is irresistible that the hospital trustee who places the man or woman who pays no board, at a table with the man or the woman who does, no matter how plausible the pretext for doing so, is a promoter of social disorder and an advocate of mercantile dishonor, and does really as much to corrupt and disorganize society as a drunkard, bank burglar or the veriest common swindler, though he may be regarded as a magnanimous host by the crowd of dead-heads he harbors in the wards, whom he makes companions of decent people who pay him a weekly board-bill. No doubt the paupers in the ward count the Trustees as chivalrous; if so, it is the kind of chivalry indulged in by Robin Hood and other knights of the road in days gone by, and the kind of chivalry for which men are shot in Southern Europe and on the Mexican border to-day—the chivalry that suppresses facts, that enhances one's honor and exalts them in the community; that commits cold-blooded murder, and places a premium on hypocrisy and falsehood.

The hospital trustee will soon vacate the hotel in which he is comfortably housed if he has to "rough it" at the servants' table, and in the hotel corridors gets into a daily mix-up with all manner of people. On what ground will he base his action for leaving the hotel? Simply on this: That he paid a higher board-bill than the crowd with which he was compelled to mingle and that his necessities and creature comforts were leveled to theirs. He considers this a sufficient reason for vacating his quarters at the hotel, and it is. He found fault because others who paid less, and some who perhaps paid nothing for accommodations, fared precisely as he did.

Now, the thing he frowned on and expressed his disapprobation of, because it concerned himself, he endorses and stamps with the seal of his authority, because it is the affair of some one else. It would please the superintendent if the housekeeper would have roast lamb for dinner to-morrow for his hospital family. This, however, is out of the question for two reasons—roast lamb is dear and only 80 out of his 300 patients pay their board and lodging. If all paid he could afford to give them roast lamb and a plate of custard or jelly as dessert.

Now, 80 who have paid their board in advance must subsist to-morrow on a very inferior quality of boiled beef—the kind the boarding mistress of the cheaper class beats into tenderness with the blunt end of a hatchet—because there are 220 dead-heads in the hospital wards paying no board, whose sensibilities might be hurt if the 80 got some value for their money. Those 220 paupers have got into the wards through the tricks and devices of which we have spoken, and this crowd of mendicants spoil the chance of a good meal for the unfortunate 80 who have reason to expect better treatment. Now mind, gentlemen, this is not a charity hospital; if it were it would make the hearts of those dead-heads bleed to think it would become known that they were subsisting on charity. Of course it is not charity, but a poor substitute for it, introduced by the discreet Board of Trustees to cater to the depraved and the vicious, that it might enhance their standing in a community which owes them nothing.

The play was very humdrum and commonplace, and it elicited the disapproval of the audience, whose dissatisfaction was so pronounced that the manager had to come before the footlights to explain when he said that he did the best he could for the amount of money he got out of the audience, which was a large one, as only one out of four paid for a seat. It was a houseful of complimentary tickets he said, and even worse, the best seats were not occupied by the few who paid, but by those who cheeked it by telling a plausible story to the ticket agent at the box window, who was a philanthropist, for he believed the crowd who said it was impecunious but loved high art, and was eager to witness the exhibition from front seats, and complied at once with its modest request. After hearing the explanation of the manager, what a howl of dissent went up from the people who paid for their seats, and how loud the demand to get it back, what a cry of fraud, shame and imposition from the crowd of disgusted amusement seekers. But they have no more right to complain than the pay patients placed in the same ward with murderers, burglars, paupers and policemen, but they do demand a separate apartment and their demand will be heeded and complied with in spite of the protest of the governor and the pleadings of the trustees, all of whom later will follow into retirement the philanthropic ticket agent, whose business acumen ruined the reputation of his theatre, besides placing the manager in an embarrassing position before his patrons and the public. The preceding examples in illustration are deadly parallels and place the hospital governors, to say the least, in an awkward position.

I am aware that various and artful devices are brought to bear on the superintendent of every hospital in the city by unscrupulous applicants for free lodgings, and I think that he does not exercise sufficient judgment, that is business judgment (the thing he is supposed to be so plentifully provided with), otherwise he would see through an applicant's shallow pretext of one being worthy to sup with a person who makes sacrifices to pay his hospital for bed and board; he would see the diamond purposely hidden in the folds of the man's negligé shirt, or in the bow-knot of the woman's tie. We think he should see through the thinly-veiled disguise that those people were impostors who are laughing in their

sleeve at his verdure and credulity, but he is color blind for the convenience of the Board of Trustees, whose agent he is.

While preparing this article the writer visited one of our great public hospitals to look around the wards, when by accident his eye fell on a cot, the occupant of which he recognized; he was a prosperous truckman whom, he afterwards understood, gained admittance on the plea that he was poor. It was a visiting-day. Around his cot were several female friends, wearing expensive articles of apparel, on the fingers of whose hands the writer counted several brilliants. Those people came to buoy him up and brighten the horizon of his future with a light and pleasant jocularity, thus opening the way to a more rapid convalescence. This man left the hospital which he entered on the pretense that he was poor, though he owned several trucks, which fact was easy to ascertain, with his health restored after a sojourn of five weeks. If the superintendent observed his movements later, as I did, and followed the fellow about, he would hear the chimes or merry bells and see a church wedding and an elaborate breakfast in which a chef and three waiters played conspicuous parts, for the fellow got married to one of the diamond-bedecked females who came to console and congratulate him as he was emerging from the clutches of disease. But it was not disease at all, for he was only suffering from simple fracture of the femur.

The declaring of intentions and entering of pedigree, done at the superintendent's desk at present, is a farce—a little diversion preparatory to entrance—for it puts a premium on falsehood and offers inducement to honest folk to turn cheats. The lying done at the dispensary desk and up-stairs, at the more pretentious one of the superintendent, is something appalling and awful to contemplate. Ananias and Sapphira, though they stand through the ages as the synonym for falsehood, would be the merest amateurs if placed in that group of applicants, who to-morrow, will be clamoring for free treatment in every dispensary in the city. If this awful mountain of blasphemy, piled up by those people, male and female, for the purpose of saving the dollar, was a thing of substance that could be measured by tons, its weight alone would sever the earth's planetary consort, drive her from the solar system to be a wanderer through interstellar space, forever enveloped in frigid and cheerless night.

Effects of Unsuitable Food.—There is no doubt whatever that convalescence is retarded, if not death actually invited, by the milk treatment so prevalent in our general hospitals. The visiting physician does not look into this matter, we think, as carefully as he should, for after making a diagnosis of a case, that is, if it is not already made by his obliging interne, he leaves important details to subordinates who are known not to be overparticular about treatment, and give whatever is handiest, as the ever-ready milk and seltzer. The idea has gone abroad, and is still prevalent, that milk is easily digested; that it is nutritious, convenient to handle, and easily kept from spoiling, all of which is only partly true. If the stomach is in order, and in most of the general diseases, it holds its own, it can digest other kinds of food much more easily than milk. The fact that milk is difficult of digestion, that it clogs and constipates the bowels and acts as an irritant, is not reason sufficient with the superintendent to outweigh a further fact—that it is cheap and handy, because he has to fill so many mouths with so little money; it being remembered that he has on his hands (unfortunate man) 220 people—dead-heads—who pay nothing for their board and lodging, notwithstanding are yet dissatisfied and clamoring for better food; he is himself in a plight to make ends meet and keep up a decent appearance. Economy to him must be the first consideration and a vital factor it is to the successful administration of his office.

If all the patients in the hospital wards paid their board then he could afford to introduce a higher class of treatment, which in some cases has a value almost specific, but meat juices are too difficult to prepare and to keep ready, in addition they cost more than milk, so the superintendent cannot afford them, and since he cannot his patients must suffer.

It is now clear that the man or the woman who is compelled to occupy the same ward with two or any other number of people who pay no board at all, but are there by the option and pleasure of the trustees and overseers, are not fairly treated. The time is now ripe for a change to be made, and it is that men and women who enter a hospital and pay a weekly board-bill to the superintendent should be assigned to wards especially designed for them. If the management sees fit, it can receive paupers, but with the understanding that it will be in separate wards.

There should be three wards in every public hospital, or, if the trustees please, four, one for the pay patients, one for the insane who are able to pay their way and at the trustee's pleasure, two wards for the paupers, sane and insane. The introduction of a system like this will solve the vexed question and leave the hospital management in a position to do absolute justice to all. The long-suffering people who have paid for comforts they do not get may thus be housed in a separate ward, where the superintendent can afford to give them beef extract and bouillon in place of milk and seltzer—the ever-ready remedy for filling the stomach no matter what the disease or condition; no more dosing the patient with milk until he loathes it and turns away in disgust.

Intelligent and judicious sponging of the body is a means of reducing temperature that should receive more consideration than it does now. This requires time and close attention and the frequent use of the thermometer, but since the patient pays his board to the hospital, and the attending physician is accommodating enough to render free service, and the labor of the interne

and nurse costs very little, if anything, much time can be devoted to cases and much better results will follow.

The writer is aware of the small mortality record of the hospitals in their treatment of typhoid cases, but his own experience and careful observation of that of others leads him to look with suspicion upon any records kept in those institutions. For the no-pay patient or pauper the speaker will ask a similar treatment, one precisely like that given in the pay ward, but if for any reason (as lack of funds) it falls short, it is very proper that the shortage should occur here. Indeed, the very fact that high-class treatment will be expected, will be a potent factor to a greater caution and circumspection about admission and send many, now in the general wards, where they properly belong—to the City Hospital.

It is eminently proper that suitable provision be made for the insane in every public hospital in the city (and, indeed, other cities, if feasible) by the setting apart of a ward for that purpose. No good reason has at any time been advanced to show why this has not been done before. Those that have been put forward are so flimsy and unsubstantial that the writer does not think it worth while to discuss or refute them here, but weighty ones can be introduced to show its necessity. We can understand why contagious diseases are barred from our hospitals on the ground of public policy and the greatest good to the greatest number; but the insane man is not barred on this ground, but only that of expediency—a principle that at bottom is always selfish and narrow. From this cause great injustice is done to the sane public, and greater still to the insane, as people of moderate means are known to keep mad relatives around when their own personal safety is in jeopardy. This they do because they are cruelly denied admission to the general hospital; are afraid of the charity insane hospital (of which they hear such terrible things every day) and have not the means to reach a private insane asylum. Nor is the so-called private insane asylum much of an improvement on the scandalous city one, as their methods are about the same.

The fact that there are no public hospitals where the insane, especially the great throng who are only temporarily insane, can be treated is a great hardship to the people of this city. The absence of insane wards in public hospitals has led to all manner of abuse, and private asylums are now as liberally scattered over this city and its suburbs, principally the latter, where they are known by the more inviting cognomen of sanitariums, as pool-rooms and gambling-houses, and though doing much more harm than those places, we have never yet heard of a raid being made on them or of their being the subject of police investigation or surveillance.

What Should the Charity Patient Pay?—The pauper himself candidly admits that he owes a debt of gratitude to the people, who, through its municipal agents, picks him off the street or carries him from his cheerless garret, where he is sick and penniless, to a place prepared for him in the ward of a hospital. This debt the pauper cannot pay in money, and there is no other way of which we are aware but one (not by his prayers, which are of doubtful efficacy), and that is by submitting his person from time to time, without inconvenience or injury to himself, to examination by a group of medical students under the leadership of an accredited professor attached either to the college or hospital, or both.

This will be all that the people will ask of the sick pauper—a slight token of esteem from him to his benefactors. The accommodating spirit of the pauper will not affect his standing in society, lessen the esteem of his friends, nor affect his chances of preferment after recovery when he again mingles with the world of bustle and activity.

The condescension of the pauper, while not injuring himself, will directly benefit others. For instance, the students who have to learn somewhere and begin on somebody. He must begin here, for now, since the rights of pay-patients have been recognized, and they know his limitations, they will repudiate him, though he comes endorsed by the hospital governor and labeled with the stamp of the visiting staff.

Those pay-patients have memories of wrongs that will not wash out. The strain of clumsy manipulation and coarse banter to which they had to submit when herding with burglars and paupers under a régime, that has now passed away. The pay-patient remembers with a shiver when he was a shining mark for the professor's class of yearlings, who used him for a punching bag during their primary clinical rehearsals; they paid their respects to him rather than to the pauper, because he looked cleaner and had less odor than that individual.

After each of these examinations he was wont to have a hectic flush; a sinking at the epigastrium with dizziness and nausea. It is only fair to state that the professor's class was not permitted by the hospital governors to know whether one was a pauper or a guest of the institution, they—the governors—being so sensitive about the pauper's nerves, while not caring a rap about the health and happiness of honest men and women who go to their hospital and pay their way under the belief that they are sheltered by an institution which believes in fair play and recognizes the rights of person and property.

There are those who will claim equal rights for the sick criminal, but they do not constitute the staple element—the bone and brawn of the community. They are those, with few exceptions, commonly designated as cranks, the exceptions being, as a rule, clergymen of the nondescript variety; social agitators who have personal aims to advance and nothing to give away but bad advice (of which they give freely), and milk-and-water philanthropists who have not the back bone of a shrimp. This triumvirate and their followers make an army of no mean pro-

portions and one which is always in rebellion against the means that civilized society provides for its safety. The arguments of these social pests, which consist of sentiment, sedition and the froth of religious enthusiasm, are so loosely constructed that they go to pieces at the first fire of well-directed common sense. The criminal has sacrificed his all—his liberty, his life—to outraged public order, and the State for self-protection must curb his predatory and murderous instincts, but while doing so is at liberty to make the best use of him it can; therefore, his general health permitting, he should be made the subject of clinical investigation and experiment, forming the nucleus around which will gather the instructor with his class of freshmen and the very young junior who is on the threshold of his professional career. In this group, the central figure of which is the sick criminal, primary lessons in the art of healing will be recited and abnormalities pointed out and traced to first causes, even if a sentry with a bayonet is required to maintain order; this, however, will not be necessary when hard and fast rules are formulated and rigidly applied. There will, no doubt, be a wail, long and loud, from the world of crankdom before referred to, because of our cruelty to the criminal, whom they call a degenerate, whose murderous instincts are no fault of his, but some distant progenitor who bequeathed them to him, in thus singling him out as the object of attack for young doctors who are in search of experience; but the wail will be feeble compared to the thunder of approbation from hard-headed common-sense people. We make no mistake when we send the young physician to practise on the criminal, for, if a mistake in treatment brings fatal results, it is well that they occurred to him rather than to the honest sick pauper whose interests we consider only second to the man and brother who is now in his own ward reaping benefits to him new, though to which he was always entitled.

The fitness of things now is as apparent as the outrages are patent, so much so, that even the hospital governor with his well-known obtuseness and mental obliquity can see a light. The writer of this article does not think that misfortune and disease level and equalize social conditions, nor does he believe that even death renders void obligations that bind society together in a prosperous and orderly homogeneity of interests; for this reason he contends that people who have money and are willing to pay for a bed in a public hospital should not be thrust into a ward in companionship with a pauper; that the pauper has no right to share in their treatment, and, further, that the criminal pauper has sacrificed all rights other than what justice and humanity deem should be his. On this basis we have organized the hospital, arranged its wards and put a finger-board in Roman letters that all can see and read: "This Ward for Pay-Patients," "That Ward for Paupers" and "A Ward Downstairs for Criminals." Now, the patients are where they rightly belong and there is a place for everybody and everybody in his place.

The Training of Internes.—The blunders of the hospital internes are admitted by all physicians and surgeons to whom the writer has spoken on the subject (and he has spoken to many). They say, apologetically, "Haven't they to learn on somebody, and begin somewhere, and pray, tell us where such opportunities can be found if not in the wards of a hospital? We admit they make grave mistakes, and they would make such mistakes more numerous and pronounced were they not so closely watched by us." It is hardly necessary for me to say that the latter part of the sentence is to be taken in a purely Pickwickian sense, since it is a notorious fact that they are not watched at all. Lecturers and college professors make no secret of this, for now they can afford to be candid.

A quarter of a century ago it was the privilege of the writer to sit at the feet of a noted anatomist (long since dead) in the class-room of the College of Physicians and Surgeons, and hear from his own lips of the blunders that he made in his early interne days, while in the service of the celebrated Kerney Rogers at the old New York Hospital, Broadway and Pearl street. In performing an operation he forgot, or disregarded the warning of his chief, about a cardinal anatomical point, and cut into the gut in place of the peritoneum which he mistook for something else. At the recital of his blunder (for such a blunder was fatal in those days) his stalwart frame shook and rocked from the effort to restrain his emotions, so visible to the whole class. Then, with an effort he pulled himself together and said: "Boys, human life is too sacred for a student to run up against it with a knife; I am more careful now. Your motto should be, 'Make haste slowly.' Doubtless you have heard the lines, 'Fools rush in where angels fear to tread.'"

Under the present atrocious system, the moment the young doctor is let loose from the restraints of school (because he was more expert at memorizing than some less pretentious but sober-minded scholar, who doubtless will acquit himself well before the final race for professional honors is run) he is conducted to the ward of a hospital to treat haphazard or happy-go-lucky the patients quartered there. His less pretentious brother would not dare to take such a desperate leap for fear of killing the person on whom he might fall, besides injuring himself; he prefers to take an humbler position in the service of his preceptor and be guided by his maturer judgment; he is creeping cautiously into practice while the new interne is rushing on with cyclonic velocity, and as disastrous in his results as it. If this interne, who is so rapidly projected against the hospital ward, had the hardihood to enter private practice at this express-train speed, he would find himself suddenly derailed and landed in jail, where he might have to plead to manslaughter and probably face a

term of imprisonment. He will not be asked now to look in the face of a jury, or be put in the dock for lives that were jeopardized or sacrificed to the injudicious use of his knife, or his nonchalant diagnosis of acute alcoholism. Why? Because of the influences behind him, not the most insignificant of which are the iron gates and towering walls of the hospital, silent but potent defenders.

Then there is the old emeritus surgeon with his veteran brother—the attending physician—who is active yet. These two men live in the past now, but their memory is acute of days when both were internes inside the gray old walls of the hospital, which in age honors them for their fidelity to it.

Those old men, now landmarks, are proud of the internes; they see themselves of other days reflected through them. The interne is their heir apparent—the anointed one—and rail at him who has the assurance to question the right or ability of their protégé to do as he pleases with his own, his heritage, his patrimony—the patients in the wards of the hospital.

If the interne makes a slip, such influences, with the powerful aid of the trustees, shield him from the vengeance of the law. The same youth, the hero of so much disaster (not to himself understand, but to others who had to trust to his judgment, though his blood relations and intimate friends, who know him well, would not), because he was endorsed by agencies so powerful and men so influential, will, when the occasion and time present, leave the hospital without ceremony and immediately proclaim himself a member of a hospital graduates' club in a medical annual partly got up for this purpose. In this book he will announce to an astonished profession that by the present stupid hospital system he was permitted to perhaps acquire some knowledge of physic and surgery at the expense of those whom he treated. This he does in an artless but matter-of-fact way, and, being interrogated about it, says he did it because it is the custom.

Custom, it can be seen, is often cruel and does not by any means make right, and it should be the duty of a liberal profession like ours, aided by the best intelligence of the people, to see to it that right prevails. Gentlemen of this society, I tell you here now, as I told you on this platform a year ago this night, that if the people of New York could be made alive to the knowledge of the vicious and disastrous work done in its hospitals by beginners in the persons of imprudent juniors, who are permitted by the grace of the Medical Board and enthusiastically endorsed by the trustees, to masquerade as physicians and surgeons, it would speedily arrest their pernicious activity by putting a quietus on them.

Now, gentlemen, it should be the mission and business of us all to put a tongue in every vital wound their assurance and effrontery have made until the cry goes up: "Away with those insolent pretenders and destruction assail the system which permitted their atrocities to go unchallenged." Gentlemen of this society, I am no orator; if I were I would proclaim from the hustings and go into the market-place and the thoroughfare to awake the people to tell them of the wrongs committed in their name; nor am I a priest, gentlemen; nevertheless, I have heard voluntary confessions from hospital internes and graduates where the ghosts of their victims pursued them, making daily life intolerable from the lash and sting of remorseful conscience and night hideous by visions and ghastly dreams; where they went into other professions and perished by the wayside, dying of blight and dry-rot before the road to success came into view; how in their hour of travail they saw a light and heard a noise—fire from Heaven—it withered their souls; in it they recognized a voice: it was the anathema of one whom their juvenile efforts had consigned to the tomb, and who went in his early life unnoticed and unwept to a pauper's grave.

Preparation for Hospital Service.—The hospitals of this city can be classified generally under three heads, charity, public and private. The private hospital has reached a high degree of efficiency, for the reason that only two parties are concerned in its management—the owner, who is generally a surgeon, and the patient, who has something to say about what may contribute to her comfort. The private hospital has taken advantage of the mistakes in management and blunders in treatment in charity and general hospitals, and is conducted on lines more in consonance with the spirit of the times and demands of individual cases.

The charity hospitals are owned and under the exclusive control of the City and for the sole benefit of its sick poor; their services are as poor as are the people for whom they are intended, although the city is at great expense to maintain them and their various branches. There is probably no department of the city government where so much mismanagement and general inefficiency exist as in this department, but since a fierce light is now directed on it, and as it is otherwise the subject of investigation, the writer will refrain from any further comment at present.

The intemperate, the lazy and the shiftless poor are those, as a rule, found in the wards of a charity hospital. Some careless writers class this motley crowd of thriftless ne'er-do-well people as belonging to the working class, but they do not, and this is why they are so poor. The great stalwart army composing the working classes will not go to a charity hospital if they can help it, for before doing so they will exhaust every artifice and subterfuge known to them.

The public hospital, it appears, has a threefold function—a sort of trinity; it constitutes in itself three hospitals—charity, public and private—and in a sense it holds that all three are equal, as seen with the light of its eyes, and for this reason, all parties receive precisely the same

measure of professional treatment and social consideration, but this, however, is only in theory, for in practice it does not work and cannot while human nature remains what it is now. The failure of the general hospital to accomplish all that it should lies in this fact: It opens its doors to a poor man if he is endorsed at the office by a friend powerful enough to impress it; it takes all emergency cases and this it probably does to fill the requirements of its charter and make itself eligible for benefits by endowment or charity contributions. As things stand now, the private hospital is a success. The charity hospital could be made a success too, for the cause of its failure is lack of discipline and a general disposition on the part of some people to shirk duties they are poorly paid for performing. So much cannot, however, be said for the general hospital, because its basic principles and governing motive are vicious and ill-advised; matters of fact and propositions easy of demonstration; it brushes aside and straddles questions that admit of only one construction.

The charity hospital receives patients because they have no money and the private hospital rejects them on this plea—the one is taken because he has money, the other, because he has not. All this is very simple and contains no element of uncertainty. But the public hospital may take a patient and it may not; it depends on how full the wards are and the amount of influence the patient can command. The superintendent will tell you money is not a factor in admission: if the patient can afford it, well and good, if not, the hospital will stand the expense of maintaining him until death or convalescence ensues, always reserving to itself the right to transfer him to the charity hospital if conditions, in its opinion, warrant such a change.

In these two facts lie most of all that is vicious and inhuman in the management of general hospitals. It is not a fact that the hospital bears the expense of the man the superintendent took in yesterday; the expense of maintaining him is deducted from the week's board another patient paid, and who is his neighbor in the ward where both lie side by side. This is where the crying wrong of hospital management reaches a climax, and where the chicanery, if not stupidity, of the trustees becomes apparent, and this is why the writer of this article demands that the pay-patient be kept separate from paupers, and a proper classification be made of all patients received into the public hospitals. No more playing blind-man's-buff and trifling with the interests of an honest man, that a lazy man or a malefactor may be a beneficiary. The other crowning outrage and a monument to the atrocity or asininity of the hospital governor is the carting of a wretch in the throes of death to a charity hospital on some plea as flimsy as it is inexcusable. The governor took this man in as he thought in good faith, but he took him in only to cast him out at his pleasure, which act is the most arbitrary exercise of power we ever heard of, besides its gross inhumanity—an act for which the governor should be execrated and his name made a thing to mock at.

Under the present system, a young man with the ink not yet dry on his diploma can enter a public or a charity hospital and assume at a moment's notice a position of great responsibility, for at any time, day or night, the life of a senator, bishop, judge or truck-driver may rest in the hollow of his hand, as either one of the said parties or of us, gentlemen, may meet with an accident in the crowded thoroughfares, and without ceremony be hustled into an ambulance and helter-skelter, with break-neck speed, be pitched into a ward perhaps between a criminal and a pauper, or two criminals.

With the introduction of the new hospital system, the need of which has been pointed out, this cannot occur, for patients on entering will be assigned to their respective wards; appearances and the circumstances surrounding the injury will throw a light in consigning even an unknown man to a place appropriate for him. A conspicuous feature in the hospital reorganization is that the new interne will begin his work, not as an amateur, but one who has had quite some professional experience in the practice of his profession, for he has already served eighteen months in the charity hospital, rising gradually to the top from its graded course, and he is here now in the public hospital as the result of a successful competitive examination. He could not now get into the public hospital on any pretext whatever; he may have been clever in the classroom at recital and have influential family connections, but it won't avail if the fact is not established that he has been a graduate of medicine eighteen months, during which time he served in a city charity hospital, first in the criminal pauper ward, the pauper and lastly the pauper insane ward.

It is vital that the three divisions into which we have divided the public charity hospital, each be maintained perfect in itself and under the control of a physician and surgeon appointed by someone, not a politician, who then may be a judge of their fitness. The examination to be held for the fitness of applicants of eighteen months' experience in practice, and which is now admitted to be a good deal of a fake, exclusively gotten up in the interest of the college and for the ultimate benefit of its special students, should not be limited to graduates from any hospital, but must be open to bright lads practising under the observing eyes of their preceptors, who will now be preceptors in fact as well as in name.

There is no reason that the writer is aware of, why a young doctor who graduated honorably from a recognized medical school, and who has practised under an instructor eighteen months, cannot be a competitor before a medical board, half of which should consist of members of the medical profession outside of hospital and college circles.

The college and the hospital numerically com-

bined will hardly make fifty per cent. of the great army of general and special practitioners, yet they control all the patronage of the city hospitals and want more. Much friction has occurred from time to time among the profession from the fact that the college faculties wish to suggest or dictate who will or who will not be appointed to fill a vacant place on the staff of a hospital board of surgeons or physicians, particularly a charity one.

The Hospital Not Financially Affected by the New Order of Things.—The public hospital will not be materially affected financially nor will the number of its patients be reduced by the reorganization, as scores who are now dead-heads, resting comfortably in the wards, will pay willingly rather than be assigned to a charity ward—a thing and name hateful to them. The interne will now make his début in the ward of the new hospital as a more or less accomplished physician and as one who has seen service before, having passed through a graded course of careful instruction at the public charity hospital, or as one who has occupied his time since his graduation, working hard as an assistant to his preceptor or some other active practitioner, and he will have to work very hard in order to be able to compete for honors in the public hospital with the graduates from charity.

On entering the hospital the young doctor will again begin at the bottom, as he did eighteen months previous in charity, or as he did in the teeming tenement district under the tutelage of his preceptor, not at the top (as was the custom in old service days), and work his way up through the grades, which will be the same as in the primary school of instruction, with the exception that there shall be no criminal ward, only as far as emergency will supply, until transfer can be made convenient and easy. This plan will always leave a few criminals in the ward of a public hospital, but if only one remains, on him the interne must begin his professional labors, and those labors will extend from the criminal ward, through charity, up to the pay ward, which will be divided for the convenience of the insane into two parts, the senior one of which will be theirs.

The insane ward will be the goal of the hospital graduate's ambition, when, after six months' service in it he can, with good grace, make application to be mustered out of hospital service. To him, then, can be awarded some of the honors of a military hero, who is desirous of mingling with and bearing part of the civic burden of the people. The value of his three years' hospital service will now soon become apparent to himself, through an increasing and remunerative practice, to say nothing of the benefits conferred on the ward patients of all grades, from the wider knowledge and superior skill that he exercised as he gradually passed through successive wards, and the incalculable gain to the hospital in prestige for having prudent and efficient men to look after its affairs in the absence of the visiting staff, who will now feel assured that the interests of all are protected and advanced.

Pay for Physicians in Charity Service.—The professors and teachers in charity hospitals should be paid like those who do efficient and honest work in other channels of business industry. Why the city at present permits physicians and surgeons to toil in its charity hospitals unpaid is surprising and cannot be accounted for by the writer. There is no rule of law or equity to justify the city for its action in this matter. It cannot be claimed that a surgeon is bound to be more charitable than the clergyman who receives his yearly salary for ministering to his flock, or the lawyer who refuses to identify himself with a case without a retainer as a preliminary and inaugural step. It is no reflection on those gentlemen's integrity and sincerity of purpose (nor is it resented by the people in any way) that they look for pay for services rendered or to be rendered.

If a merchant, because he is rich, reduces the price of his goods to less than they cost him, he will benefit one man but ruin another. His neighbor who is not so rich will suffer from lack of patronage, while the merchant himself will soon become a pauper. The baker who sells bread for three cents a loaf will be patronized, while the other baker across the street who sells at the regular price, five cents a loaf, will be ruined; so will the men who furnish the latter with supplies. The generosity of the former is disastrous to the business interests of the latter, besides it ultimately destroys himself.

The physician who works for nothing for the city hospital or, for that matter, for any hospital, cannot by his generosity do any permanent good. True, he may render aid in a few isolated cases, but he is not doing the greatest good to the greatest number. The laws of business are definite and determined and fixed as any chemical law, and if violated, will bring punishment as certain as will the laws of nature, if their operations are tampered with or hedged about in any way. It is as much the duty of the municipality to care for its sick poor, as it is for it to properly police the city or build schools to instruct its children; but it does not expect the men who protect the city, nor the architects who design the school houses, much less the men who build them, to work for nothing. If those mechanics and artisans by a sudden impulse of generosity, like the baker, agree to render service to the city gratis for a year, who can be found to assert that the work will be as well done as if they receive a monthly check for labor performed? Not since Noah left the ark, and it is some time ago, was such a piece of cool impudence hurled at an astonished medical profession (and one which for cheek and effrontery will always stand alone) as the inquiry made recently into the methods of the Medical Board of Charity, who work for nothing, by a city official who draws a large salary. That official was aware

that this Board was performing professional services which were laborious and at the expense of its health and its pocket, to do a work of charity for a rich corporation, which is the city. To criticize its work is like looking a gift horse in the mouth, or for a tramp, to whom pity offers shelter for the night, to demand a spring bed, long-hair mattress and embroidered quilt, and beefsteak with mushrooms and green peas for supper, as a condition of acceptance.

The writer of this paper will say that the first step looking toward any permanent reform in hospital abuses will be taken when every attending physician and surgeon in every public hospital in the city is paid a yearly salary for services rendered. Only when this is done will any notice be taken or weight attached to the deliberations of a charity commissioner, no matter how worthy the motive that prompted his inquiry. No doubt it will be said in extenuation that physicians and surgeons proffer their services to the city, that they are knocking at the door of the charity commissioner, imploring him to permit them to aid him in the philanthropic work for which he is paid. Admitting this to be the case, which, to say the least, is an unfortunate condition, it is morally wrong for the city to accept the services so generously proffered by those professional gentlemen who are importuning the charity commissioner to permit them to work for nothing.

Not very long ago the writer was a witness at court, a civil court where the judge, a politician, with great impressiveness made the announcement in the middle of court proceedings that he was obliged to adjourn his court for the day in order to argue a case for a client in another tribunal. This was done in a crowded court-room to the consternation of litigants and to the detriment of business, for the civil functionary gave notice that he would not again open court until the following Thursday, though then only Tuesday at noon. Whoever heard of a physician or surgeon in or out of the city's service, or any other service, make such an announcement, or act in a manner so detrimental to the interests of the people? No one ever heard of a physician or surgeon, though working without pay for the city, do such an arbitrary act; indeed if he did, the charity commissioner would demand the reason why, and no reason that he could give would avert his summary dismissal from the service of the city. Yet, nobody asks the politician judge who received $6,000 a year to explain why he arrested the legal wheels of his court and put so many people to a serious inconvenience.

After knowing all this, and he must admit its truth, the Commissioner of Charity, with some indignation and great hauteur asks the Medical Board to explain, not of their own affairs, but of those of others over whose action they have no control. This mode of reasoning is fatal to the Commissioner, since it makes it apparent that it is he who should explain to the Board, and not the Board to him, since no other authority than his would be recognized by the delinquent and offending parties.

The City of New York pays surgeons and physicians for professional services with such reasoning as the preceding, though those services have as high a value as those rendered in any civil department, if not more, certainly as much as the District Attorney or Supreme Court Judge or the Register of the Borough of Kings, who, being an honest man, after deducting what he thought was a requisite salary from his yearly perquisites, amounting to $60,000, handed back to charity $50,000, a sum which his conscience would not permit him to appropriate to himself, being aware that physicians and surgeons are working for nothing, though rendering services as onerous and responsible as his own.

There might be some show of reason if some charitable organization asked free service from a physician, but none whatever from the city; it is not deserving of the slightest consideration from the medical profession, since it is conceded to be now, itself, a gigantic corporation, as soulless as the most exacting trust, demanding its pound of flesh and getting it every time. At present it has the power to levy taxes at its own valuation on every foot of ground within the city limits, but for appearance sake, at least, it reduces the tax a half or a quarter per cent., though in order to do this it very shrewdly raises valuations. Once the stamp of its approval is on a tax list it is as unalterable as fate. If a luckless citizen (even though he be a physician working for nothing for the city in one of its hospitals) fails to pay his taxes at the prescribed time, the interest is added to the principal after the manner of the most heartless pawnbroker, and this interest and principal must be paid, or compound interest with forfeiture of property be the result in the case.

Now, this is the moral standing of the corporation which permits physicians to work for nothing for it. Is it not the irony of fate, and does it not serve just right him who, while working for it for nothing, neglects his own business until his shanty is seized by the sheriff for nonpayment of taxes? The upshot of the whole matter is that one thing must be done and that thing is this—the City of Greater New York must be compelled by law to pay its employees for services rendered, whether those services be performed in the public park by a laborer, in the Supreme Court by a Judge or in the City Hospital by a physician. To hasten the time, the medical profession, shoulder to shoulder as one man, should make it its business, and put it on its calendar as the order of the day, to be presented at every monthly meeting, to ascertain the reason why members of its body—important ones—are expected, much less permitted, to render service for nothing while no such service is expected or would be accepted if proffered by either the District Attorney, a park laborer or a Supreme Court Judge.

If a physician or surgeon be disposed to work for nothing for a private or public hospital that is his business (but he will never be asked to work for nothing for the former) and not a wise one in the long run; but when a physician or surgeon is asked or permitted to accept a place on the visiting staff of the city hospital, it should be with the understanding that he will receive pay for his services. Every other employee does, why not he?

51 Charlton Street.

THE RELATION OF SUNSHINE TO THE PREVALENCE OF INFLUENZA.[1]

BY HOWARD S. ANDERS, A.M., M.D.,
OF PHILADELPHIA;
LECTURER AND CLINICAL INSTRUCTOR IN PHYSICAL DIAGNOSIS MEDICO-CHIRURGICAL COLLEGE; ATTENDING PHYSICIAN TO THE SAMARITAN HOSPITAL, PHILADELPHIA.

THINKING that there might be more elements and influences in the air and soil than were ever detected and demonstrated in connection with our etiology of influenza, I began, two years ago, a special and methodical study of the meteorological conditions just antecedent to, as well as associated with epidemics of this disease since 1895. The outcome was a preliminary paper (The Relation of Local Meteorologic Conditions to the Influenza Epidemic in Philadelphia, Winter of 1898-99) read before this Association and based upon a comparative analysis of the data for four years, for the months of October, November, December and January, the grip epidemic of 1898-99 having been at its height during the two months last named.

Introductory to the present observations it may be quite relevant to repeat here the tentative conclusions then reached, which were as follows: (1) Abnormal increase in the barometric pressure, and in the absolute range between the highest and lowest pressures for the epidemic months; (2) sudden, frequent and extreme alternations of abnormally high and low temperature ranges; (3) comparatively lower relative humidity during the prevalence of sharply epidemic influenza; (4) diminished precipitation, but short periods of unusual fogginess alternating with periods of dryness; (5) marked prevalence of strong northerly winds frequently alternating with very calm weather; (6) predominance of relatively clear and sunshiny days during exacerbations of influenzal attack; these attacking periods having invariably been preceded by sudden thaws and relatively warm, damp, muggy weather.

It was and is my purpose to complete these partial investigations and analyses by separate and seriatim studies of each meteorologic phenomenon and its relation to epidemic influenza; and to consider each phenomenon over a greater number of years, so as to afford a more reliable basis for more definite and decisive conclusions.

It is quite true, as Crawford[2] intimates, that practically nothing is known concerning the external conditions—meteorologic and telluric—that presumably favor the propagation of epidemics of influenza more violently and generally at one time than at another. The hope is cherished that in this series of researches something may be learned that may have somewhat of the prophylactic value to the public health that a storm signal has to those who sail in ships and cultivate our crops; or that a local weather forecast has to those who wish to go out of doors properly and prudently clad.

The relation between sunshine and the prevalence of influenza is studied first simply because suggested at this time by some observations made by J. Ruhemann, of Berlin.[3] It appeared that influenza was more prevalent when the amount of sunshine was less. In the eight years from 1893 to 1900 the number of hours of sunshine in Berlin during the month of January, when influenza was most prevalent, was between 9.8 in 1900 and 62.3 in 1899; the mean being 36.4 hours. Similarly, in Madgeburg from 1882 to 1900 the number of hours of sunshine varied during the same month between 19 in 1900 and 86.3 in 1883. A dozen other German cities and towns showed similar figures. More value might, however, be attached to these manifestly suggestive figures if they had been studied in relation to the mildness or severity of annual grip epidemics; if, as in the case of the Magdeburg observations, preceding years had also been noted for Berlin, before the 1889-90 pandemic; and if other influenzal months had been compared.

TABLE II.

	Hours of Possible Sunshine.	Hours of Daily Average Possible.
January	301.1÷31=	9.7
February	299.7÷28=	10.7
March	371.2÷31=	12.0
April	398.6÷30=	13.3
November	299.7÷30=	10.0
December	291.7÷31=	9.4

sunshine, as recorded for the epidemic months, should be compared with the daily average hours of sunshine possible for the respective months, so that the percentage of sunshine (Table I., 2d col.) may be derived. It is unfortunate for the most satisfactory comparative study that the exact instrumental registry of sunshine was not begun before January 1, 1891, in Philadelphia, thus omitting the important pandemic months of 1889-90, as well as preceding normal or merely sporadic years. The other tables, though less mathematically precise in construction, nevertheless compensate somewhat for this shortcoming in their more extended antecedent record—to and including the year 1880.

In the first place, it will be noticed that the sunshine percentages for all six of the usually epidemic influenzal months for the first three years after the great pandemic were uniformly low; and lower as compared with the total average for the years 1891-1901 inclusive.

But, on the other hand, beginning with the re-

TABLE V.—CLOUDY DAYS.

curring epidemic of 1893-94, the sunshine percentage shows a decided increase, except for the seasons of 1897-98 and 1898-99, during the former of which influenza was very moderately prevalent, while much more intense during the latter; and yet we have had influenza with us more or less every winter and early spring for the past eleven years, though the severity and sequelæ of the attacks may have diminished a little in some of the years.

On the whole, however, as compared with the possible hours of sunshine it will be seen that the daily average number of hours or percentage of sunshine is but a trifle over one-half for the months when influenza has been prevalent. Is this a normal condition? Or, does the group of an equal number of non-epidemic years preceding the last decade and more show a contrast to these data?

Observing Table III., we find that the total

number of clear days for the given months since 1880 up to the time of the pandemic of 1889-90 was decidedly less (by 68, see totals) than for an equal number of years since and including that mortal visitation. There were, however, 110 more cloudy days (see Table V.) for the epidemic than for the non-epidemic groups of years. At the same time, there were also 201 more partly-cloudy days (see Table IV.) for the ten years preceding than following the 1889-90 influenzal outburst.

In other words, a more moderate or average state of clearness or cloudiness—as one may choose to express it—prevailed before the "grip" attacked us so virulently; while the epidemic years have been characterized by an extremeness of these phenomena; indeed, the most rational conclusion justifiable from the facts and figures obtained is that non-equability of weather, as pointed out in my first paper, is a marked feature of influenza epidemic; and that a slight relative diminution of sunshine is associated with epidemic seasons. When one considers that less than one-third of the days were clear, and that the hours of sunshine are very few during the short days of the winter solstice, it seems not improbable that somehow *la grippe* likes the darkness better than the light. But it certainly is not inferable from these researches that there is the positive and direct causal relation between the absence of sunshine and *"die Intensität und Extensität der Grippe"* that Ruhemann would have us believe.

A CASE OF SUPPURATIVE OTITIS MEDIA FOLLOWING INFLUENZA; OPERATION WITHOUT OPENING OF THE ANTRUM; COMPLETE LACK OF ALL CONSTITUTIONAL SYMPTOMS OF INFLAMMATORY DISEASE.

BY O. WATERMAN, M.D.,
BERLIN, GERMANY.

THE case here described is of interest on account of the anomaly manifested in different points. First, because, while the entire mastoid process had been destroyed during the rapid course of the disease and while the insertion of the sternocleido muscle had been undermined, the bone surrounding the antrum and the antrum itself were found free from granulations and healthy. Under these circumstances it was not necessary to open the antrum according to the teaching of Koerner and Hessber, the latter of whom says in his book on "Suppurative Diseases of the Temporal Bone," "If after cleaning out the cavity a circumscribed maceration of the bone exists, which does not extend into the antrum, and where the bone in the immediate neighborhood of the antrum is found firm and not submerged by granulations, the penetration into the antrum is only necessary if pus still oozes from the cavum tympani and therefore suspicion of suppuration in the antrum exists."

Second, because notwithstanding the severe destruction of tissue the patient was free from all those symptoms which accompany severe inflammatory conditions.

E. F., female sixteen years old, came under my observation February 12, 1901. February 6th she had consulted a general practitioner for a severe pain in the right ear. He prescribed instillations of laudanum in olive oil and poultices. February 8th she noticed a discharge from the ear without, however, a diminution of the pain. She was then referred to me.

On examination, I found a perforation in the right drum, of moderate size, situated posteriorally and inferiorally, through which opening yellowish pus was freely discharged. The drum appeared red and around the perforation a few glistening, small, red granulations could be seen which reminded me of the "Zitzengranulationen" described by Politzer, Koerner and others. Temperature 98.8° F., pulse 78. Except for the still severe pain in the ear and an occasional headache, she does not complain.

She claims to have had a moderate cold a week ago in common with several other persons in the same family. At that time of the year influenza had been epidemic in Berlin and upon investigation the colds proved to have been attacks of la grippe, which was followed in one of the patients by a severe bronchopneumonia. At this time the mastoid process was a little painful on pressure; no swelling, however, could be seen.

Following the dictates of Teichmann, who says that in all cases of suppurative diseases of the middle ear following influenza we have to be extremely careful inasmuch as the ear complications which follow la grippe are very treacherous and that meningitis and brain abscess will frequently cause a fatal termination if in these cases mastoid complications are not quickly dealt with by surgical procedure, I determined, notwithstanding the lack of all serious symptoms, to have a careful eye on the case.

Syringing with boric-acid solution was ordered and cold application over the mastoid process. To enlarge the perforation was not found necessary. Soon the pain in the ear decreased, the discharge diminished and the sensitive area over the mastoid process was smaller. This treatment was continued until February 20th and during all this time the patient felt very well. Appetite and sleep were good. The functions of the body were regular. Temperature and pulse were never above the normal. Suddenly, on February 21st, the head could not be moved to the opposite side, the mastoid process was very painful on slightest touch and edematous. There also was pain along the entire right sternocleidomastoid muscle; discharge almost ceased. I ordered ice-bags over the mastoid process in intervals of two hours, to see whether any relief could be obtained, but, on failure to do so, the operation of opening the mastoid process was decided upon for the next day. The heart and lungs were examined and found healthy. The ophthalmoscope showed a normal papilla, but one temporal and one nasal vein appear slightly hyperemic. The

pulse that day reached at one time 104, which was evidently due to the excitement preceding the operation. It was the only day in which the pulse-rate exceeded 80. The temperature was normal.

Operation, February 22d. After the head had been shaved on the right side, the neck and shoulder were thoroughly cleansed and disinfected and then the neighboring region covered with sterilized towels. The incision through the skin, muscle and periosteum was T-shaped after the method of Faufal; the vertical incision 1 cm. behind the ear from the edge of the helix to the tip of the mastoid process; the horizontal incision vertically upon the former extending 3 cm. anteriorly and 4 cm. posteriorly and cutting through the temporal muscle. The copious hemorrhage was controlled by compressing the bleeding vessels with forceps and then the periosteum was elevated. It was found thickened and could be easily separated from the bone. The insertion of the sternocleido muscle was now severed and the external ear drawn forward with a sharp hook. Free inspection of the outer surface of the temporal bone from the linea temporalis and from the margin of the bony auditory canal to the lower edge of the mastoid process could now be obtained. The first stroke with the chisel brought away one teaspoonful of pus on very slight pressure. The undermined corticalis was removed in layers and beneath the entire mastoid process was found in a macerated condition, covered and interspersed with soft granulations, which extended very far back. The granulations were scraped with the sharp spoon, but it was found necessary to remove the processus *in toto*, as it was simply a mass of macerated bone, pus and granulations. The bone, however, in the immediate neighborhood of the antrum was hard and free from granulations and appeared healthy, so that it was thought best to leave the antrum undisturbed. Everything in the shape of bony fragments was carefully removed, the cavity wiped dry with sterilized gauze and the horizontal incision closed entirely by sutures. The vertical incision was closed to the lower angle of the wound, into which a strip of iodoform gauze was inserted to prevent adherence of the edges of the wound. The operation lasted one hour.

February 23d: Patient rested well; temperature 98.7° F.; pulse 82. The same condition was uninterruptedly observed until the first dressing was taken off. February 28th: The wound looks well. Very slight discharge from external meatus. The granulations around perforation of the membrana tympani are disappearing. Tympanum slightly reddish. March 6th: Second change of dressing. No secretion from the ear. The wound granulates splendidly, few granulations on the wound edges are touched with the lapis pencil. Appetite, sleep and general condition excellent. The wound was dressed every two days, healed very rapidly and twenty-six days after the operation only two scars, one linear and one depressed, bear evidence of the severe surgical procedure. Patient has gained nine pounds since the operation.

The hearing capacity of the right ear, which was almost *nil*, is now again as good as on the other side; watch heard 150 cm. What appears, however, most remarkable in this case is the disparity between the destructive process going on in the tissues and bone and the lack of all constitutional symptoms. If we consider that the extensive lymphatic plexuses, which are in the immediate neighborhood of the ear, favor the absorption of septic matter, it must certainly appear singular that fever and all other symptoms of inflammatory disease were entirely lacking in this case.

A CASE OF RAYNAUD'S DISEASE.[1]

BY W. A. HALEY, M.D.,
OF DURANT, INDIAN TERRITORY.

THE details of this case were as follows: I was called June 13, 1900, to see Mr. C., age fifty-five years. He was of good physique, had had rheumatism a few years ago in the knees and shoulders; this was of short duration and there was complete recovery; no history of syphilis. About May 15th he was taken with a burning pain in the two outer toes of the right foot. After a few days he called in his family physician, who pronounced the disease rheumatism and he was treated for that disease, without any improvement, until June 13th, when I was called to see him. I found him with a temperature of 100° F. The foot was cold and very painful, but not painful to the touch; there was, however, an intense burning pain inside. There was some anesthesia in the foot.

The parts had been thoroughly painted with tincture of iodine, therefore, I could not see the color of the skin on my first visit; but later could make out a cyanotic condition of the toes, foot and leg up to about the junction of the lower with the middle third. The pain seemed to come in paroxysms, at which times the cyanosis would be greatest and in the height of the attack he required morphine. At no time was he entirely free from pain. I noticed on about my second visit, which was on June 15th, that there were some blebs forming underneath and between the toes first affected. These progressed very rapidly and involved the anterior part of the sole and dorsum of the foot also. The cyanosis had extended almost to the knee by this time.

As the foot was involved in necrosis and the cyanosis reached almost to the knee, it was decided to amputate at the junction of the upper with the middle third of the leg. As the antirheumatic treatment had been thoroughly tried, I did not think it advisable to continue it further. Before an amputation was done the patient was given glonoin, hot fomentations to the affected parts, and every two to four hours the parts were painted with menthol dissolved in alcohol.

[1] Read before the Indian Territory Medical Association, June 5, 1901.

The hot applications gave some relief, but nothing stopped the progress of the disease, and, finally, on June 18th, an amputation was done at the point designated. The patient did well for the first twenty-four hours, at which time the intense burning pain manifested itself in the stump. The dressings were at once removed; there had been no effort on the part of Nature to unite the parts, instead the flaps were very white and cold, with now and then a cyanotic streak in the white. I then noticed that the femoral artery on that side had less than half the force and volume of its fellow on the opposite side; it required the closest examination to find it at all, while the other femoral could be made out easily, it being of normal force and volume.

It was decided to amputate again, this time in the thigh; as chloroform had been given before, ether was given this time. Everything was made ready, and with the usual precautions the anesthetic was commenced. Twice he became asphyxiated and at last the operation was given up, as the patient could not take chloroform or ether, chloroform having been tried lastly in the attempted second amputation. The whiteness in the stump rapidly gave place to cyanosis, and soon the necrotic process was going on in the stump as it was in the foot before the amputation.

It is needless to state that the usual aseptic and antiseptic precautions were taken in this amputation. After this the disease ran a rapid course; the cold and whiteness of the skin, followed by cyanosis, traveled up the thigh until the body was reached. Before death, which came on June 22d, a tingling sensation and numbness was felt in the hand of the same side. Death resulted from septic absorption from the gangrenous tissue necrosis in the leg and thigh. Temperature ran to 103° F. and 104° F. after sepsis began. Before that I had noticed that fever came only when the pain was very severe, but did not exceed 100° F.

The points to which I would like to call attention are that this disease is not confined to the young, nor is it devoid of fever, even before necrosis begins, as I have shown in this case. Neither is it necessarily a benign disease. Either from the intensity of the pain, or from some other cause, there resulted at times an elevation of temperature which is thought not to be in Raynaud's disease. There seemed to be an effort on the part of Nature to circumscribe the disease, as is noticed in erysipelas of the skin, not by a line of demarcation and a raised margin, but by a close blending of the normal with the pathological skin; but the process continued to involve new tissue.

The macroscopical examination of the affected limb within an hour after amputation, presented the following points of interest: The cut ends of the arteries and veins had lost but little blood. The skin maintained almost its original cyanotic appearance; the large vessels retaining their identity, while the smaller ones were lost in the tissues, which had every appearance of bruised tissue. I removed several blood clots from the long saphenous vein. I removed one some three or four inches in length; I did this by laying the vein open and lifting out the clot, it being well organized.

This affection is not similar to red neuralgia in that there was no local fever, the parts were cold, the cyanosis was preceded by whiteness of the skin, the arteries did not throb, but rather there seemed to be a constriction of the arteries; heat had some influence in relieving the intensity of the pain, cold made it worse.

THREE OBSTINATE CASES OF EMPYEMA OF THE MAXILLARY ANTRUM, CURED WITH INJECTIONS OF SOLUTIONS OF NARGOL.

BY A. G. WIPPERN, M.D.,
OF CHICAGO;
PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY, CHICAGO EYE, EAR, NOSE AND THROAT COLLEGE.

THE usefulness of the salts of silver in the treatment of disease has long been recognized, the nitrate being the one most generally employed. Unfortunately there are objections to the nitrate of silver, just as there are to many other excellent remedial agents. For example it coagulates the albumins of the tissues forming a protective covering over underlying structures. For the same reason its action is necessarily superficial in the treatment of purulent inflammations of mucous membranes. This is a peculiarly unfortunate circumstance, inasmuch as the germicidal and alterative effects of the drug are thereby limited to the surface of the membrane, while without penetration of the remedy into its structure the disease cannot be cured, although it may be held in abeyance for a period.

Another objection that prevails against silver nitrate is its well-known property of turning black in the presence of organic matter and under the actinic influence of light, thus causing indelible stains that may be a source of annoyance to physician and patient alike. From these facts it is evident that a silver salt which does not coagulate the albumins nor stain the tissues or clothing, is an improvement. Nargol, a compound of silver and nucleinic acid, is such a substance.

I have found nargol to be a very efficient germicide and alterative in the treatment of three obstinate cases of empyema of Highmore's antrum. After the persistent, though futile, use of ordinary methods of treatment, I was able to effect cures in these cases by means of injections of solutions of nargol having a strength of one-fourth of one per cent. As a report of these cases may be of interest, I append them.

Case I.—C. G., aged thirty-eight years, has had trouble in the right maxillary antrum for six years. The second bicuspid tooth had been extracted and communication with the antrum thus effected, but after five years' treatment, during which the patient wore a cannula, there was no improvement in the condition. He complained

of trifacial neuralgia and asthma, both of which distressed him at times to an extreme degree.

Last June, under chloroform anesthesia, I opened the antrum by way of the canine fossa, and after curetting the cavity packed it with iodoform gauze. At that time I found that the mucous membrane lining the sinus was but moderately thickened, and I concluded that the disease was probably secondary to nasal trouble. For a month the cavity was irrigated with solutions of boric acid, hydrozone, or permanganate of potassium, with little benefit; and although the attacks of neuralgia and asthma were not so severe, paroxysms frequently recurred. It was impossible to force the irrigating solutions through the ostium maxillare into the nasal cavity, whereupon a bulb-syringe was employed by which more force could be used; but even under great pressure, with ordinary solutions, the ostium was found to be impervious. A solution of silver nitrate, 0.25 per cent., was then injected three times weekly for a period of two weeks, with some improvement in the symptoms, although the osteum remained closed. At this stage of the case nargol was brought to my attention and, glad to try anything that held out the least prospect of benefit to my patient, I began to use it in 0.25-per-cent. solution, one quart of which was injected three times weekly. After the first pint had been used the fluid was observed dripping from the nostril. From that time I had no difficulty in forcing the solution through the antrum, and soon after the neuralgia and asthma disappeared. I discharged the patient, cured, after three months' treatment. During the past winter he was free from neuralgia and asthma, despite several "colds" and an attack of influenza. This case was an instructive one in many respects. For example, the gauze packing seemed to act as an irritant and the patient got along better without it, while the silver solution reduced the swelling of the mucous membrane and altered the nature of the discharge.

Case II.—Mrs. R., aged forty-three years, had an attack of influenza three years ago, since when she has had neuralgia. There was a purulent secretion from the nasopharynx, which was in all probability carried into the stomach during sleep, and to which the patient's impaired health was due. The woman had become emaciated and was conscious of a faint odor in the nose. At times she suffered terribly with toothache, to relieve which a number of teeth had been extracted, but without benefit. When I saw her the first time she declared that life was unbearable and that she would submit to any operation that might give her relief. Accordingly the antrum was opened through the canine fossa, and with a curette a large quantity of granulation tissue was removed, together with about half an ounce of yellow, cheesy material. At least a teacupful of blood was lost. After packing the antrum with gauze the anesthetic was discontinued. Two days thereafter the cavity was washed out and repacked; this was done three times weekly for a month, when it was found that the mucous membrane was so thickened that a second curettege was necessary. The cavity was now flushed out three times weekly for six weeks with a 0.25-per-cent. solution of nargol, and with the best results. After the lapse of four months there were no symptoms of the former condition and the patient was considered cured.

Case III.—Miss P., aged twenty-two years, attributes her case of antrum disease to a carious second bicuspid tooth. After it had been extracted and a cannula inserted, irrigations of the antrum with a saturated solution of boric acid were used three or four times weekly for two years with little improvement. The patient was troubled with a more or less profuse mucopurulent discharge, and neuralgia. She readily consented to have the antrum opened through the canine fossa, which was done and the cavity packed with iodoform gauze. Three days later injections of one pint of 0.25-per-cent. nargol solution were begun and continued daily for the first week, then three times weekly for a month. After two months' treatment of this kind the opening was allowed to close, the injections having been discontinued. Three months have now elapsed and this patient has made no complaint of any evidence of her former trouble.

In conclusion I would state that gauze is not needed to maintain a patulous opening in these cases so long as the cavity is irrigated three times a week.

TREATMENT OF TYPHOID FEVER.[1]

BY BASIL M. TAYLOR, M.D.,
OF GREENSBERG, KY.

ANY disease that has a duration of two or three weeks tests the skill of the physician. The patient has but one stomach and upon this organ falls the duty of absorbing medicine and of digesting the food necessary for the nourishment of the patient. Every organ in the body suffers from the effects of the toxins of the typhoid bacillus. The mind and the muscles can rest, but the stomach and heart must work or the struggle for existence soon ceases. These are the two organs on whose integrity the safety of the patient depends.

The treatment of any disease does not consist merely in getting a patient out of bed and discharging the case. This is only the foundation. There is more honor in keeping a man out of a fire than there is in dragging his charred remains from the flames. He is out of the fire, it is true; but he is not of much further service to his family. Nature with her fixed laws is the attorney for the patient and we are the judges to sit upon the case and allow no advantge to be taken by the ever-alert bacteria that inhabit and are constantly waiting for an opportunity to attack and devour the lowered vitality.

There is one rule to guide us in the treatment of diseases, namely, "Treat the patient and not

[1]Read at the Kentucky State Medical Society, Louisville, Ky., 1901.

the disease." Keep in touch with Nature and have a scientific reason for everything you do and say. Treat the case as Nature treats it and you will be Nature's assistant. The constant irritation of the delicate mucous membrane of the stomach by medicines for two or three weeks may change a once healthy stomach into a diseased one that may end the patient's life.

When we look over our records and see the number of lingering cases of typhoid fever, we may safely say that ninety per cent. of these cases could have been different if we had treated the patients skilfully. We may nurse and feed the patient faultlessly, loving hands may smoothe the pillow and make the bed easier, anxious friends may kindly remember; but one irritating and useless drug may defeat your plans and wreck the progress of the case. Then, whose is the fault? It is not the drugs; for pills and bullets are blind and wound friend and foe alike. You can claim the fault as your own.

As typhoid fever is a septic disease we must favor assimilation. No army can win a battle without ammunition. Toxins must pass out as rapidly as they are absorbed. The system has enough to do to eliminate the toxins from the fever alone without putting extra labor of eliminating undigested food and useless drugs.

The functions of the stomach are at least three fold, it digests, absorbs, and its juices are germicidal. The three work in harmony and to impair one impairs the others. Keep in perfect harmony with the trinity. To interfere, then, for a day with the functions of the stomach, places your patient in an extra hazardous position. We frown upon the surgeon who tries to cleanse his wound and at the same time dresses it with a foul dressing or one that favors the growth of an infecting germ. But we sometimes pat the doctor on the back and label him a hero who feeds and stimulates a patient every three hours for six weeks or two months and finally lets him up in spite of his efforts to the contrary. He heaves a sigh of relief and jests about how he pulled Mr. B. through such a severe case of typhoid fever. The bacillus of Eberth is selfish enough to claim all the praise and does not mention that the doctor was responsible for the extra sickness after they finished their contract.

When called to see a patient with typhoid fever, open the journal and examine his liabilities and assets. Is the patient older than his age? If so, why? Is his pulse excited, weak or strong? If so, why? Is he nauseated, full of aches and pains? If so, why? Is there gurgling in the right iliac fossa and is his tongue foul? If so, why? If there are these symptoms, be sure that you can wash your hands clean of their cause. There is no necessity for foul tongues, delirium, sick stomach, pains, headache, insomnia, high temperature, weak pulse in typhoid fever. If we will practise physiology instead of medicine we will avoid these. When you get a fever patient in bed give him a rest. I mean a rest from the crown of his head to the soles of his feet. There will be a drain on the system, a disturbance of the equilibrium between assimilation and waste. The patient lives on himself to a certain degree. Then we must minimize waste in every organ. The patient's mind must not be upon his business. If he has been irregular in his habits, we must at once establish a regularity, in fact, we must, as nearly as possible, reorganize his organic harmony and let each organ do its work.

Let us divide our cases into two classes: First, those who are healthy prior to the acute disease, and second, those who have had some chronic disease for years. In the first class we have an opportunity to show our skill, or *put* the patient into *the second class* for the next case of fever.

Case "A" is in the first class. He is a perfect type of physical manhood. He has been complaining for a few days and has called at the doctor's office several times for medicine. He was given calomel for biliousness and quinine for malaria. His already inflamed bowel is irritated by the calomel and his liver wonders why it is dosed and stirred up for a trouble that is ten or fifteen feet down the alimentary canal and over which it has no control. He grows worse and after a chill and a restless night with aches and pains he sends for the doctor. His liver, irritated by the calomel, has poured out a lot of bile and the patient has been vomiting it for several hours. The sight of so much "bile on his stomach" proves to the doctor that he is *very bilious* and that he must have more calomel. The calomel is repeated and so are the deleterious effects of the drug.

Now keep in harmony with the trinity. The patient has been taking medicine irritating to his stomach and has been eating indiscriminately since the first symptoms of his trouble, and the chill, high fever and headache tell us of the fact.

If the physician recognizes typhoid fever at once, he informs the nurse that he must begin to nourish and stimulate the patient to tide him over a long and dangerous illness. He directs the patient to take a glass of milk or a bowl of soup every three hours and if his pulse is a little accelerated from the toxemia, he mixtakes this for an indication for stimulants and directs him to take a tablespoonful of whisky every three hours until he returns.

A link in the trinity has already been broken and we make the separation greater and, perhaps, permanent, by our feeding and stimulation. A healthy stomach has enough to do to digest three meals a day, but when the stomach of Case "A" takes typhoid fever it needs a rest for the long task it has before it. It is made to work constantly by giving food every three hours. This is kept up for a week or more until the patient begins to vomit. Antiseptics and septics have been poured down day and night, disturbing the sleep so that if the patient dies, the family and the doctor can say that every thing was done for him that could be done! This is true in one sense of the word. No wonder it takes him weeks and months to recover.

The temperature is running to 104-105° F.; the

expression is dull; delirium is present; cordes are upon the teeth; the patient sleeps with coma vigil; the pulse is weak; there is diarrhea; there is gurgling in the right iliac fossa. The patient is now in that great state called the "typhoid state."

Each glass of milk gives impetus to the trouble. The milk passes into the bowels undigested and the patient poisons himself hourly.

Now about the whisky that has been given. Here I believe another mistake is made. Why? Because the pulse, laboring under the poison, is accelerated. You mistake this for weakness or an indication for stimulation. The heart needs a rest instead of stimulation. Stimulation causes overwork and exhaustion at the time when good circulation is most needed. Let the heart alone; it knows its own business better than we do. It is useless and disastrous to stimulate a weak heart-muscle.

Now for the treatment of Case "A." The best rule is, "If one don't know just what to give, *don't give anything.* Guess work in medicine is bad practice."

There already exists an inflammation in the bowels, and it is unsurgical to cause severe peristalsis by giving a purgative. Calomel is, then, unsurgical. If the patient is nauseated, I withdraw all food until his stomach is in a condition to digest it. Then I feed him three times a day and give just such food as he can digest perfectly. If the patient is not hungry at mealtime, I direct him to wait until he has an appetite. If his stomach is taken care of this waiting will not occur very often.

His food should consist of beef-teas, beefsteak scraped into a pulp and heated gently, crackers rolled fine, eggs either raw or cooked and soup in small quantities and highly nutritious. Orange or lemon juice will be grateful to the patient and will do no harm.

Never allow the patient to eat anything that requires mastication, but always prepare food so that it needs only to be mixed with the saliva. Thus the stomach will digest perfectly and the patient will be nourished.

When the temperature runs over 100° F. I use an antipyretic, antifebrine (about three doses during the day and one at bedtime), or a tepid bath for twenty or thirty minutes, will keep the temperature down and will make the patient more comfortable. I prefer the bath where it can be given. The patient is bathed two or three times a day with tepid water for about thirty minutes and the temperature will fall. If the patient is a little restless at night I give him a sedative. Bromides act nicely and leave no bad after-effect. As a rule, patients will rest well after a few nights if the nurse will not disturb them every few hours to give medicine and food. This is a point that I wish to emphasize—*Avoid disturbing a patient during his sleep.* Rest is essential to health and, of course, a patient needs it. Let him sleep until he awakes of his own accord. I permit the patient to drink all the water his stomach can absorb. It is next to impossible to give enough antiseptics to render the alimentary canal sterile; then, too, most antiseptics are gastric irritants and their continued use is dangerous. If there is much decomposition, I use small doses of some saline cathartic until the canal is cleansed and then I use tincture of iodine and carbolic acid in small doses until they are contra-indicated. Keep the mouth clean and let the patient chew tolu for a few minutes during the day. In my effort to guard the stomach I do not forget the colon and rectum. I irrigate the colon three times a day with warm water and if there is a catarrh, I use with the water an extract of pine and then at night inject into the sigmoid flexure Dr. J. M. Mathews'[1] prescription of almond oil, bismuth and iodoform. This will relieve the catarrh and prevent the lower bowels from absorbing the putrefactive material and thus helps to relieve the system of what plays an important part in the rôle of the typhoid state.

If water is not taken in sufficient quantities by the stomach, I inject about a quart into the colon and leave it for absorption.

Case "B." This class of cases to which Case "B" belongs gives us much trouble, because we begin the struggle at a disadvantage, but we have an opportunity to use the same care and judgment as in Case "A." I have had consumptives recover from typhoid fever as easily as robust patients, but dyspeptics are a source of worry. Digestion must be watched with special care. If there is myasthenia with fermentation, we must give a small amount of easily-digested food. The white of an egg given raw with pepsin and hydrochloric acid suits this class of patients. It is digested and leaves the stomach in about an hour and a half and this gives a much-needed rest to that organ.

Do not give milk to a patient with gastric catarrh or myasthenia. Milk given to the patient every three or four hours will, I believe, kill more patients than the fever. The colon is irrigated and the baths are used as detailed in Case "A."

In order to set forth my position more clearly concerning the stimulation and feeding only three times a day as being not as disastrous to my patient as may seem, I will give a brief statement of two typical cases, "A" and "B," which were treated in the manner described.

Case "A."—Male, married, age 24 years, previous health good. First visit, October 8th; temperature 102° F., pulse 90. He had been ill four days. He was nauseated and restless. Food was withheld for twelve hours. On the fourth day his temperature was 102° F., pulse 76. October 14th, temperature 100° F., pulse 80. October 31st, temperature 99° F., pulse 80. There was not a single stimulant given and his temperature and pulse were at no time during his illness as high as on the first day, being 102° F. and 90 respectively. He made a perfect recovery.

Case "B" female, age 24 years; had been nursing child for six months. She was very pale and

[1] Mathews: "Diseases of the Rectum."

anemic and had been too weak to do her housework. I saw her August 7th, she had been sick for four days with diarrhea and chills, headache and general malaise. Her temperature was 103° F., pulse 100. Her diarrhea was painful and was due to colitis. Her digestion was poor and she had no appetite. I used injection as described and fed her as her stomach would take food. On August 13th, her temperature was 101° F., pulse 100. Her diarrhea had ceased and she was gaining in strength. Her facial expression had cleared up and her appetite was good. August 23d the temperature was 100° F., pulse 116. August 27th, temperature 98° F., pulse 106. She was fed but three times a day and she was not stimulated at all. I am glad to say she did not starve to death, neither did her heart give up the fight for lack of stimulation. I gave her an opportunity to get well, and she took advantage of it.

In the treatment of our cases let the motto be, "Remember the stomach first, the colon next."

MEDICAL PROGRESS.

Alloxuric Excretion in Leucopenia.—The original conception was that the excretion of uric acid is increased in cases of leucocythemia. This was first pointed out by Ranke and subsequently confirmed by many other observers. In most of these cases, however, the uric acid estimations were obtained by the method of Heintz which has been shown to be far from accurate. Since the introduction of the more exact methods of Hopkins, Salkowski and Ludwig many cases have been examined from this point of view with the result that it has been shown that an increase in the number of leucocytes does necessarily involve a rise of the endogenous alloxuric bodies in the urine, but that only in cases of splenomedullary leucocythemia is a distinct increase of such bodies present. ROBERT HUTCHINSON and J. J. R. MACLEOD (*Jour. Exp. Med.*, Oct. 1, 1901) report a case of leucopenia which they have studied from this standpoint. The clinical symptoms were of an indefinite nature. The spleen was greatly enlarged while the liver was only slightly increased in size. The blood-count showed 4½ million red blood-cells; 65 per cent. hemoglobin and 1,500 to 2,000 leucocytes. The lymphocytes and polynuclears were about equal in number. No eosinophiles and no abnormal blood elements were seen. There were periods of pyrexia showing an evening temperature of 103° to 104° F. During the intervals of two or three days the temperature was normal. The diagnosis of Malta fever was made on the agglutination of the *m. melitensis* by a 1 to 30 dilution of the patient's serum. The amount of alloxuric nitrogen excreted in the urine was estimated each day during two periods of eight days each. Kjeldahl's method was used to estimate the total nitrogen excreted and the nitrogen of the total alloxuric bodies was calculated by Cramer's method. In the first period the total alloxuric nitrogen averaged about .17 gram in twenty-four hours, but on two occasions was a high as .22 gram and once as low as .122 gram. In the second period the average twenty-four-hour amount was .20 gram. These fall within the limits of physiological excretion which varies between .122 gram and .20 gram. The amount of phosphorus excreted was slightly above normal. They believe that in these cases the destruction of leucocytes occurs within the spleen rather than the bone-marrow and that the excretion of alloxuric nitrogen and the number of leucocytes are not parallel to each other.

Finsen's Light and the X-Rays.—The discussion on the treatment of lupus vulgaris and some other diseases of the skin by these new methods is fully and pertinently covered by MALCOM MORRIS (*Brit. Med. Jour.*, Sept. 28, 1901) who describes the new apparatus which has recently been installed in a special institution in the West End of London and states in what important details it differs from the somewhat cumbersome and very expensive outfit of Finsen. His source of light is electrical. Focus is of absolute import. If the disease be situated so as to interfere with its delicate adjustment the result is bound to be disappointing. Up to July, 1901, the total number of cases treated was 60. Of these, 36 were lupus vulgaris; 6, lupus erythematosus; 14, rodent ulcer; 2, alopecia areata; 1, keloid; 1, epithelioma. About 20 per cent. of the lupus cases were cured, the number of sittings varying from 8 to 370. In some of the more advanced lupus infections, particularly where there was marked scarring from previous old-time forms of treatment, or where the disease had involved the mucous membrane, as in the lachrymal canal and in all cases of rodent ulcer, the X-rays were used in conjunction with the light. The immediate result of the application of the light rays is of particularly import for prognostic purposes since the ultimate good seems to be in direct proportion to the intensity of the reaction. This consists in an acute inflammation which sometimes becomes very marked before the first treatment is over and which terminates in the formation of a bleb which breaks down and dries in about a week. In the neighborhood of the eye or, indeed, wherever the tissue is loose, this is often accompanied by very great swelling. The reaction is proportionate to the light and varies with the thickness of the skin and with its color, so that but little can be done with a negro. The Danes say that the treatment is painless, but this seems to be not always the case. It must not be supposed that the introduction of this new form of treatment precludes the use of the older remedies. In all the hypertrophic forms it has been noted that both the light and the X-ray could be greatly helped if the parts were primarily treated with salicylic or pyrogallic acid.

The prognosis depends, first, on the extent and situation of the lesion. Second, on whether it has had previous heroic treatment. Third, on the

patient's patience and ability to endure the daily hour exposures, and fourth, to his ability to continue the treatment, if necessary, from a year to eighteen months. As to the future of the light treatment, one may be confidently predicted for it, since, unconditionally, it is, as yet, the best treatment for lupus that we know. Its virtue in rodent ulcer is second only to that which it displays in lupus, an action which is particularly bewildering of explanation, since there are no germs at large awaiting destruction.

Agglutinines Obtained by the Use of Bacterial Cultures in Celloidin Capsules.—The relation of agglutinines to the bacteria producing them has been much discussed. The subject is of interest from the standpoint of agglutination to infection. At one time it was thought that the presence of the microbe in the tissues was essention to the production of these substances. JOHN MCCRAE (*Jour. Exp. Med.*, Oct. 1, 1901) has investigated the subject by inclosing bacterial cultures in celloidin capsules which were then inoculated intraperitoneally into rabbits. For this work he employed various species of paracolon bacilli. After a description of the method of making these capsules he concludes as follows: (1) Capsules of celloidin allow dialysis when placed in the peritoneal cavity; (2) the normal tissues unstimulated do not possess the power of producing agglutinines; they do not require the presence of the bacterial bodies, but will produce their share of the agglutinines when acted upon by bacillary products; (3) the production of agglutinines follows the insertion into the peritoneal cavity of "capsuled" bacilli; they gradually increase in amount and on the removal of the capsule containing the bacilli begin to disappear; (4) varieties of bacilli related closely in morphology and cultural reactions do not as a rule produce sera which interagglutinate.

Mouth Organisms of Infants.—Although the microbic flora normally present in the buccal cavity of adults has been extensively investigated, comparatively little if any research has been undertaken along these lines with respect to nursing infants. The subject is of importance in relation to the local and general pathological conditions often present. XAVIER LEWKOWICZ (*Archiv. de med. exp.*, Sept., 1901) reports the examination along this line of five infants. Three of these were healthy so far as known and one and a half hours, two and a half and eight days of age respectively. One three months of age was suffering from chronic enteritis. The fifth (three months of age) was dead of diphtheria, the material for examination having been collected twenty-four hours after death. His work comprised the employment of both aerobic and anaerobic methods. The bacterial find was greatly diversified. At birth the mouth is practically sterile. Very soon thereafter the streptococcus becomes the predominating organism. A non-pathogenic pneumococcus is also constantly found. In no case was the staphylococcus aureus present. Among the bacilli present the b. acidophilus predominated. As age advances anaerobic species make their appearance. Among these the b. bifidus communis and the streptococcus anaerobius micros. were the ones most often found. Anaerobes are able to live in the buccal cavity in the numerous furrows of the mucous membrane because of the presence of aerobic species. These materially reduce the amount of oxygen present in such location. The leptothrix buccalis was also found. In the cases of diphtheria and chronic enteritis the number of normal organisms present was not materially altered.

Congenital Dislocation of the Hip.—Tolerance of the body for sterile foreign substances in one place leads to trials in other places. In congenital dislocations of the hip O. WITZEL (*Centralbl. f. Chir.*, 1901, No. 40) has lately been trying the effect of gold-plated nails. His technic is to expose the trochanter through a small incision, after the dislocation has been so far as possible replaced and secured in plaster of Paris so that the foot points directly forward and the two limbs are of the same length. When the trochanter is in view the soft parts are bluntly separated until the head of the femur can be made out. Then over its upper margin are driven into the ischium five or six gold-plated nails, close together, beginning at the front and ending low on the back aspect. The nails serve the double purpose of a mechanical check to dislocation and of a stimulant to form a socket for the head.

Neutral Red Reaction for Detecting the Bacillus Coli Communis in Waters.—Some time since it was announced that the colon bacillus reduces solutions of neutral red, changing the color to a canary yellow, accompanied by a green fluorescence. This reaction was thought to be absolutely diagnostic of this microbe, until it was discovered that several anaerobic species (*b. tetani, b. anthracis symptomatici* and *b. œdematis maligni*) produce the same result. In bouillon, however, these species only give the reaction when oxygen is excluded. R. H. MAKGILL (*Jour. Hygiene*, Oct. 1, 1901) has investigated this subject from all standpoints and finds that the colon organism when grown in bouillon in the presence of neutral red always produces this reaction within forty-eight hours after inoculation. The test is very delicate, a reaction being given even in a dilution of one to five organisms per c.c. within twenty-four hours. He believes that this method is of great value in the examination of waters for the presence of the colon bacillus. A fair estimation of the number of organisms per c.c. present may also be obtained. A negative result may be taken as evidence of the absence of colon bacilli.

Treatment of Diabetes Mellitus.—In order that a prognosis may be safely ventured and the proper line of treatment instituted, R. F. WILLIAMSON (*Med. Chron.*, Aug., 1901) believes that three forms of this disease should be recognized, namely, the mildest form, in which the ex-

cretion of sugar disappears when a rigid diet is prescribed and the urine gives no reaction with perchloride of iron; the more severe form, in which rigid diet is not sufficient to stop the sugar excretion, but the urine still gives no reaction with perchloride of iron; and the most severe form, in which diet has but little influence and a dark brownish-red coloration appears when perchloride of iron is added to the urine. The weight of the patient should always be closely watched. In the first two forms treatment is usually begun by the use of a rigid diet excluding at first all carbohydrate food, but soon adding it gradually till sugar again appears in the urine. In the severe form, however, such treatment is dangerous, frequently causing diabetic coma and a rigid test diet is here contra-indicated. A valuable list of sanctioned and forbidden foods is also given. The forbidden animal foods are liver, oysters, lobsters, crabs, and mussels. Milk may be allowed in small quantities, but cream is an especially valuable article of diet. Nearly all the prepared antidiabetic breads and biscuits contain large quantities of carbohydrates and should be tested with tincture of iodine. The treatment by mineral waters at Carlsbad and elsewhere seems to have benefited some of the mild cases, but it is strongly contra-indicated in severe types of the disease. No drugs are required in the treatment of the early and mild cases. Opium and codeine seem beneficial in the less severe cases when combined with diet. Sodium salicylate, in ten-grain doses, three to five times a day, has given the author the best results of any drugs. Its efficacy is limited, however, almost entirely to the milder cases. In the most severe cases, especially when threatened with coma, sodium bicarbonate is strongly indicated. Even 900 grains have been given in twenty-four hours. Transfusion with alkaline fluids (sodium bicarbonate) has been known to relieve coma temporarily.

Somatic Signs of Brain Syphilis.—Fifty per cent. of all cases of brain syphilis are said to occur within three years after the primary sore. According to H. T. PATRICK (*Jour. Amer. Med. Assoc.*, Oct. 26, 1901) any brain case having an odd mixture of psychic and somatic disorder, a sequence of signs illogical as regards either time or localization, or a bizarre appearance, disappearance, reappearance, amelioration and aggravation of symptoms, should awaken suspicion of lues. The most important symptoms are the following: Headache, which is present in 75 per cent. of all cases, is notoriously nocturnal in its exacerbations, but may be vesperal or may even be most pronounced during the day; severity is the rule, and location unimportant. Transient attacks may occur, such as attacks of dizziness, syncope, momentary losses of consciousness exactly like petit mal, localized numbness or tingling, spasms of varying extent and intensity. Cranial nerve paralyses are frequent and striking, especially involving the nerves of the eye. The long course of the visual tracts, almost from pole to pole of the brain, makes them liable to injury by lesions of various location; hence alterations of the visual field occur frequently. Often syphilitic disease of the cerebral meninges spreads to the spinal membranes, producing symptoms of disease of the cord or its coverings. Associated with transient paralysis from the arterial disease which is usually present, there may occur general neurasthenic and myasthenic conditions, with insomnia or moderate somnolence, without focal signs. Aids to diagnosis in some early cases are increased deep reflexes and incoordination in finer movements. A somnolent, semi-stuporous condition occurs more frequently in cerebral lues than in any other brain disease. Fever is exceptional unless pons or medulla be involved. Vomiting is most likely to occur when the posterior fossa is invaded and when a large gumma or extensive meningitis is present. Polydipsia, polyuria and polyphagia are not unusual results of brain syphilis, nor is insomnia, which may occur aside from the inability to sleep on account of headaches.

The Suprarenal Capsules in Acute Infectious Conditions.—The lesions observed in the suprarenal capsules as the result of acute microbic infection have some time since been investigated by the means of experimental research. In diphtheritic, pneumobacillic, tetanic and anthracic infections the lesions of these organs are congestive and hemorrhagic in nature. Capsular rupture subsequently occurs in the majority of cases. Diphtheritic and pneumobacillic infections produce the most pronounced alterations in these organs. R. OPPENHEIM and M. LOEPER (*Archiv. de med. exp.*, Sept., 1901) have investigated this subject in man by the postmortem study of these organs in acute infectious conditions. They examined 16 cases of diphtheria, 10 of variola, 23 of lobar and bronchopneumonia, 5 of typhoid fever, 1 of tetanus and 4 of streptococcus infection. The postmortem study of the suprarenal capsules presents difficulties on account of the fact that ordinary initial changes following death greatly simulate those produced during life as the result of acute infections. As the result of such infections the glandular cells are profoundly altered. There is also hemorrhagic extravasation into the stroma in which the polynuclear neutrophilic leucocytes are especially abundant. True abscess formation occurs chiefly in the prolonged infections of variola and typhoid fever. No peculiar alterations were observed as the result of special infections and the changes in general were common to all the cases examined. A pericapsular sclerosis, cortical and central, was present in most cases. This chronic lesion is not due to the acute process, but is to be regarded as the result of previous repeated or continued infections. These investigators regard the suprarenal capsules as possessing an important function in the resistance of the organism to infection.

Bacteriological Status in Rheumatic Fever.—The view that the general medical public has accepted the truth of the microbic origin of rheumatic fever is held by Drs. E. J. POYNTON and

A. PAINE (*Brit. Med. Jour.*, Sept. 21, 1901). Still the presence of a specific organism can not explain all the problems in the disease. Such factors as the season of the year, heredity and exposure to cold must be taken into consideration. There are five views upon the bacteriology of the disease: (1) Rheumatic fever is the result of an infection with a diplococcus, according to Von Leyden, Triboulet, Dana, Apert, Wasserman and Malakoff, Fetz, Meyer and the authors. (2) Achalme and Thiroloux describe a large bacillus which is anaerobic and variable in its morphologic characteristics. (3) Rheumatic fever is not due to a specific organism, but it is a particular reaction to various infections. (4) Those simple uncomplicated cases which react to the salicylates are due to an unknown virus and the complications are the results of a secondary infection, usually with cocci. (5) Gustav Singer and others maintain that rheumatism owes its origin to staphylococcal or streptococcal infection, that it is, in fact, an attenuated pyemia due to pyogenic cocci. In conclusion the authors think that the idea the disease is due to a specific diplococcus has met with the greatest support. Also that it is safe to say that an advance has been made from the position that rheumatic infection is due to a bacterial infection, to the position that it is due to a diplococcus infection. Heredity is to be acounted for by a theory that the human tissue is in a condition favorable for the invasion of and the infection by the diplococcus. It is natural to hope that an antitoxin may be found. The discovery of the antitoxin may be a long and difficult task, though it is unwise to prophesy.

Hepatic Cirrhosis with Severe Anemia.—A case somewhat resembling Banti's splenomegaly with hepatic cirrhosis is described by E. HOKE (*Prager med. Woch.*, Oct. 3, 1901). The patient, a woman of fifty-three, complained of weakness, pains in the extremities, occasional vomiting, slight edema of the feet. Physical examination showed unusually pale mucous membranes, a pale skin of sub-icteric hue, cardiac dulness bilaterally increased, liver and spleen greatly enlarged to percussion, both palpable, but not sensitive. There was no ascites, and physical examination was otherwise negative. The blood contained between 800,000 and 2,000,000 red blood-cells, a normal number of leucocytes, hemoglobin about 20 per cent.; nucleated red cells were present at times. The urine was at first free from albumin, sugar, indican, acetone, diacetic acid, bile pigment; later, after febrile attacks, albumin and urobilin were found in the urine. The case differs from the so-called Banti's disease in several features, the latter being characterized by ascites, atrophy of the liver and very pronounced enlargement of the spleen, whereas in Hoke's case the liver was hypertrophied, the splenic enlargement less marked and ascites wanting. Bacteriological examination of the blood was without positive results.

Syphilis.—Several important questions were recently propounded to a number of noted syphilographers and their answers were published in full. L. A. DUHRING (*Inter. Med. Mag.*, Oct., 1901) urged the importance of recognizing that there are two forms of syphilis, the benign and malignant, and the course and treatment depend largely upon this point. G. F. LYDSTON believes that the physician should take no responsibility in determining whether a man should marry or not, but should acquaint the patient with the fact that the danger of infection diminishes with the years and is practically *nil* after four or five years. O. HORWITZ states that three years of active constitutional treatment are sufficient to produce a cure, but E. L. KEYES is more conservative and names five years as the limit within which marriage should be allowed. All agree that there has been little advance in recent years in the method of treatment and no valuable drug has been added to the therapeuticum armamentarium. In the management of the case, E. FULLER suggests that the diagnosis should be positive before treatment is begun and it is much better to delay treatment till after the secondary symptoms have arisen in any doubtful case. The patient's confidence must be obtained and the treatment followed most thoroughly and relentlessly after it has been once begun.

Tubercle Bacillus in the Diagnosis of Phthisis.—A correct understanding of the relation existing between phthisis and tubercle bacilli is highly important to medical men in the diagnosis of pulmonary diseases, says D. J. A. MATHER (*Brit. Med. Jour.*, Oct. 12, 1901). A patient presents himself with a history of cough, and mucopurulent expectoration; there is a rise of temperature and night-sweats. Examination shows an area of dulness, prolonged expiration, bronchial breathing and râles. Has the patient pulmonary tuberculosis, even though repeated examinations of the sputum fail to show the presence of the tubercle bacillus? Such cases in the author's opinion are not tuberculous because of the symptoms and physical signs. If the case is really tuberculous the bacillus will be found sooner or later. (1) The presence of the tubercle bacillus in the sputum proves conclusively the presence of pulmonary phthisis. (2) There are other agents besides the tubercle bacillus which can cause destruction of lung tissue and thus produce similar symptoms. (3) The absence of bacilli in a case of pulmonary disease does not rule out tuberculosis. (4) It may be due to (*a*) simple phthisis, (*b*) faulty methods of examination of the sputum, (*c*) very early tuberculosis in the lung, (*d*) very little tuberculosis where signs of fibrosis are evident. (5) The case is hard to diagnose correctly without the bacillus after frequent examinations, especially where the history, signs and symptoms should be relied upon more than the negative evidence. (6) In all cases of pulmonary disease, a systematic examination of the sputum is of the utmost importance both for negative and positive evidence of bacilli.

Arteriosclerosis.—Too little importance is

generally attached to the functions of the arterial system, for conduction of blood is by no means its most important one. The mechanical functions of contraction and dilatation and the living functions of oxygenation, nutrition and, in short, metabolism belong to this system. C. E. NAMMACK (*Med. Rec.*, Oct. 26, 1901) in discussing this condition points to its important relation to the medical profession, whose members usually grow old rapidly because the strain of life brings on an early arteriosclerosis. The causes may be considered under the headings of heredity, age, sex, alcohol, syphilis, gout, infectious diseases, high living and hard work. The death-rate of medical men in New York and Brooklyn from 1884 to 1892 was exceeded only by that of saloonkeepers, butchers, quarrymen and underpaid factory operatives. Thirty-five per cent. of these died from the threefold sequelæ of arteriosclerosis, that is, from Bright's disease, apoplexy and heart disease.

Rheumatic Nodes in Children.—Among 75 cases of rheumatic nodes published in recent years fully four-fifths relate to patients over twenty years of age. Rarely are nodes found after a first attack of rheumatism, as in a case reported by A. JOSIAS (*La Méd. Moderne,* Sept. 25, 1901). The subject in this instance was eleven years old and was suffering from a polyarticular rheumatic attack. The nodes were situated beneath the skin, which was freely movable over them and normal in color; they seemed to be adherent to the deep tendons and in some instances to the fibrous tissue covering the bones. In size they varied from that of a hempseed to that of a lentil. They were found on the hands, about the wrists, elbows, shoulders, feet, ankles, knees and head. The patient was kept under observation during a period of two months, during which time most of the nodes disappeared while those which remained diminished in size. One of the nodes was removed for examination and was found to consist of a flabby tissue which histologically revealed a vascular network with thick walls. In cases previously reported nodes were formed of fibrous tissue and sometimes of cartilage; others are said to have had necrotic areas. Nepoen is said to have found bacilli and micrococci in the lesions; bacteriological examination by Josias was negative. The latter compares the rheumatic node to the endocardial vegetations of rheumatism; in both cases there is a cellular proliferation superinduced by the same infectious cause. Endocardial growths may occur without accompaniment of subcutaneous nodes, but the latter are always accompanied by endocardial lesions and usually by choreic symptoms as well.

Inorganic Salts and Organic Crystalline Substances and Agglutination.—Until very recently agglutinines have been considered the only necessary factors for the production of natural agglutination. Artificial agglutination may, of course, be produced by many other agents. Latterly it has been ascertained that agglutinines are non-effective for the production of this phenomenon unless accompanied by certain other substances. E. FRIEDBERGER (*C'tlblt. f. Bak.*, Sept. 16, 1901) has investigated the relation of various inorganic salts and certain organic crystalline substances to this process. His studies were limited to the cholera and typhoid organisms. For agglutinating purposes he employed two sets of specific sera. The first had been recently obtained from goats, while the second had been under preservation for some years. All salts were removed from the bacterial cultures and sera by dialysis. The inorganic substances investigated were the various salts of sodium, barium, calcium, potassium, magnesium and ammonium; the organic included among others asparagin, glucose and urea. The result of his work shows that agglutination does not take place in the entire absence of crystalline substances from the suspension fluid. Inorganic substances vary in their importance in this respect, but taken collectively are more necessary than the organic. The rapidity of the agglutination of dialyzed cultures is dependent upon the proportion of sodium chloride present in the suspension fluid. The mode of action of these substances is not chemical.

Ocular Affections of Childhood and General Malnutrition.—Besides the ocular inflammations, such as blepharitis ciliaris, styes, phlyctenular conjunctivitis, ulcers of the cornea and affections of the lacrimal apparatus, occurring in strumous or rickety children, there is a group of ocular affections in which the local conditions are not so obvious as to drive the parents to seek advice. In a typical case described by S. D. RISLEY (*Phil. Med. Jour.*, Oct. 19, 1901), a boy of twelve, who had been previously treated for hypermetropic astigmatism, was brought back complaining of severe headache and petit chorea. The child had developed an ungovernable temper, had lost a previously lively interest in school work and was regarded with aversion by his associates. Study of the eyes revealed a change from farsighted to nearsighted astigmatism, accounted for by stretching of the eyeballs. There were notable changes in the fundus, especially granular changes in the macular region of both eyes and beginning absorption areas. The child's breath was offensive, he had hypertrophied tonsils and intermittent albuminuria. Under correction of the changed refractive error, regulation of diet, outdoor life and tonic medication the boy resumed his original healthy condition and his symptoms entirely disappeared. In these cases there are usually general and ocular symptoms. Headache, general malaise, precarious appetite and variable temper, are accompanied by undue sensitiveness to light, inability to read with comfort, impaired acuity of vision, injected lid borders and conjunctiva, impaired nutrition of the globe with distention of its coats and resulting increasing refraction. The existence of a congenital hypermetropic astigmatism with faulty metabolism favors the development of pathological states which cause the distention.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

THE EXORCISM.

Now that the swine are about to rush violently down the steep hill of disappointment and be for a time submerged in a sea of reform, the pearl merchants may safely offer their wares to the public.

Sentiments of order, cleanliness, decency, and morality will not be trampled into the mire, but will have a permanent setting in the streets and homes of this city.

For the past two years New York has looked like a house without a housekeeper; it has been a disorderly, badly kept, extravagantly managed and dirty dwelling for its millions of inhabitants. Its rulers have protected filth, immorality and crime. They have shielded lawlessness, prostitution, drunkenness and corruption. But that day is past.

We knew what it was like to have a clean city, under the scrupulous care of the late Col. Waring, who glorified drudgery by doing his task perfectly; and we hope to be clean once more. We knew what it was to have an energetic, efficient Board of Health in the days of Mayor Strong's administration, when there was no iron hand to retard progressive work and no underlying network of politics to tangle the feet of those who went too deeply into questions of reform.

Physicians of this city are hoping for several things for which they have preached and prayed. They expect to see a renaissance of the former splendid work of the Board of Health, work that made New York's methods prominent at home and abroad, but which has recently all but had its life teased out by Tammany.

They expect to see Bellevue reorganized, and all possibility of scandal forever removed by the establishment of the City's hospital service on a system that cannot be affected by politics. They hope to see the tenement-house problem, which is almost an equivalent of the problem of tuberculosis, treated from the standpoint of humanity and sanitation. They hope to see the question of prostitution and venereal disease dealt with sensibly and soundly, for this is the type of reform that can see further than vice, and that will heed the counsels of the profession which has for years been trying to teach the public somewhat concerning the aftermath of vice.

It is worth while to be alive in New York at the present time; to think, to act, to counsel, to work for the good health of its citizens; and many an able man in our profession, who has been compelled to shut his eyes to conditions that he has been powerless to control, will rejoice that he is permitted to open them wide and point out to his fellow citizens the foci of infection and the overwhelming possibilities for the spread of disease in the existing conditions of things; and—have them remedied.

THE VAGUS AND ITS NEWER PHYSIOLOGY.

WHEN it was announced a short time ago that the Nobel Prize for the greatest advances in medicine in recent years had been divided between Prof. Finsen of Copenhagen and Prof. Pavlov of St. Petersburg, most of the Western medical world wondered. Prof. Finsen many had heard of, but very few physicians are familiar with the name of Pavlov or with his work. It is true he was selected as one of the world's representative medical men, who like Virchow and Albert and Burdon Sanderson and our own Jacobi, were chosen to address one of the general sessions of the last International Medical Congress, but even this failed to give him more than passing notoriety. His address in Paris, read in his absence by his assistant, contained some of the most striking results of his original work. Its general tenor was, however, a review of experimental physiology in the century just closing, so that the

conclusions from Prof. Pavlov's personal observations escaped special notice.

The most striking bit of original work that the distinguished Russian physiologist has accomplished is the keeping alive for an indefinite length of time after the primary operations of animals in which both vagi nerves were cut. This, until Prof. Pavlov's observations proved the contrary, has been deemed impossible. Vagotomized animals died in a sort of cachexia within a few weeks after the section of the second vagus. Schiff and Traube, about the middle of the last century, disputed as to whether death in these animals was due to trophic changes in the lungs and systemic disturbances consequent upon the lowered activity of respiration, or to deglutition pneumonia, because the interference with the sensory nerves to the larynx allowed foreign bodies to find their way into the lungs much more easily than before. Prof. Pavlov's work has opened up an entire new field, and in this day of highstrung nervous tension is most suggestive of the influence of nervous force even in the cruder processes of digestion and absorption that are so often assumed to be merely chemical or physical in character.

The now distinguished Russian investigator showed that vagotomized animals really perished because of disturbance of their digestive functions. If they were fed entirely through a gastric fistula, the upper part of the esophagus being completely closed so as to prevent regurgitation of food that might find its way into the lungs through an insensitive larynx, then the animals could be kept alive indefinitely if their food was of bland, unirritating character, and if their stomachs were washed out whenever fermentative processes caused digestive disturbance. Without these precautions the animals invariably perished with the well-known cachexia. This cachectic condition Prof. Pavlov found to be really due to a form of digestive autotoxemia besides inanition from the failure to find food in the digestive tract properly prepared for absorption. In every way the vital functions of the gastro-intestinal system were lowered by section of the vagi. Purgatives, for instance, which in normal animals produced only slight effects, in vagotomized animals gave rise to serious persistent diarrheic conditions that finally led to a fatal termination. An ordinary dose of calomel is fatal to a vagotomized animal.

The vital condition of all organs to which the vagus is distributed is distinctly impaired after vagus section. As was known before, respiration becomes much slower and even internal respiratory processes are interfered with. The supposed trophic influence of the vagus upon the lungs is denied. Animals kept alive for months after vagus section show at autopsy no trophic changes in the lungs. This is an interesting commentary on some recent therapeutic work in tuberculosis done here in America, the basic theory of which assumes that the vagi are pulmonary trophic nerves. The supposed trophic action of the vagus upon the heart muscle is also denied. At autopsy on vagotomized animals no degenerative changes in the heart muscle are found. The heart suffers as the result of digestive disturbance, but otherwise is normal.

The most interesting effect of vagus section is that produced upon the systemic heat regulation. The internal temperature of animals is usually very constant. After section of the vagi it is liable to frequent variations for very slight causes. A little exercise causes the temperature to go up 2.5° F. Exercise for a couple of hours may cause a variation of 4 to 6° F. After exercise the vagotomized animal must be watched carefully and treated by cold douches in order to prevent serious or even fatal results from overheating. Variations in the temperature of the air in which the animal is kept produce serious changes in the animal temperature. When the air rises to 85° F. the vagotomized animal responds by a distinctly febrile temperature. These animals are affected in a like unfavorable way by cold and succumb rapidly to temperatures that they were able to bear with impunity before the operation.

In a word, much of that elusive quality we know as vital resistance in tissues and on which so much depends as regards infection with disease material, or convalescence, after serious illness, is dependent on the impulses that travel down the vagus nerves, finding uninterrupted paths to the important organs. We have been accustomed to attribute much of this normal vigor to the circulation of the blood. Undoubtedly the blood has much to do with it, but the other factor of nerve force must also be taken into account. It would seem that somehow that principle of activity we call life is more especially present in the central nervous system and from here vital force finds its way to the subsidiary tissues. These ideas involve the assumption of certain theories with regard to vital force that have appeared antiquated, but are recalled to prominence by scientific advances. Their importance for the

practitioner lies in the lesson they teach that mental states are important in therapeutics and that medication may well be almost hopelessly hampered where serious disturbance of the central nervous system is brought on by emotion or worry. Mental influences have long been recognized as factors in therapeutics. These later advances in nervous physiology help to make clearer than before what are the physical bases for such hitherto obscure influences.

THE ART OF PRESCRIBING.

THE practice of writing an order for a particular form of a compressed drug or for a proprietary medicine is growing upon physicians, and bids fair to keep pace with the vast output of these skilfully advertised preparations.

The effect of this tendency is detrimental in many ways. No matter how convenient and suitable that particular proprietary form may be for the individual case, the readiness with which it may be obtained at the drug-store leads patients to recommend it to their friends who are suffering from what they imagine to be similar complaints. If the drug be an anodyne, it leads the patient into the often fatal mistake of thinking that to relieve pain is the end of medical science, and while he himself relieves his own pains allows the cause of the trouble to get beyond control. The habit of taking narcotic drugs is gaining from this very cause, that physicians simply write the name of a preparation containing them, which can be repeated without question from the pharmacist. It is surprising to see how the compressed forms of powerful drugs have in the last twenty years taken the place of the simple and often innocuous household remedies. People keep nowadays in their medicine chests and carry about in their pockets powerful doses of phenacetin, antifebrin, antipyrin, atropine, codeine, etc., which they take according to their own discretion, and prescribe generously for their friends.

The evil is by no means one of American enterprise, if we may judge from the address that Dr. Arthur P. Luff of London delivered before St. Mary's Hospital Medical Society of that city, and published in the *Lancet* of October 26th. His topic is "The Decline in the Art of Prescribing," and he takes the stand that in this era of brilliant discoveries in medicine, pathology and bacteriology, there is a tendency to neglect the treatment of the common minor ailments by drugs. He holds that one of the main reasons for the decline of the art of prescribing is the inadequate attention given to the subject by the members of the staff of the various teaching hospitals. This is undoubtedly due to overpressure of work, especially in the out-patient departments, where the use of a hospital name for a ready-made formula becomes a time-saving habit. These formulæ the student is supposed to look up, but as a matter of fact he does not; and the consequence is that, from force of habit, in his own practice he tends to use some convenient ready-to-hand preparation instead of working out a prescription suited to his patients' particular need.

He maintains that there "is no better way of acquiring a knowledge of correct dosage, and of avoiding the incompatible ingredients, than by hearing the physician or surgeon dictate his prescription, comment on the dosage of the ingredients, and give his reason for the employment of such ingredients." He holds the formal systematic lecturers of the medical schools somewhat to blame for the lack of time allotted to the students for the practical experience in diagnosis and treatment of disease.

Most earnestly does he beg the student of the day to cultivate by every means the knowledge of the art of prescribing, and never to become the instruments by which patients may be tempted to drift into the habit of self-treatment by compressed and other easily administered drugs.

To all of which we say *"Amen."*

LABORATORY DIAGNOSIS OF TYPHOID FEVER.

THE differentiation between typhoid fever and simulating conditions is one of the most frequent problems which presents itself for solution. While in a fair proportion of cases the clinical symptoms alone suffice for a correct appreciation of the condition the wide range in the symptomatology of this disease often renders the sure diagnosis by such means impossible. Particularly is this the case during the first days or weeks before characteristic symptoms have developed.

During the past few years much attention has been given to the laboratory diagnosis of this disease, with the result that several methods for such diagnosis have come into use. An impartial consideration of them will lead to a correct appreciation of their worth and a clear understanding of their application. They may be considered under three heads: (1) Blood exami-

nations including leucocyte counts and the Widal reaction; (2) the diazo reaction of Ehrlich; (3) isolation of the typhoid bacillus from feces and urine. The fact that the total number of leucocytes is materially decreased in typhoid infection has been long established. Somewhat more recently attention has been drawn to the marked reduction of the polynuclearneutrophile granules, which is in most cases established early in the disease, often in the first days, and to the fact that at this time the large mononuclear leucocytes are increased in number, so that the total leucocyte count may remain nearly normal. This quantitative relation of the leucocytes seems to be a characteristic of pure typhoid infection and, as far as is known at the present time, it does not occur in infection with any other organism save perhaps the bacillus tuberculosis. As we rarely meet with a pure tuberculous infection in man, except in acute miliary tuberculosis, its value as a means of diagnosing typhoid infection is great, especially in the first days, before other laboratory factors have been established.

The value of the Widal reaction has been much discussed and with the profession at large it has fallen somewhat into disrepute. This, we believe, is due to the inaccurate manner in which the test has been conducted and to the lack of appreciation of the limitations within which its clinical value exists. It should be remembered that the failure to elicit the reaction in a given case in no way negatives a diagnosis of typhoid, unless a number of such tests covering a considerable period of the disease have been made. Also that its diagnostic value essentially consists in the degree of dilution of the serum employed and that only positive deductions can be drawn when this dilution is high. It should also be noted that its value stands in direct relation to the duration of the disease, the further advanced the condition the greater being the liability of eliciting a positive reaction. It is, therefore, in the latter weeks of the disease that its maximum value exists.

The diazo reaction of Ehrlich, which a few years since was regarded as of great value, is now seldom employed, as it occurs in altogether too many other conditions which closely simulate in symptomatology typhoid infection. Its value may be regarded as supplementary to a slightly pronounced characteristic leucocyte-count or a positive Widal with a low dilution.

The isolation of the typhoid bacillus from feces or urine is the most absolute way of diagnosing the condition. When the methods for such have been placed in competent hands and have been employed at a proper time during the course of the disease results have been obtained which exceed in value those given by any other method. Unfortunately, however, with the present knowledge this method is seldom available in the first week. From this time on it is the method *par excellence* to be followed provided those who conduct the test have had extensive experience along this line. From a consideration of these methods it is seen that there is no one of them which is available for diagnostic purposes at all times and under all conditions during the course of typhoid fever. It is evident, therefore, that those who would obtain the best results must not be limited to any one method, but must employ that which possesses the greatest value for the particular stage of the disease.

ECHOES AND NEWS.

NEW YORK.

New York Academy of Medicine.—At the last general meeting of the Academy Dr. M. Allen Starr read a paper on "The Causation of Multiple Neuritis," which was ably discussed by Drs. Dana, Sachs, Peterson and others This paper will appear in a subsequent number of the MEDICAL NEWS.

The following candidates were recommended for resident fellowship in the Academy: Drs. P. F. Adams, S. W. Bandler, S. V. Haas, G. D. Hamlin, J. A. Hartwell, L M. Hurd, T. C. Janeway, J. M. Mills, and H. Smith; for non-resident fellowship the following were recommended: Drs. H. C. Neer of Park Ridge, N. J., and J. M. Rector of Jersey City, N. J.

On Monday, November 11th, Dr. B. T. Tilton will read a paper before the Section on Surgery on "Etiology of Unusual Forms of Peritonitis."

On Wednesday, November 13th, the Section on Otology will meet. Dr. Arnold Knapp will read a paper on "A Case of Meningitis from Extension of Acute Purulent Otitis Media through the Aqueduct of the Vestibule."

On Thursday, November 14th, the Pediatric Section will have presented a new automatic siphon for separating cream or top milk by Dr. H. L. Coit, and Dr. Milton A. Gershel will read a paper on "The Value of the Widal Reaction in Children," and Dr. David Bovaird, Jr., a paper on "Primary Intestinal Tuberculosis in Children."

The Section on Orthopedics will meet Friday evening, November 15th. Dr. Homer Gibney will read a paper on "Orthopedic Operations for Intractable Cerebrospinal Cord Lesions" and Dr.

Henry Ling Taylor a paper on "The Effect of Osteitis of the Knee on the Growth of the Limb."

Inhalatorium Man Charged with Practising Medicine Illegally.—Dr. F. Elbert Davis, who says he is the junior partner in a company which conducts an establishment called the "New York Inhalatorium" in the Astor Court Building, was arrested last week, charged with practising medicine without being registered. A warrant had been issued for his arrest on the complaint of Daniel Getz, of 212 East Seventy-Seventh Street, an agent of the County Medical Society.

A Group of Portraits.—About a year ago, within the short period of three weeks, four eminent and distinguished physicians died. Two of these well-known men (Hunter McGuire and Lewis A. Sayre) were surgeons, two (Jacob M. DaCosta and Alfred L. Stillé) were physicians, and three of them were ex-Presidents of the American Medical Association. The Arlington Chemical Company has commissioned a competent artist to paint them in oil in the shape of a panel suitable for framing, and have reproduced the painting for distribution to the profession. This group of portraits is now ready and a request will bring a copy.

New York Skin and Cancer Hospital.—The governors of the New York Skin and Cancer Hospital announce that Dr. L. Duncan Bulkley will give a fourth series of clinical lectures on diseases of the skin in the Out-Patient Hall of the Hospital on Wednesday afternoons, commencing November 6, 1901, at 4.15 o'clock. The course will be free to the medical profession.

PHILADELPHIA.

Polyclinic Hospital and School for Graduates.—Dr. John H. Gibbon has been elected professor of surgery. He succeeds Dr. T. S. K. Morton, who was made emeritus professor. Drs. S. McC. Hamill and James H. McKee have been elected professors of diseases of children.

Disinfection of Street Cars.—President Parsons, of the Union Traction Company, has notified the Bureau of Health that all cars of the Company are nightly disinfected by washing them with carbolic acid solution. The odor thus caused is noticeable in the cars, but in view of the presence of smallpox in the city patrons do not complain. New cases of smallpox still grow less in number, but the death-rate is increasing, last week showing seven less cases and two more deaths than the preceding week.

First Aid for Injured Miners.—A State law which interests every miner in the anthracite coal regions went into effect November 1st. It provides that at each colliery there shall be erected a building wherein shall be kept bandages, splints and medicines, in order that "first aid" may be promptly administered in case of accident. The act was passed by the last Legislature upon petition of the United Mine Workers. Some of the companies have engaged physicians to instruct their foremen how to handle and care for injured employees.

Dinner to Professor Waldeyer.—The Medical Faculty of the University of Pennsylvania gave a dinner at the University Club October 28th in honor of Dr. W. H. G. Waldeyer of Berlin.

Temporary Hospital for Contagious Diseases.—The committee in charge of the "Mischianza" which to be held at the Academy of Music November 11th to 16th for the benefit of the McKinley Memorial Hospital are to erect at once near Fort Mifflin a temporary hospital for the treatment of smallpox and other contagious diseases. The proposed permanent hospital has received the endorsement of city officials and physicians.

Philadelphia Academy of Surgery.—At the meeting held November 4th Dr. John B. Roberts reported a case of gastrostomy done under local anesthesia after codeine, hyoscine and strychnine had been given hypodermically. The patient had fracture of the femur at the same time. Dr. O. H. Allis demonstrated a method of intestinal anastomosis in which all the suture material is left on the inner side of the gut. He has not had satisfactory experience with the Murphy button. He believes that there is little to fear in the way of infection from passing sutures through the entire thickness of the intestine.

Dr. J. Chalmers DaCosta exhibited a patient upon whom distal ligation for innominate and carotid aneurisms had been done two years ago. The patient has a syphilitic history. The vessel-walls were in such bad condition that ligation between the two aneurisms was impossible. The carotid and subclavian were both ligated, the former just before its bifurcation. The innominate aneurism has been practically cured. The carotid has apparently reformed. Operative interference is now thought to be out of the question.

CHICAGO.

Medical Research.—Scientific research into the causes and treatment of infectious diseases will be begun within the next few weeks at the University of Chicago under the auspices of the Rockefeller Institute, and the supervision of Dr. Ludwig Hektoen of Rush Medical College. The $200,000 endowment set aside by John D. Rockefeller provides for equal distribution of the fund during the first ten years of research, and the University of Chicago receives a small share of the first year's apportionment to carry on research in a line that hitherto has been but little attempted. In the investigation at the University of Chicago a special man will be chosen, who will give his entire time to the work. Instructors in the department of pathology in the University of Chicago declare that the research which is now enabled to proceed in better form than before the establishment of the institution will enable the medical profession to secure a knowledge of the treatment of certain diseases that have hitherto baffled the best physicians.

Bedside Clinics.—At a meeting, of the Physicians' Club of Chicago, held October 28th, the

subject of "Clinical Teaching in Hospitals and Dispensaries" was discussed. Dr. Robert H. Babcock discussed the interests of the community, and Drs. Robert B. Preble and James B. Herrick spoke of its importance to the student and its benefits to the patient. The possible abuses and necessary safeguards were dwelt upon by Daniel D. Healy, Warden of the Cook County Hospital. He said that private or bedside clinics were abuses. The bedside clinic, according to Mr. Healy, is of no possible benefit to the patient. He is disturbed by the questions and examinations which interfere with those great restoratives of Nature, rest and peace. Clinical teaching in the hospital should prove of some benefit to the student, but he is only a small part of the body politic, and the damage done to those who are under his investigation far offsets the benefit to himself or to society. The speaker said that he had spent a good deal of his time in questioning the inmates of the hospital, and he had found that a general dread existed among patients in regard to the custom of bedside clinics. In some instances this dread amounted to positive agony, which might be compared to the agony of Christian martyrs awaiting their turn in the Coliseum to make a Roman holiday. Those of the patients who might be classed as "material" dreaded the punchings and the handlings and the lectures that were sure to be forthcoming in their cases. Those that were not "material" were kept in anxiety, terror and dread. At any moment they might be "material" and at almost all of the moments of the night and day their rest was disturbed and their treatment retarded by the presence and disturbances of the bedside clinics. So he thought that as the County Hospital had on its staff the most eminent scientists and physicians, its inmates were entitled to exactly the same treatment that these eminent physicians prescribed for their private patients. As a first principle of treatment they all insist upon silence, rest, and absence of excitement. If any inmate of the hospital could pay for treatment outside, he would have the street roped off, tan-bark spread in front of his house, the doorbell muffled, felt shoes on the trained nurses, and the neighboring children hushed or transported. In the County Hospital these people came to the institution helpless, almost without power of thought, and, at any rate, without power of decision. He had the highest regard for the various members of the hospital staff, and believes that the County Hospital as an educational factor has turned out the finest men in the medical profession. They are hard-working, painstaking men, and their lectures in the public clinics are of inestimable value, but there must be a line of demarkation somewhere, and he thought he had found it in obliterating the abuses occasioned in the past by bedside clinics. Warden Healy believes that clinics should only be given in the clinical amphitheater of the hospital.

Chicago Medical Society.—At a meeting, held October 30, 1901, Dr. J. Clarence Webster read a paper on "The Treatment of Raw Peritoneal Surfaces in Abdominal Operations." He said the older operators were only too frequently content with the removal of the disease without much concern for the condition of the parts left behind. For example, after the removal of ovarian or tubal swellings, the end of the stump was left raw and exposed, ready to adhere to the nearest structure. Adhesions were torn through and tumors shelled from their beds without care for the newly-rawed tissue except as regards the checking of hemorrhage. Small patches on the parietal peritoneum, the bladder and the back of the broad ligaments, may often be covered by loosening the peritoneum around them and bringing the edges together with catgut. Similar surfaces on a mesentery may be quickly closed by a continuous suture. Areas of omentum which have been freed from adhesions should never be left free. If slight, they should be covered with neighboring healthy omentum by means of catgut. If extensive, they should be ligatured near their base and then cut away. The common practice of leaving such omental stumps bare is a bad one. They should be turned up and buried in healthy omentum by means of a continuous suture. In this way there is little chance that they will adhere to neighboring structures. Adherent portions of appendices epiploicæ should be removed after separation and the raw stumps buried. Raw surfaces on the intestine may be covered by a continuous catgut suture when they are of very small size. On the uterus small areas may sometimes be covered by means of a running suture. If, however, the patches are large or numerous, transplantation of grafts of peritoneum or omentum may be tried. Very frequently he has simply cauterized such raw surfaces so as to form a black char. He is convinced that a charred surface is less likely to become adherent than a raw, oozing area—probably because the dead char acts as a protection from the subjacent living organizing tissue. In cases of retroversion of the uterus with posterior adhesions he has frequently carried out this procedure after freeing the organ. He has operated a second time on at least three women in whom he has performed suspensio-uteri with cauterization of the posterior surface and has been surprised at the small number of fresh adhesions present. He always cuts or cauterizes free tags of adhesion close to their base and buries the stump, if possible, under neighboring peritoneum.

Mode of Incision in Vaginal Section.—Dr. Webster also discussed this subject. The various methods of incision hitherto employed were described and illustrated by drawings and plaster models. The author advocates a new method for cases in which considerable intrapelvic manipulations on the tubes and ovaries are to be carried out, or in which the uterus is much enlarged, amputation of the cervix being necessary. The patient is placed in the lithotomy position, the vagina being well opened with retractors. After

curettage of the uterus, if this procedure be necessary, a circular incision is made around the cervix just below the attachment of the vaginal wall. This is joined by a mesial incision an inch and a half or more in length, dividing the anterior vaginal wall. The cervix being well pulled down, the wall of the vaginal vault is stripped upward until the anterior peritoneal pouch is reached. The anterior wall is also stripped somewhat from the base of the bladder. The uterovesical pouch is then opened. Through this opening the body of the uterus is brought down and the intrapelvic work carried out. At the end of the procedure the body of the uterus is replaced, the uterovesical pouch closed, the mesial incision in the anterior vaginal wall closed, and the vaginal flap again joined to the cervix. If anterior colporrhaphy is to be carried out on account of a prolapsed condition, the oval flap should be removed when the first incision is made. When an enlarged uterus cannot well be brought down, a portion of the cervix may be amputated after the vaginal wall is stripped up, and also the base of each broad ligament may be divided for a distance close to the uterus, the uterine arteries being ligatured if there be hemorrhage. At the end of the operation the vaginal flap is stitched over the cervical stump. If a posterior incision into the pouch of Douglas be needed to facilitate manipulations, it may easily be made by carrying the cervix forward. The chief advantage of the author's method is as follows: The uterus may be pulled down to a greater extent than is possible when the other incisions are employed, and as a result more room is obtained in difficult cases. Posterior colpotomy alone is chiefly used in the drainage of pelvic abscesses and hematomata occupying the posterior or postero-lateral portions of the pelvis, and in breaking up adhesions. Rarely a tubal or ovarian swelling may be removed by this route.

Removal of the Gasserian Ganglion.—Dr. John B. Murphy read an exhaustive paper on this subject, in which he detailed ten cases upon whom he had performed the Hartley-Krause operation. He favored this operation rather than the peripheral operation, saying that the relief was permanent, while from the peripheral operation in many instances it was only temporary at best. In the discussion, Dr. A. E. Halstead mentioned six cases upon whom he had operated, four of which were operated by the Hartley-Krause incision, and the other two by the Cushing incision. Dr. Carl Beck reported four cases of removal of the ganglion. One of his cases had been operated upon fourteen times by different surgeons, the fourteenth operation affording permanent relief. Dr. A. J. Ochsner called attention to an apparatus by Dr. Crile, of Cleveland, for the prevention of hemorrhage in all operations in the distribution of the carotid vessels. Dr. Christian Fenger favored trying the peripheral operation before resorting to the more radical or Hartley-Krause method. He had done the peripheral operation in three cases, the patients being relieved for years, if not permanently. The mortality from peripheral operations is almost *nil*, while from the Hartley-Krause and other methods it is ten per cent.

Home-Treatment of Pulmonary Tuberculosis.—Dr. Robert H. Babcock, in discussing this subject, believes that the real reason for the hopelessness on the part of the practitioner in obtaining satisfactory results in the home-treatment of tuberculosis lies in the fact that he depends too much on medicinal therapy. The most successful treatment lies, not in the use of medicinal agencies, but in the hygiene of the patient's life. Although these requirements can be best secured in a sanatorium, they can be obtained at the patient's home regardless of the climatic conditions that prevail there. Food should be taken at short intervals; it should be easily digested and assimilated, and should be of the most nutritious character in the smallest bulk. Good results are obtained from the use of milk and raw eggs. The patient is ordered to drink a glass of heated but not boiled milk the first thing after waking in the morning, and thereafter every two hours during the day, regardless of his meals. Raw eggs are taken, beginning with one after each meal, and increasing by one daily until as many as possible are consumed. Exercise is to be permitted only when the patient is free from fever and a febrile reaction does not follow exercise. The patient should spend the entire day out-of-doors, without regard to the condition of the weather, proper precautions being taken to prevent the patient from taking cold. Hydrotherapy is highly important. The one essential condition is that all measures should be followed by a good reaction.

GENERAL.

Medical Society of City Alumni, St. Louis.—The Society met Thursday, November 7th. Dr. Ludwig Bremer read a paper on "Artefacts of Blood-Examinations" and Dr. R. F. Amyx reported "A Case of Gunshot Wound of the Intestines with Nineteen Perforations."

Outbreak of Plague.—The usual recrudescence of this epidemic is now beginning to make itself felt. Thus far the march has been regular, though somewhat delayed and repressed, especially from the standpoint of numbers. New parts are becoming involved and the disease is manifesting itself in old foci of infection. On September 23d the plague was manifest in Italy and also made its appearance in France about the same time. In India for the week ending September 6th 6,455 plague cases and 4,394 deaths were registered. Egypt shows cases; South America is again reporting the disease, and its continued presence in San Francisco admits of no doubt.

Medical Library to McGill.—Dr. Osler of Johns Hopkins University has given to the medical library a number of rare books on medicine. The medical library has been much improved in the alterations of the building.

Health Conditions in Havana.—A statement concerning the vital statistics of the city of Havana for the month of September, 1901, compiled from official reports on file in the Division of Insular Affairs of the War Department, shows that the health conditions were decidedly the best attained in any month. The least number of deaths occurring in any previous September since 1889 was 496 in 1899, the greatest number 2,307, in 1898; average, 877. For September, 1901, there were 339 deaths. The lowest death-rate for September in the years referred to was in 1899, when it was 34.48 per thousand. For September, 1901, the rate was 15.64 per thousand. Taking the yellow-fever year as beginning April 1, the record of the last eleven years shows that, for the six months up to the 1st of October, the smallest number of deaths from this disease occurred in 1899, when there were 36 deaths; the greatest number in 1897, when there were 659 deaths; average, 296 deaths. This year, during the same period, there were only five deaths. Since the 1st of March, 100 men have been engaged daily in killing mosquitoes in various ways, and the result is said to be that instead of having fifty-two deaths from yellow fever and thirty-two from malarial fever, the average in September, there were two deaths from yellow fever and eleven from malarial fever last September. No smallpox has occurred for a year, and there were scarcely any cases of other infectious diseases.

Quarantine Against Liverpool and Glasgow.—Telegrams from Galveston, Tex., report that the State Health Department has issued orders to enforce quarantine against all vessels from Liverpool and Glasgow on account of the prevalence of bubonic plague at those English ports. Seven or eight ships from Liverpool and Glasgow are now en voyage to Galveston. All vessels will be detained ten days at Quarantine Station, and for an indefinite period should there be sickness on board.

Certain Trees as the Propagation of Mosquitoes.—The following preliminary note from the Marine Hospital Report is of interest. The completed work will at some future time form the subject of a special bulletin of the Yellow Fever Institute. Dr. B. M. Corput, who makes the report, says: "I have to respectfully submit the following preliminary report concerning some experiments I have been making in connection with the breeding of mosquitoes in proximity to certain kinds of trees. I hung cans filled with fresh water in thickets of oak trees, pine trees, china ball trees, and palmettos. The water in all cans was from the same source and was drawn at the same time; the cans were about the same size and were hung in about the same manner, as I tried to make the conditions as nearly the same as possible in everything except the kind of trees the can was hung in. My observations were as follows: In the oak and palmetto the mosquitoes bred readily; in the pine there were some wigglers in the can at the expiration of about three weeks, but they were not nearly so abundant as they were in the cans which were in the oak and palmetto. In the can hung in the china ball bushes there were no wigglers at any time, although I watched it carefully for five weeks. I have been obliged to discontinue my experiments for this season, as the leaves have almost all fallen off the china ball trees, but I hope to be able to make them more exhaustive next season. I would also like to try some other varieties of trees, *i.e.*, eucalyptus, camphor, and castor bean, and have to request respectfully that I be allowed to purchase a few trees of each variety to plant at this station for the purpose of continuing these experiments. While I have not yet been able to carry on this work for a sufficient time, and extensively enough to make the results positive, I believe that the china ball tree does to a great extent, if not entirely, prevent the breeding of mosquitoes in their immediate vicinity. To what distance from the tree this applies I have not yet observed, as I did not begin the work until rather late in the season. It seems to me, however, that the matter is worthy of further investigation and I hope that other officers who may have opportunities for making observations on these lines will do so, as, should the fact that the china ball tree prevents the breeding of mosquitoes be proved, it would aid much in the prevention of diseases which are transmitted by that insect."

Report of Physicians Who Examined into Czolgosz's Sanity.—Drs. J. W. Putnam, Floyd S. Crego and Joseph Fowler, the three local physicians who examined Czolgosz regarding his mental competency, filed their report with District Attorney Penney last Saturday. Their résumé is as follows: "In conclusion, as a result of the frequent examinations of Czolgosz, of the reports of his watchers during his confinement in jail, of his behavior in court during the trial and at the time he received the sentence it may be stated that he was sane at the time he planned the murder, when he shot the President and when he was on trial.

"We come to the conclusion from the story of his life as obtained from him that he had been sober, industrious and law-abiding. Until he was twenty-one years old he was as others of his class, a believer in the Government of his country and in the religion of his fathers. After he cast his first vote he made the acquaintance of Anarchistic leaders, who invited him to their meetings. He was a good listener and in a short time he adopted their theories. He was consistent in his adherence to Anarchy. He did not believe in government; therefore, he refused to vote. He did not believe in marriage because he did not believe in law. He killed the President because he was a ruler, and Czolgosz believed, as he was taught, that all rulers were tyrants and to kill a ruler would benefit the people. He refused a lawyer because he did not believe in lawyers or courts.

"We come to the conclusion that in the holding of these views Czolgosz was sane, because

these opinions were formed gradually under the influence of Anarchistic leaders and propagandists. In Czolgosz they found an intelligent and willing tool, one who had the courage of his convictions, regardless of personal consequences.

"We believe his statement, 'I killed the President because I was doing my duty,' was not the expression of an insane delusion for several reasons. The most careful questioning failed to discover any hallucinations of hearing. He had received no special commands; he did not believe he had been specially chosen to do the deed. He always spoke of his motive for the crime as duty. He always referred to the Anarchists as having taught that the killing of rulers was a duty. He never claimed that the idea of killing the President was original with him, but that the method of accomplishing his purpose was his and that he did it alone. He is not a case of paranoia, because he has not the systemized delusions diverting to self and because he is in an exceptionally good physical condition, and his unbroken record of good health and his capacity for labor have been equal to that of his fellows. These facts all tend to prove that the man has an unimpaired mind. He has false beliefs, the result of false teachings and not the result of disease.

"He is not to be classified as a degenerate, because we do not find the stigmata of degeneration. His skull is symmetrical, his ears do not protrude, nor are they of abnormal size. His teeth are regular and his palate not highly arched. Physically he has not a history of cruelty or of perverted tastes and habits. He is the product or Anarchy, sane and responsible."

Denti di Chiaie (Chiaie teeth).—The following item on dental infection is given by Dr. J. M. Eager in the last Marine Hospital Report: "On the examination of certain Italian emigrants embarking at this port, one is struck with the frequency of a dental peculiarity common among the inhabitants of the Italian littoral and known as 'denti di Chiaie,' or Chiaie teeth. This defect was first described by Prof. Stefano Chiaie, a celebrated Neapolitan, and bears his name.

"The impairment of the teeth, often not amounting to more than a mere imperfection, is of particular interest, owing to the fact that Italians who are subjects of the defect frequently present themselves before the medical practitioner in the United States. The deterioration, however, is an acquired one, due to local geological conditions and so, because of altered hygienic surroundings, will not pass beyond the present generation of Italians in America. Strong, well-formed teeth not particularly prone to decay appear to be the rule among young Italians when they have not been subjected to the influence during infancy of the causes of Chiaie's disease. The etiology seems to be connected with volcanic fumes or the emanations of subterranean fires, either fouling the atmosphere or forming a solution in drinking water. In Naples it is more often attributable to water than to the air, and since the Serino water, brought in conduits from a distant mountain height, has been in use and local wells condemned the incidence of the disease among infants has greatly diminished. Formerly nearly all children living in the section known as Santa Lucia, along the Riviera, and at Posillipo were affected.

"The people of Pozzuoli, a town of 16,000 inhabitants, situated five miles from Naples, are marked off from the people of neighboring places by their distinguishing characteristic of black teeth (denti neri), apparently strong and serviceable, but devoid of enamel and hideously dark. The environs of Pozzuoli are everywhere volcanic. Close at hand is the Solfatara, a half-extinct crater full of cracks from which gases are constantly issuing. Some of the inhabitants of Pozzuoli drink the water of springs, a water necessarily charged under pressure with volcanic fumes; all of them are constantly living in an atmosphere filled with noisome gases.

"The theory most generally received in Italy is that these gases have a selectively hurtful effect on enamel formation in early childhood, but that the growth of the other dental tissues is not interfered with. When the cause is active during the entire period of second dentition, the whole tooth is bereft of enamel and becomes perfectly black. If the growing teeth are exposed for but a short time at the commencement of their formation, only the cutting edges of the upper incisors may be affected and the appearance, when the teeth are matured, is as if they had been browned by tobacco smoke in the same way that a meerschaum pipe is colored by smoking. Sometimes the teeth have the repulsive look of fever patients' teeth when smeared with sordes, except where covered by the half-parted lips.

"Among the better class of Italians living inland, it is the custom to go to the seashore in summer. Naples has always been a popular resort, and as a result of the temporary exposure of children brought with their parents to Naples at the time when Serino water was not used, it is frequent to see among well-to-do people an otherwise handsome face marred by a line of fine, black markings crossing the incisor teeth in a horizontal direction. This fault of development is known among Neapolitans as 'denti scritti' or writing on the teeth. The marking, when present on finely-formed, white teeth, resembles the diminutive lettering which is sometimes done on seashells for purposes of ornamentation The different forms of deterioration which are grouped under the name of 'denti di Chiaie' are thus seen to be quite unlike any other dental disease and not at all likely to be confounded with Hutchinson's teeth, mercurial teeth, caries, or other maladies of the teeth."

Tetanus from Antitoxin Serum.—The report from St. Louis is confirmed by a special correspondent, who writes: "There have been several cases of tetanus in this city following the use of anti-diphtheritic serum furnished by the St. Louis Board of Health. Within six days

eight children have died, two other children are critically ill, and possibly others are affected. The first case was that of a five-year-old child in the City Hospital, whose symptoms resembled those of meningitis to such an extent that the diagnosis of tetanus was not made until shortly before death. Others of the cases seem to have had atypical symptoms, but most of them showed the classical signs of lockjaw. One case at the City Hospital received an injection of tetanus antitoxin into the spinal canal, but without effect. Another received an intracerebral injection of tetanus antitoxin, also without effect. The city has manufactured its own antitoxic serum since 1894, the work being supervised by Dr. Amand Ravold. On August 24th a quantity of serum was taken from a certain horse, properly sterilized and tested upon guinea-pigs. This was distributed to physicians throughout the city. On September 30th the horse was again bled. On October 1st the horse showed symptoms of tetanus and was killed. The serum taken September 30th was at once destroyed, none of it having been distributed. Since the discovery of the infection of the serum all of it has been recalled, but between the time of its distribution and the time of its recall a considerable number of injections were made. Just how many cannot now be stated. It is, therefore, to be feared that a few more cases of tetanus may develop. The Health Commissioner, Dr. M. C. Starkloff, has directed an investigation of the entire matter by Dr. B. Meade Bolton, late of the New Jersey Health Department, now director of the Marion-Sims-Beaumont Pathologic Laboratory in this city, Dr. E. C. Walden (Johns Hopkins) of the J. T. Milliken Company, and Dr. Carl Fisch, a pathologist of some local repute. The coroner is also conducting an investigation."

To Guard Against Plague.—Health Officer Doty of New York has forwarded to Washington a report on the quarantine precautions he deems necessary to guard against the introduction through Atlantic ports of the plague which has broken out at Liverpool and Glasgow.

Obituary.—Dr. J. Mortimer Crawe, Sr., died in Watertown, N. Y., last week at the age of seventy years. He was the oldest practising physician in that section of the State, and was the first vice-president of the New York State Medical Association.

CORRESPONDENCE.

THE EXECUTION OF CZOLGOSZ.

To the Editor of the MEDICAL NEWS:

DEAR SIR: Agreeably to your request the following brief account of the execution and autopsy of Czolgosz, the assassin of President McKinley, is respectfully submitted:

The execution by electricity of Leon F. Czolgosz, which took place in the State Prison at Auburn, New York, on the morning of October 29, 1901, terminated the earthly existence of the most monstrous magnicide of the age. Every precaution was taken by the Warden of the Prison, under whose immediate supervision and direction the execution was conducted, to minimize the opportunity for notoriety, as well as to insure that the taking-off of the prisoner should be effected in an orderly and dignified manner.

The official witnesses, consisting of prominent New York State officials, several physicians, representatives of the respective press associations and two official physicians—Dr. John Gerin, Prison Physician, and myself—having been assembled in the execution room and received the usual admonition from the Warden as to the maintenance of order and quiet during the execution, the prisoner was conducted to the room by a guard on either side a few minutes after 7 a. m. As he entered the room his head was erect and his manner self-possessed and defiant. Immediately after being placed in the fatal chair the binding straps were quickly adjusted to his arms, legs and body, the head and leg electrodes were placed *in situ* and connected with the wire which was to transmit the lethal current through his body. The criminal offered no resistance whatever, but during the preparations addressed himself to the witnesses in the following significant language: "I killed the President because he was the enemy of the good people—the good working people. I am not sorry for my crime. I am sorry I could not see my father." At this juncture, everything being in readiness, the Warden gave the signal to the official electrician in charge of the switch, who immediately turned the lever which closed the circuit and shot the deadly current through the criminal's body. The instant the contact was made the body was thrown into a state of extreme rigidity, every fiber of the entire muscular system being in a marked condition of tonic spasm. At the same time consciousness, sensation and motion were apparently absolutely abolished.

Czolgosz was pronounced dead by the attending physicians and several of the other physicians present in four minutes from the time he entered the execution room, one minute of which period was occupied in the preliminary preparations, one minute and five seconds in the electrical contacts and the remainder of the time in examinations by the physicians to determine the fact of death.

Two electrical contacts were made, occupying in all one minute and five seconds. In the first contact the electro-motive pressure was maintained at 1,800 volts for 7 seconds, then reduced to 300 volts for 23 seconds, increased to 1,800 volts for 4 seconds, and again reduced to 300 volts for 26 seconds, when it was broken. The second contact was maintained at 1,800 volts for 5 seconds. That conscious life was absolutely destroyed the instant the first contact was made was conceded by all of the witnesses.

Immediately after the execution, the lay witnesses having departed, an autopsy was made by Mr. Edward A. Spitzka of New York, under the

direction and supervision of the official physicians and in the presence of several of the visiting physicians who were invited to attend. The autopsy occupied more than three hours and embraced a careful examination of all the bodily organs, including the brain, all of which were found to be in a perfectly normal state—a conclusion which was concurred in by all the physicians present.

In compliance with the expressed wish of the relatives of the criminal, the Superintendent of State Prisons, who was present, and the Warden, declined positively to allow any portion of the body to be removed from the Prison. Consequently, and regrettably, it was impossible to retain honorable possession of any portion of the brain for future examination and study. Accurate drawings, however, and detailed anatomical descriptions of the brain were made by Mr. Spitzka for subsequent study and report. A careful, naked-eye examination of the brain in all of its parts was also made and full notes taken thereof. The organ and its appendages appeared to be absolutely healthy and free from any abnormality whatever, thus corroborating the opinion of the mental experts who had examined the criminal during life, namely, that he was perfectly sane.

Respecting the question of Czolgosz's mental condition, it appears that all of the mental experts at his trial, on either side, namely, Drs. Putnam, Fowler and Crego for the people, and Arthur W. Hurd and myself for the defence, after repeated examinations, concurred in the opinion that he was sane. A final examination of the criminal, with reference to his mental condition, was made by Dr. Gerin and myself at the Auburn Prison on the evening before his execution with entirely negative result. In fact, none of these examinations disclosed, in the opinion of any of the experts, the slightest evidence of mental disease or mental degeneracy. On the contrary, he was regarded as exceptionally intelligent for one in his walk of life. Furthermore, this conclusion was fully corroborated by his manner, appearance and declarations in the execution room as well as by the postmortem findings. Moreover, Czolgosz's bearing, conduct and declarations from the time he murdered the President down to that of his execution have been entirely consistent with the teachings and the creed of Anarchism and stamp him as an Anarchist of the deepest dye.

85 Madison avenue, New York.

THE CAUSE OF BALDNESS.

To the Editor of the MEDICAL NEWS:

DEAR SIR: Frequent reference has been made of late in the MEDICAL NEWS to the subject of baldness. Fortunate the man who shall reveal its cause! One doctor is sure that it is due to the more vigorous intellectual activity of the male sex. Another scouts the idea and points to the head dress, and still another would have it that abdominal breathing is the cause of this distressing condition.

I am not going to reveal the cause in this short note, but there are just two facts which I have observed here that may throw some light on the subject. One is that the men wear tight hats all the time—many of them day and night—and very few of them are bald. The second is that the few whom I know are bald are those who are above their brothers in intellectual activity, such as our college teachers, preachers, etc. I am speaking now of the native population. These same bald people, following the fashion of the missionary, do not wear their hats so constantly as do the uneducated village people who are not bald. Elisha's bald head must have been a notable exception to the majority of heads in Jericho, and hence the attention he attracted. This condition of baldness, like many other conditions of disease, may be due to a combination of causes. It would be interesting to know the percentage of bald heads in a generation of men free from gonorrhea and other venereal diseases.

E. T. MILLER, M.D.

Urumia, Persia, Sept. 13, 1901.

OLEIC ACID IN COLIC.

To the Editor of the MEDICAL NEWS:

DEAR SIR: In one of your latest issues there is a note by Vevet, alluding to the use of oleic acid, in which he speaks of using this drug ten or fifteen days before an expected attack of colic. I would like to ask if any of your readers have ever been able to demonstrate a genuine periodicity in hepatic colic. I have, of course, seen cases in which one might anticipate an attack, knowing that the patient expected to take unusual exercise or was becoming careless with regard to diet, and I can imagine that a malarial dyscrasia might act as a periodic exciting cause, but, as to intrinsic periodicity, my own experience has led to considerable skepticism.

A. L. BENEDICT.

Buffalo, Oct. 14, 1901.

PARIS LETTER.

(From Our Special Correspondent)

PARIS, Oct. 14, 1901.

CONSUMPTION AMONG POSTMEN IN PARIS—BAZY ON URETERAL CATHETERIZATION—SANATORIUM FOR THE EMPLOYEES OF THE LOUVRE—THE BUBONIC PLAGUE ON BOARD THE "SENEGAL."

DR. GRENIER, physician attached to the postal and telegraphic service in Paris, has been publishing some statistics on the number of cases of tuberculosis which he has seen amongst the employees under his care. His statistics extend over six years and show a large number of cases of consumption. Thirteen per cent. of the vacations allowed were given for this disease. There were 720 cases of diseases of the respiratory organs (leaving out influenza) and 589 cases of consumption, which makes a very large percentage.

The employees who are obliged to remain in the post-offices show a much larger percentage of cases than those whose service keeps them out of doors, such as the postmen and drivers.

The discussion between Dr. Bazy and Dr. Albarron as to the usefulness of catheterization is not over yet. Dr. Bazy made a long communication to the Society of Surgery on the merits of the use of methylene blue and phloridzine as compared with ureteral catheterization. He is much opposed to this latter method and described the case of a patient who had been catheterized by Dr. Albarran, and then operated upon by him. The patient had had fever after the exploration, and the result of the analysis led Dr. Albarran to recommend nephrotomy. Dr. Bazy used both phloridzine and methylene blue and decided that the condition of the other kidney was such that nephrectomy could be performed. The operation was successful.

The establishment of sanatoria is very much talked of at present, and special establishments are being put up for different classes of people. The employees of the large stores suffer considerably from tuberculosis on account of the bad air they are obliged to breathe. The directors of the Louvre, one of the large Paris stores, have erected at Tournau a hospital containing 16 beds, where employees showing signs of fatigue may be sent.

A periodical, called the *General Review of Sciences,* organized recently an excursion to Asia Minor and Palestine. A steamer, the "Senegal," was chartered and left on the 14th of September from Marseilles. There were 186 passengers on board, amongst whom were 19 physicians. Professor Terrier, Dr. Bucquoy, Chauffard and Richardiere, physicians of the hospitals, were on board. Soon after the steamer had sailed two cases of bubonic plague were discovered among the crew, and the boat had to put back to Frioul, the sanitary station of Marseilles. The second officer has already died. The rats, which had caused the contamination, were found on the first day. Over a hundred and twenty were found in the hold. They were already in an advanced state of putrefaction and it would seem that the infection took place the last time the boat went through the Suez Canal. Orders had been given to have the steamer thoroughly overhauled, but such a precaution can hardly have been carried out effectively. All the tourists, with the exception of 13, have been inoculated.

OPERATIVE TREATMENT OF PUERPERAL FEVER—TOBACCO AND ALCOHOL WITH RELATION TO AMBLYOPIA—REFLEX NYSTAGMUS—OPTIC NERVE IN BASAL FRACTURES.

E. BUMM, at the Verein der Aerzte in Halle a. S., July 3, 1901, read a contribution on operative treatment of puerperal fever, in which he made the following points: Notwithstanding all aseptic and antiseptic precautions cases of septic puerperal wound infection have not materially decreased in practice among private families. Instances of septic and fatal puerperal fever, which resist all local and systemic treatment are still so common that the physician is inclined to ask whether surgical intervention would not be advisable. The simplest and most often employed surgical treatment of these cases is curetting. It has the great objection that in the presence of streptococci, which are by all means the commonest germs at the bottom of these cases, a sharp denudation of the endometrium opens wide the avenues for a rapid spread of the germs over and into the raw surface, then into the metrium, finally through veins and lymphatics into the general system. These observations are applicable to all cases of this class, no matter whether the surgeon is dealing with a case of pure endometritis, retained placenta or undischarged fruit in abortion, so long as sepsis is locally present. The only safe way of emptying the uterus in this class of lesion is with the bare fingers, because every possible degree of cleansing can thereby be accomplished and little or no damage done to the tissues. The next surgical treatment is extirpation of the infected uterus. Here again the limitations appear to be drawn equally sharply. In two successful cases out of five, Bumm found in the former true sapremia, in the latter streptococcus infection. No matter what precautions are taken these germs almost necessarily invade the wound and set up either septic pelveoperitonitis or local abscess or general peritonitis. Sapremic endometritis practically always gets well of itself, without much far-reaching gangrene. Hence, in the presence of both diseases, it is reasonable to say that extirpation of the uterus is not indicated nor justifiable. When the infection is active enough to spread, it does so either over the mucous membrane into the tubes or through the venous and lymphatic channels into the parametria. Tubal infection leads directly to pelvic tumor or after adhesions with the adjoining organs. As a rule gonorrheal abscess permits early operation with a rather good operative prognosis, but it is otherwise with the streptococcic. Early evacuation of such collections commonly finds an active virulent pus which may immediately and fatally infect the general peritoneal cavity. Such a calamity may also occur in an abscess many weeks old. It is therefore wisest to assume no risks, but to reason that localization indicates some success on the part of Nature in combating the disease. It is, therefore, best to assist this process until the pus shall probably have lost its poison and then to hasten matters by evacuation. Spread of the streptococci directly through the myometrium or through the lymphatics to the peritoneum, usually means septic peritonitis. For this dreadful state all known means fail to do any good, multiple incisions, free irrigation, wide-open drainage, etc. When an abscess has formed and Nature made some progress in fighting the dis-

ease surgery may succeed. But in these cases evacuation must occur where the abscess has become adherent to the abdominal wall. The most minute care must be taken even then to provide against any pus reaching the abdominal cavity. In the truly pelvic abscess, which may be drained by the vaginal route, a similar precaution must be followed. At first it may be seated high up and very unsafe to puncture. The best dictum to follow is that when possible all abscesses demand first expectant treatment, until they manifest themselves by a swelling in the vagina or a palpable tumor through the parietes. Evacuation by either route will then be as safe as possible. Puerperal pyemia is another most serious condition in which surgery accomplishes but very little. It is usually a matter of septic thrombosis in any or all of the veins about the uterus, tubes and ovaries. Too often interference spreads the disease to a fatal degree.

BERNHEIMER (Innsbruck), at the meeting of the Ophthalmological Society in Heidelberg, August 5, 6 and 7, 1901, gave the following observations on the relations between tobacco and alcohol and amblyopia. Twenty cases of either or both combined have been under his care during the last year. Eight of these were railway employees who had been sent to him for early cataract. These did show a reddish tint apparently in the cornea, which on careful examination was shown to be an axial change in the retina. This is a very early symptom of the disease of functional nicotine or alcoholic derangement, which is only passingly mentioned in some of the text-books and not at all by others. Since the cure of this disease rests largely upon an early diagnosis, search for this sign must be carefully made. The same observer has noted four patients in whom anomalies of refraction and two in whom dry conjunctivitis produced a purely reflex nystagmus. In one form the nystagmus depends upon hypermetropia when without due correction the eyes are used for near-work. The reflex is then to be explained by increased accommodation and convergence. The second class of these two seemed to depend entirely upon dry catarrh of the conjunctiva with or without hypermetropia. This class of case is not mentioned in literature. In one of his patients it was enough simply to lift the lids or even the lower lid away from the eyeball without making any pressure thereon to excite the most active possible nystagmus. The cause seems to be irritation of the end-filaments of the fifth nerve by the sudden drying of the cornea and the conjunctiva when these are exposed to the air by lifting away the lids. In both cases pure reflex is at the bottom of the trouble, in the former by undue muscular strain and in the latter by sensory, then motor irritation.

UHTHOFF (Breslau) gave a contribution on the state of the optic nerve due to hemorrhage into its sheath after fracture of the base of the skull. He has had two cases in which large hematomata developed and an autopsy was had in each case. All four nerves showed marked hematoma of the sheath directly behind the bulbus oculi. During life the nerve-disc was prominent (very prominent in one case) and in both very like a choked disc. Death came early in both patients and in each the fractures involved the middle cranial fossa and showed both extra- and intradural hemorrhage. In neither subject was the roof of the foramen opticum affected by the break in the bones. Ophthalmoscopic examination showed during life with absolute accuracy optic neuritis, venastasis, edema and massive prominence of the papilla. He offered the following points as suggested by the autopsy: (1) The relation between the optic nerve hematoma and the optic canal. The latter was in each case intact, but the blood had traveled along and within the sheath directly from the cranial cavity. Other authorities, on the contrary, point to the frequency with which the optic canal is involved in a fracture of the base and the nerve shows the lesions of neuritis. Panal relates a case in which real bleeding took place from the eye-cavity, but the optic nerve escaped. (2) The significance and value of an ophthalmoscopic examination in all possible cases of suspected basal fracture and especially for the signs of neuritis, venastasis and bulging of the papilla. His findings seem to prove that hematoma does not produce an anemia of the retina, as is supposed to exist with embolism and thrombosis. (3) Functional disturbances due to hematoma of the nerve-sheath were theoretically enumerated. (4) Other causes of such hematoma might be any other intracranial bleeding, apoplexy, pachymeningitis hemorrhagica, nephritis, scorbutus, hemophilia, etc. At best it is a rare condition.

SOCIETY PROCEEDINGS.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, Held October 1, 1901.

The President, Joseph Collins, M.D., in the Chair.

Contribution to the Study of Spinal Fracture, with Special Reference to the Question of Operative Interference.—Dr. George L. Walton of Boston presented a paper on this subject, dwelling particularly on the question of whether it was not desirable to make early operation in this class of cases the common custom. The author said that there were no symptoms which would lead one to assert that the cord was or was not unquestionably crushed. In the cases of so-called complete injury one finds immediate relaxed motor paralysis and entire absence of rigidity or other irritative sign in the motor sphere. Partial injury to the cord might be indicated by slower onset of paralysis, its unilateral or irregular distribution, the partial retention of the reflexes and subsequent improvement. In fracture with total transverse lesion the area of anesthesia was generally sharply marked, and the level was materially below the seat of the lesion. The classical symptoms of complete trans-

verse lesion certainly do not indicate conditions beyond repair. Incomplete anesthesia points to incomplete lesion of the cord; the same is generally true of anesthesia of limited or unilateral distribution. Injury to the nerve-roots alone sometimes appears in the cervical region after stretching and bruising, perhaps with temporary displacement of vertebræ. The diagnosis of local concussion of the spine was still applied by certain authors to such cases. Retention of urine was the rule in all varieties of spinal fracture with injury to the cord whether the lesion involved the cervical, dorsal or lumbar cord. This probably showed that mechanical conditions prevent the escape of urine so long as the propulsive force is lacking. The symptoms referable to vasomotor disturbances are evasive and baffling. The usual rise of surface temperature might perhaps be explained by the dilatation of superficial blood-vessels due to the cutting off of the vasoconstrictor influence from the medulla. The absence of sweating tends to fortify the theory that the principal sweat center lies in the medulla, the fibers being interrupted in their course by the lesion. Sweat secretion appears to be due to specific nerve influence conducted by specific nerve fibers and not to heat. It is now generally recognized that the knee-jerk is lost in cases of complete destruction of the cord and cases of spinal fracture constitute no exception to this rule. The superficial reflexes were generally lost or diminished in these cases, and were probably always lost in the complete lesions. The Babinski reflex was a common later phenomenon, but he would doubt its occurrence in cases of total destruction of the cord without reparative process. The local signs, such as the formation of a knuckle, were very variable and not of much significance. Operation often shows that the apparent irregularity is of no importance. It should be remembered that a great variety of curves are found in the back in healthy persons free from injury. This statement was fortified by the exhibition of a series of tracings from the backs of healthy students in the Boston Normal School of Gymnastics. The Roentgen rays might prove of value in making the diagnosis, but in his own experience this method had not yielded satisfactory results. The prognosis in cervical cases without operation was generally grave, death usually occurring within a few days. In cases of fracture of the dorsal or lumbar region without operation the prognosis was better, but still very grave. The fatality in non-operative cases was about 80 per cent. The statistics at hand were not very reliable regarding operative cases, because many unsuccessful cases were not reported. The cases operated upon at the Massachusetts General Hospital since 1870 yielded a mortality of about 64 per cent. In some quarters laminectomy was not advocated, or was even denounced. Apprehension regarding the danger of the operation had been entirely allayed, and many cases had been reported showing that laminectomy is not dangerous by reason of the weakening of the spinal column. It was doubtless true that in most cases the crush of the cord had taken place. The author was inclined to think that owing to the decided limitations of our diagnostic ability it was well to resort promptly to operation in all cases, except the moribund and those with great displacement, and give the patient the benefit of the doubt. According to his personal experience the course of the operative cases coming under his observation had been more favorable than he should have expected without operation from his previous experience and his knowledge of the literature. The neurologist was often asked whether it was wise to open a dura at the operation, and his answer should be in the affirmative. An edematous condition of the arachnoid was apt to exist, and would be relieved by such a procedure, but the chief reason was the opportunity this afforded for inspecting the cord. Of late the custom had been not to suture the dura, but to leave it open. It had been the usual custom in the past to secure drainage for a day or two, but various recent operators had demonstrated that it was not at all necessary, and by eliminating drainage one could secure quicker healing and greater immunity from sepsis. In cases of grave shock it would seem to be reasonable to delay operation if only to better interpret the symptoms. Rapidity of operation was important, and the surgeon need not fear injuring the cord by the use of forceps.

Dr. Charles L. Dana said that his own experience had led him to believe that the operation is practically safe, and that the spinal column itself is not injured by the operation. He had not had any fatal results in his operative cases, about half a dozen in all, and two of them were cases of injury in the cervical region. It was a matter of astonishment to him that such long and severe operations could be done upon these patients without sacrifice of life. He must confess, however, that the ultimate results of these operations had not been satisfactory, according to his observation. He had seen some improvement in motion and in the bladder symptoms in these cases, but that had been about all, and it was quite possible that such improvement would have occurred without operation. If by clinical observation one could be sure that the cord was crushed one should not recommend operation. This could often be done. If there was a line of anesthesia coinciding with the line of paralysis, and this co-existed with the absence of knee-jerks, he would feel almost positive that the spinal cord had been cut across although there were certain exceptional cases affecting the cervical region which did not seem to follow this rule. It seemed to him that the operation performed by Lloyd, and which the speaker had seen employed by Abbé, was the quickest, safest and most effective. The author had done a service in bringing up this subject and urging a more persistent effort to relieve this distressing class of cases. The general opinion among surgeons was that this was a class of cases which

hold out but little hope of benefit from operation.

Dr. Edward D. Fisher said that he had had a number of cases of fracture of the spine under his observation, and in the main he would agree with the reader of the paper that an operation is advisable. He would do this because death rarely occurs as the direct result of the operation. Where there had been a fatal termination he felt that the same result would have occurred if there had been no operation. In two cases that had been under his observation in which cocaine had been used, the operation had been done as well as under general anesthesia. In one of the cases the injury had followed a dive in shallow water, and in the other from an acrobat diving off the shoulders of another acrobat. The lesions had been about the same in each case, and because of the situation of the lesion they had been afraid to administer a general anesthetic. When the cord was touched there was a sensation of pain, but no localization, and the operation was conducted without any more shock than with general anesthesia. He agreed with the reader of the paper that it was almost impossible to make an accurate diagnosis between cases in which the cord had been partially or completely crushed. He did not believe that a lesion through the cervical region, with an absolute loss of reflexes, positively indicated that there had been a complete destruction of that region. Sometimes on cutting down and exposing the cord one observed very little change in the appearance of the cord until the dura had been cut. Even then there might be very little change because of a hemorrhage in the substance of the cord. The distribution of the sensation in almost all of these cases was irregular, so that the classical picture was rarely observed. In many cases where there had been absolute loss of reflexes there had been partial recovery—indeed, in his experience it had been the rule to see only partial recovery.

Dr. Graeme M. Hammond did not think it was always possible for the neurologist to say that the symptoms presented were positively indicative of complete destruction of the cord. In one case coming under his observation, in which a young man had fractured his fourth cervical vertebra by diving in shallow water, there had been evidence of complete injury to the cord. He had been operated upon a year or two afterward, but it was needless to say there had been no resultant improvement. In another case in which there had been an incomplete injury to the cord, and in which operation had been resorted to shortly afterward, there had been complete recovery and the man had returned to his occupation of wrestler. Within a few days he had seen a very interesting case. It had been first reported four years ago. Several bales had struck the patient on the back, and almost immediately he had presented the symptoms of tabes, pure and simple. He had had no reflexes and almost complete anesthesia with the Romberg symptom. He had been operated upon twelve weeks after the injury, and had made a complete recovery with a return of reflexes. He had seen this man within a few days, now twelve years after the injury, and he had then presented absolutely no symptom of injury to the cord. Such cases naturally lead one to be rather optimistic in regard to the mild cases. The fact that there was spinal deformity meant nothing, for, in Pott's disease of the spine there was often very marked deformity without any spinal cord symptoms. If the symptoms presented in a given case pointed to the total transverse lesion of the cord there was nothing to be done but operate, and even this gave a forlorn prognosis. In the milder cases the operation should be undertaken as soon as possible, as here the prognosis was much better. He would operate in any cases, no matter how hopeless it seemed, because nothing else could be done, and the patient was no worse off than before. In the milder cases it was our duty to operate.

Dr. B. Sachs said that the question arising regarding operative interference in these cases was similar to the question of surgical interference in Pott's disease or in cases of tumor. The answer to this question must depend very largely upon the stage. He could not agree with Dr. Hammond that operation should be done because, to say the least, the person would be no worse. It was still the fashion to delay surgical interference until everything else had been tried, whereas if surgical interference was to do any good it should be practised at once. In cases of fracture of the spine, therefore, whether complete or incomplete, operative interference at the earliest stage could do no harm and might be productive of a great deal of good. The differential diagnosis between complete and incomplete crush was difficult. When the crush was complete the reflexes were almost invariably absent, whereas if there was more or less maintenance of conduction through the cord the reflexes were apt to be impaired or exaggerated according to the site of the lesion. The dissociation of sensation was, in his opinion, an exceedingly valuable symptom, as it pointed out the rather moderate involvement of the cord. He was inclined to think that it was often a root symptom and not an indication of absolute involvement of the cord itself.

Dr. J. Arthur Booth said that his experience had been limited, but he had not seen any great benefit from operation, although it should be said that operative interference had been resorted to at a late stage. It seemed rational to treat fractures of the vertebræ on the same general surgical principles as fractures in other parts of the body. In two of his cases the complete paraplegia existing prior to operation had remained unaffected, though there had been some diminution of anesthesia and improvement in the condition of the bladder.

Dr. Joseph Fraenkel referred to a case at the Montefiore Hospital of fracture of the spine. The patient had been admitted a year and a

half after the accident, and had been walking around since the injury. Although the operation had been done late, it was worthy of note that three years and a half after the injury the autopsy showed that the cord had not been entirely destroyed. About six years ago he had presented to this Society a paper on the differential diagnosis between complete and partial destruction of the cord. In four cases in which the reflexes had been lost the autopsy had shown complete destruction in only one of the cases. That shock alone was sufficient to destroy the reflexes was an old physiological dogma. He wished to insist that it was important to note the condition of the deep and superficial reflexes, because for the maintenance of the deep reflexes it was necessary that the cord be intact, whereas this was not requisite for the superficial reflexes. The plantar reflex was the one that was not destroyed.

Dr. George E. Brewer said that there was a greater inclination in Boston than in New York for operating upon these cases. He had personally passed through various stages of opinion regarding operating on these cases. At first he had been influenced by those around him in Boston. The general rule had been when there was paralysis below the point of injury and involvement of the sphincters to do an exploratory operation. He could not recall a single one of these cases that had been benefited by the operation, though he felt that they had all been examples of complete crush of the cord. In New York City the surgeons had been perhaps a little too conservative. Injury in these cases is either a crushing one or there is a hemorrhage within or without the cord; hence the outlook from operation was not good. The cases of hematomyelia recover without operation; cases of severe crushing injury, even with operation, do not. This seemed to be the prevailing view here at the present time. Possibly some of the early successes were in cases of unrecognized hematomyelia in which, of course, recovery would have taken place entirely independently of the operation. Last winter he had seen a girl with injury of the last lumbar vertebra. There was a sensory paralysis and complete loss of control of the bladder and rectum. Dr. Hammond had examined the case and, believing that there was no transverse lesion, had urged operation. The speaker had performed laminectomy and had found only a small spicule of the bone. The patient had recovered from the operation and at the end of six weeks had regained control of the bladder and rectum. When seen two or three months after operation she had almost completely recovered. Had it not been for the advice of Dr. Hammond he would have looked upon this case as an improper one for operation. It had been his practice to introduce in these cases a very small rubber drain.

Dr. A. C. Brush of Brooklyn said that he had seen quite a number of these cases. In the past six months he had had several X-ray photographs made, and they had been so variously interpreted by those who had seen them that they had ceased to have any value. A case was mentioned in which great improvement had followed the removal of a spicule of bone in a man brought into the Kings County Hospital after a fall. A diagnosis had been made of fracture of the arch. An immediate operation had been done and the arch found to be broken down, but this was not pressing upon the cord, but a fragment of the tenth dorsal vertebra. This case had impressed him with the value of operative interference as a means of diagnosis.

Dr. Joseph Collins said that he had only seen a few cases of fracture of the spine, and these at a remote date from the injury. The future of spinal surgery for broken back, he affirmed, lay entirely in the hands of the neurologists—in other words, upon the diagnosis. This had been clearly brought out in the cases cited by some of the speakers this evening.

Dr. Walton, in closing, said that the statement made by Dr. Dana regarding the symptomatology of complete crush of the cord seemed to impeach the observations of a number of trustworthy observers. Regarding late operations he would say that if the pressure had been removed there was no use in operating, and if the pressure had existed for many months there was little prospect of doing any good by operating. Theoretically the late operation would be useful in cases in which symptoms arose from the formation of callus on the inside of the laminæ, and the pressure on the cord, but his personal experience did not include any case of this kind. Instead of picking out an occasional case for operation he would advise picking out an occasional case in which an operation should not be done—in other words, a case which was in great shock and practically moribund.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, Held October 14, 1901.

THE Vice-President, William McCollom, M.D., in the chair.

The Repression of Quackery.—On the recommendation of the Executive Council the Chair was authorized to appoint a committee of five to submit a plan of action for the repression of quackery in the State of New York to be recommended by the Association to other medical societies.

Cholelithiasis and Its Treatment, Medical and Surgical.—This discussion was opened by Dr. William H. Thomson, who spoke of the value of contrasts, as strikingly shown in calculus of the gall-bladder and calculus of the urinary bladder. Both present very similar indications for surgical relief, but with this statement all resemblance ceases. Why does it cease? In the first place, biliary calculi may present absolutely no symptoms during life; whereas calculi in the bladder nearly always give rise to symptoms.

It is estimated that at least 10 per cent. of all males over the age of forty have gall-stones which give no signs of their presence during life; while in women of fifty and over the percentage is as high as 25.

In the case of urinary calculus the diagnosis is a very easy matter. We can apply tests to the urine, we can see the stone by means of the cystoscope, and can feel it with the sound. But we have no means of seeing or feeling gall-stones or even of getting a specimen of bile. These contrasts, however, are by no means as great as those regarding the manner in which these respective concretions come into existence.

The Formation of Gall-stones.—Very important progress has of late been made in our knowledge on this point. We now know that a gall-stone has nothing to do with a general constitutional state. Hence, in this connection, there is no such thing as a uric-acid diathesis, a phosphatic diathesis, etc. Instead, gall-stones are purely local in origin. They do not come from the liver cells and do not result from a fault in the secretion of bile. They originate lower down, just as gonorrhea is not a disease of the kidney. This recent knowledge is a great gain and it enables us to dispense with a great many of the supposed remedial measures that were in use twenty-five years ago. For it we are principally indebted to Naunyn, of Strasburg. The bile, as secreted in the liver, is very watery and has very little *vis a tergo*. In amount it is about equal to the urine, from two to three pints a day. When most rapidly secreted, during the active periods of digestion, it passes into the intestines, being propelled by the pressure of the diaphragm and the abdominal muscles and by the intestinal peristalsis. The mouth of the common duct has a sphincter and when active digestion ceases the sphincter is closed. During the night and other intervals of digestion the bile flows back into the reservoir provided for it—the gall-bladder. In the constitution of bile the main inorganic ingredient is lime (calcium). It is normally in solution and it would remain so but for its tendency, under certain conditions, to combine with another ingredient, namely, the red coloring-matter of the bile, thus forming a precipitate of calcium and bilirubin. Layer upon layer of cholesterin is deposited and sometimes the formation of gall-stones is very rapid. This cholesterin, to which the bulk is mainly due, forms with great rapidity around a stone already impacted in the duct. As to what causes the original precipitation from the bile of the calcium and bilirubin, and as to what causes the further accretions of cholesterin, this is always due to a local catarrh of the mucous membrane of the biliary passages. Cholesterin is a substance widely distributed throughout the body, and especially in the nervous system. Yet it is most commonly produced by the degeneration of epithelial cells, and hence is always found in pus. It is not, therefore, a normal ingredient of the bile, except in very small quantity, and then derived from the epithelium of the gall-bladder. This explains the clinical fact of the great preponderance of cholelithiasis in women. A very important factor in its production is simple stasis or stagnation of bile, and this condition is not difficult to understand when we reflect upon the common inactivity of the muscles of respiration, and add to this relaxation of the abdominal walls, frequently accompanied with ptosis. The most important factor of all remains to be noted. There is not simply a catarrhal condition, but always an infection by micro-organisms, which travel up from the intestines. In at least three-quarters of the cases the particular micro-organism is the bacillus coli; but in some instances we have streptococci, staphylococci, typhoid bacilli, and other germs. Hence, as we see, it is a purely local affair. As to biliary stasis, this is largely due to the habits of the patient, and chronic constipation is one of its chief causes.

Diagnostic Symptoms.—In the first place, jaundice is present in from 50 to 60 per cent. of cases of biliary colic; but so long as the concretion has been caught in the cystic duct no jaundice will result. If there is no jaundice we ought to have the urine tested for biliary pigment, a mere trace of which will throw light on the diagnosis. Secondly, signs in connection with other symptoms of cholelithiasis. There is very little doubt that such signs are due to toxins, and they in every way resemble those in urinary fever, which we now know are caused by the colon bacillus. In the next place it is worthy of consideration that we may have a virulent inflammation of the gall-bladder, sufficient to produce hepatic abscess, and yet find no symptoms of biliary colic. In every case where there is any reason to suspect such a condition the urine should be examined for leucocytosis.

Treatment.—Have we any means, aside from surgical interference, of dealing with gall-stones more satisfactorily than in former days? Dr. Thomson said he thought we had, in the great majority of cases, until the calculus is tightly impacted in the ducts and even after that in a great many instances. To Plimpton, of London, we are indebted for our knowledge of the solubility of biliary calculi in oils of various kinds, such as sweet oil, almond oil, and petroleum oil; which act first on the cholesterin. This, said the speaker, was no longer a matter of hypothesis with him. He was in the habit of relying on olive oil, and he had a special way of giving it. For ten nights in succession the patient takes from one to two ounces in hot milk. Then the oil is omitted for a week, and this course is kept up for a number of months. Oil exerts a special action on mucous membranes in general, and here it has the direct effect of increasing the watery secretion of bile. He said he had from 50 to 80 recorded cases in which this treatment was successful. In addition to the treatment of the gall-stones themselves, we have to deal with the conditions which tend to cause intestinal catarrh, and for this purpose there is nothing so efficient as benzoate of

soda. Next in efficacy comes salicylate of soda, and he is in the habit of prescribing ten grains of each of these three times a day after meals. Hoffman's anodyne and chloroform, which have been so long in use in cholelithiasis, also have some solvent action.

Medical Treatment of Acute Attack and Management of Chronic Gall-stone Disease.—Dr. Leonard Weber said that in the treatment of cholelithiasis physicians always could, and can, do a great deal for the relief and cure of their patients, but vastly more can now be done to save life in cases not amenable to medical treatment, since surgeons, following in the path opened to them by Langenbuch, have known how to incise the gall-bladder and clear of gall-stones that viscus as well as the ducts. For an acute attack of biliary colic are required a hypodermic injection of morphine, a hot poultice over the upper abdomen, and a large enema; followed, when nausea and vomiting have ceased, by calomel or compound cathartic pills. For some years he has been in the habit of following up an acute attack for a week or more by enemata of from four to eight ounces of warm olive oil, carried high up in the rectum by a long tube, to be retained over night and followed by copious flushing of the colon with warm water. The patient is then placed upon a proper diet. Gall-stones being composed not only of cholesterin, but also of lime and magnesia, which increase their hardness, all food rich in these substances, and particularly peas, beans and lentils, must be prohibited, and very hearty meals of any kind should be avoided. Alcoholic beverages should be partaken of very sparingly, and the bowels kept extremely regular by sulphate of magnesia, phosphate of soda, or a rhubarb-and-aloes pill. In addition, the patient should take twice a day half a pint of hot Carlsbad Schlossbrunnen or a teaspoonful of Carlsbad Sprudel salts in half a pint of hot water. As to massage of the gall-bladder, recommended by some, Dr. Weber said that a glance at the anatomy and situation of the viscus and the ducts ought to suffice to stigmatize any such procedure as injudicious and fraught with mischief. He described five classes of chronic cases which had come under his observation. The first was as follows: Cases of solitary or a few large calculi in the gall-bladder, without enlargement of the latter and without icterus, but accompanied by approaching cachexia and steadily failing health. The diagnosis is very difficult and medical treatment of no avail. In conclusion he said he was by no means of the opinion that, after the surgeon has operated and the patient made a good recovery, everything needful has been done. The gall-bladder, when not excised, is certainly not normal, nor is the bile the physiological liquid it ought to be. What holds good in the medical treatment for chronic cases without operation will hold good for those which have been operated upon.

The Domain of Medical Treatment Circumscribed.—Dr. Herbert F. Williams said that the domain of medical treatment becomes circumscribed after the development of the true cholelithitic condition, that is, after the formation of calculi. The true and efficient field for medical therapeutics is that in which we seek to combat the various conditions which culminate in such formation. Where calculi, after having become impacted in the common duct, have escaped into the duodenum, the forced dilatation of the duct seems to prepare the individual for subsequent formations which will not create the disturbance of the initial attack. Of course, all measures of treatment are primarily directed to the removal of the concretions, wherever located, and, fortunately, the increasing caliber of the branches of the hepatic duct is a constant equation in preventing permanent arrest in that duct or the longer radicles. Sooner or later concretions find their way into the gall-bladder, where they may either remain undetected and innocuous, or accumulation or concentric enlargement, together with infection through the common duct, may give rise to irritation, ulceration and perforation. When obstruction is not complete we can accomplish something by hepatic elimination, solvents and hepatic massage. Indeed, the most effective hepatic massage is the reflex and frequently violent vomiting concurrent with hepatic colic. As to measures to assist in expulsion of calculi (which expulsion, even if by surgical means, develops the opportunity for subsequent medical treatment), anodynes, whether given by mouth, inhalation, or hypodermically, not only relieve pain, but produce a relaxation of the walls of the duct; and in this way facilitate the removal of the obstructing mass. The greatest caution, however, is necessary in the administration of anodynes, lest after the attack is over alarming or fatal narcosis may result. Counter-irritation by means of a blister over the seat of obstruction will relieve the recent congestion, thus gaining a little in the lumen of the canal. We can now gently stimulate the biliary secretion, and one of the best agents for this purpose is blue flag (iris versicolor). In conclusion Dr. Williams spoke of the necessity of diet regulation and the exhibition of alkaline waters or their salts, among which sodium phosphate stood preëminent.

Indications for Surgical Interference.—Dr. A. A. Berg, in speaking on this topic, said that as long as there is no febrile complication present, surgical interference is rarely called for. When there is fever we know that a virulent organism has been introduced, setting up a violent cholecystitis. When the acute condition subsides into a chronic one the bacteria remain, and, as a result, we are likely to have contracted gall-bladder, strictures of the ducts, hepatic abscess, peritoneal adhesions, etc. Usually these patients pass into a chronic septic condition, and if handed over to the surgeon make very poor subjects; sometimes collapsing on the table. The time for operation is not during a first attack, but in the succeeding interval, when the patient's vitality is still unimpaired.

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LXXIX. NEW YORK, SATURDAY, NOVEMBER 16, 1901. NO. 20.

SPECIAL ARTICLE.

THE MAKING OF A MODERN MEDICAL SCHOOL: A SKETCH OF RUSH MEDICAL COLLEGE.

BY JOHN EDWIN RHODES, A.M., M.D.,

OF CHICAGO;

HISTORIAN AND ASSOCIATE PROFESSOR IN DISEASES OF THE CHEST, THROAT, AND NOSE, RUSH MEDICAL COLLEGE.

"WE believe the school we this day open is destined to rank among the permanent institutions of the State. It will pass in time into other and better hands; it will live on, identified with the interests of a great and prosperous city." With these prophetic words did Daniel Brainard, the founder of the college, close his introductory address at its first session, December 4, 1843.[1]

With a population in Chicago of less than eight thousand, but with a vast outlying territory of small but rapidly growing communities, where the physician was needed, but where remuneration for services was small, the hour was ripe for just such an institution as Rush in its infancy; the seed had been planted, the growth was to develop in the coming years.

The times demanded little then. The first session was of but sixteen weeks' duration, no preliminary requirements were expected save that the candidate should be twenty-one years old and of good moral character. For graduation there were required two years' attendance upon lectures (two years of practice were accepted in lieu of one course), largely repeated from year to year, three years' study with a reputable physician, and the presentation of a thesis on some medical subject. A faculty of four delivered the first course of lectures; James V. Z. Blaney being the Professor of Chemistry and Materia Medica; John McLean of Jackson, Michigan, the Professor of Theory and Practice of Medicine; M. L. Knapp of Waynesville, Illinois, Professor of Obstetrics and Diseases of Women and Children, Dr. Brainard heading the list as Professor of Anatomy and Surgery.

Dr. Brainard from the day of his arrival in the city of Chicago in the fall of 1836, until his death, October 10, 1866, occupied an exalted position in this western country. Coming from a family of educated people, he was afforded the best education that the times could supply, and having received a good common school and academic training, he at once began his medical studies and developed a studious habit thus early in his career. Two years with a preceptor in Whitesboro, N. Y., a year at a medical college in New York City, and another year in Jefferson Medical College in 1834 completed his preparation. Then teaching for two years, Latin and French were acquired in his leisure hours. Two years in Paris in 1839 and 1840 added greatly to his knowledge from the advantages for study and observation there afforded. A course of lectures on anatomy was delivered at the University of St. Louis, to the chair of which he was elected in 1842. From the time of the opening of Rush College until his death he served it with pre-eminent ability. He was noted for his eloquence in the lecture-room and on the platform, and was distinguished as an operator and original investigator. His experimental work on the use of iodine in surgery and on bone repair made him famous He received deserved recognition during his lifetime, and, while easily the most commanding figure in medicine and surgery in this great northwest, he should be classed among the most eminent men of his time in American medical history.

The line of succession as presidents of the college following his death includes the names of James V. Z. Blaney from 1866 to 1871, and Joseph W. Freer, 1871 to 1877. Dr. Freer was a graduate of the college in 1849, and almost immediately began medical teaching, devoting the remaining years of his life to the teaching of physiology, surgical pathology and histology. He was a man of fine character and quick perception. Dignified and undemonstrative, he was a superior teacher who left his impress upon students as one who knew, and had the faculty of imparting to others that knowledge.

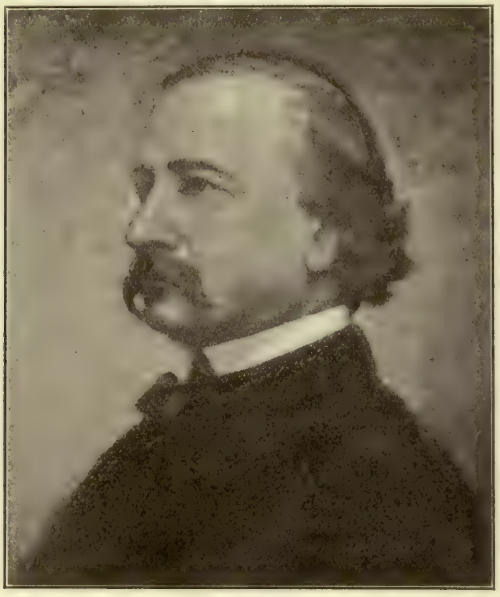
Following in the line of seniority in the faculty, Jonathan Adams Allen became president in 1877 and continued in that office until his death in 1890. In the days, not long since closed, when medicine was taught in our colleges largely by lectures, Dr. Allen will be remembered as a unique character, and one who fulfilled in large degree the requirements of such a position. With a mind well stored from ancient and modern literature, with an overflowing fund of anecdote, a ready wit and a fine command of language, he taught the truths of medicine in such forceful terms that in many a perplexing situation his students recalled the epigram and its lesson to the saving of the situation and their own reputations as physicians.

Edward L. Holmes, who had been a teacher in the college since 1870, next assumed the presidency, being chosen from seniority in the faculty, and occupying that position from 1890 until the affiliation with the University of Chicago, when the office was abolished. Closely identified with the college for a period of thirty years, with hopefulness and patience he advocated the higher

[1] The charter was granted by the Legislature of the State of Illinois in 1837, and was the first granted to an educational institution in the State.

education in medicine, hailing with satisfaction every forward step in the college, devoted to its interests with singleness of heart and with an unyielding purpose that it should stand for the best. Many of his ideals have been realized.

None of the men who were identified with the college during these eventful years deserved greater praise than Ephraim Ingals who



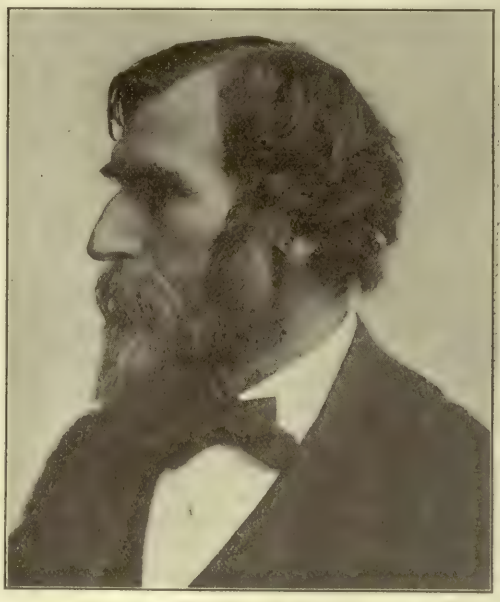
Daniel Brainard, M.D.

quietly passed away, Dec. 18, 1900, secure in the belief that his life's work was ended, and that he had earned the restfulness of the long sleep. A student of Dr. Brainard, graduated from the college in 1847, he became a professor of materia medica in 1859. In days of disaster he never faltered, in days of prosperity he longed for higher achievements. When Dr. Brainard died, and ruin seemed to menace like a grim specter the future of Rush College, he was one whose faith was sublime in the ultimate success of their efforts. He lived to see the high accomplishments of these late years.

Wm. H. Byford who was called to the professorship in obstetrics and diseases of women and children in 1859, and subsequently, in 1879, to the chair of gynecology, remaining thereafter on the faculty until his death May 20, 1890, was a grand man. Without early advantages in education, he was one of those men of sterling worth whose careers are carved out by individual effort, favored perhaps by the stress and circumstance of poverty and limited opportunities. A man of vigorous intellect, courtliness of manner, of gentle and kindly nature, he endeared himself to all. One of the fathers of gynecology he helped to place it on a plane of high excellence as a specialty. He was founder of the Woman's Medical College of Chicago, and president of its faculty and board of trustees till his death. His first contribution to medical literature in 1847 was a report of two Cæsarian sections performed by himself. He wrote the first book issued by a Chicago medical author, in 1864, a Treatise on Chronic Inflammations and Displacements of the Unimpregnated Uterus. His early advocacy of the use of ergot in the treatment of fibroids, in 1872, attracted wide attention. Many other contributions to the literature of medicine gave him rank among the best of those devoted to the treatment of diseases of women.

Another of the men who came to the college in her early history, and who had much to do with her name and fame was DeLaskie Miller, known and loved by every alumnus who listened to him from 1859 to 1889—thirty years of continuous service as her professor of obstetrics and diseases of women and children. He was eminently fitted for teaching, and his refinement of manner, courteous treatment of his pupils and delightful personality endeared him especially to his students to whom his lectures were ever a source of sincere pleasure and profit. Though retired from participation in the teaching of medicine, he still lives at the age of eighty-three years, actively devoted to the interests of the school, as president of her board of trustees.

It would be interesting to note the faculty changes from year to year necessitated by the gradual enlargement of the scope of medical teaching; so too would be of interest the mention of the many self-sacrificing, earnest and



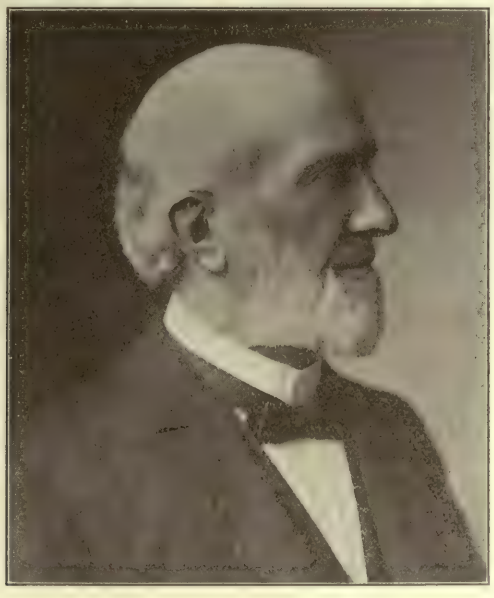
Edward L. Holmes, M.D.

faithful men who have made the college what it is to-day, and have counted no sacrifice too great for the growing demands for better facilities and higher learning in medical education, but the limitation of this article will not permit it.

In a little wooden building of two stories, now 49 Clark Street, was the office of Dr. Brainard,

and at the rear of the building was a little shed attached. This was the first Rush Medical College building. In the shed dissecting was carried on, and in the building twenty-two students sat upon rude benches to listen to the lectures of the four professors for the sixteen required weeks, and at the end of the session one man from the class received the first diploma of the college in course, two practitioners receiving at the same time the honorary degree of M.D.

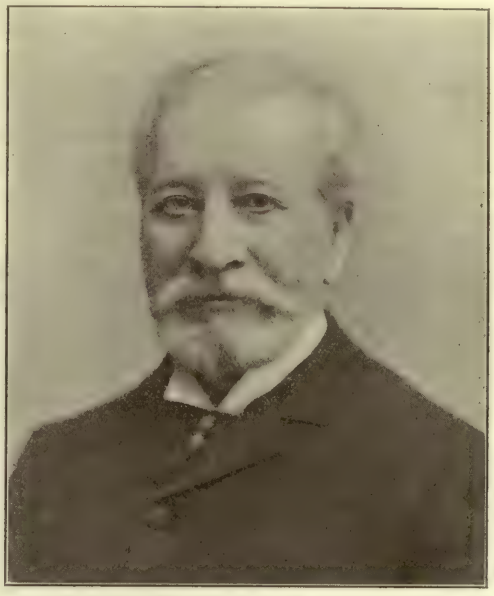
Following the first commencement there was erected in the summer of 1844, at the southeast corner of Indiana and Dearborn Streets, a one-story wooden structure at a cost of $3,500. In this building was an amphitheater, dissecting-room, and a chemical laboratory. The first course in chemistry had been theoretical only, owing to the lack of laboratory facilities Forty-six students attended this course, and at the end of the year there were eleven graduates. For eleven years this structure proved fully adequate to the requirements of the college. In this building Austin Flint, whose name and fame became familiar in later years to every medical man in the country, and whom the world delighted to honor, gave a course of lectures on the Institutes and Practice of Medicine. In 1855 it was found necessary to rebuild and enlarge the building; this was done at an expense of about $15,000. This structure provided well for two hundred and fifty students. The bonds



Ephraim Ingals, M.D.

which were issued to provide the necessary means were largely taken by members of the faculty. Twelve years later (1867) the corner-stone of another addition to the college building was laid, and it was soon completed. In this building were two amphitheaters, one above the other, the upper one seating six hundred and twenty students. Adequate provisions were also made for dissecting and chemistry, but the main feature was this amphitheater to provide for lectures to large classes, the entire matriculated body listening to them from the beginning of their course.

In 1871 came the appalling disaster to our city. The usual course had begun under favorable conditions when, on the night of October



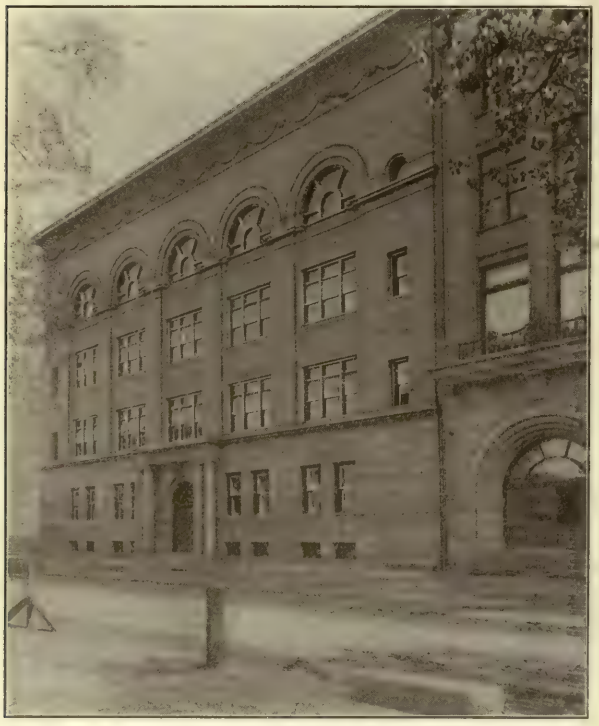
De Laskie Miller, M.D.

9th, the fire-fiend swept like a besom of destruction over the city, and in a few hours the college property was a smoking mass of ruins—a vacant lot, heavily mortgaged, was all that was left; the personal property was swept away; students and faculty were scattered, many of them deprived of homes and property. The situation was desperate, but with the incomparable courage which was demonstrated in every department of life and industry at that time, the classes were called together in a few days, lectures were resumed in the amphitheater of the Cook County Hospital, and dissecting was carried on in rooms kindly provided by the Chicago Medical College. Fortunately rare opportunities were thus afforded the classes for clinical instruction in this use of the Hospital.

Realizing the advantages to be derived from the vast clinical material that the future would offer at the County Hospital, the time seemed opportune for locating in close proximity to that institution. The old hospital building was fast becoming inadequate to the demands of the public and, until a new site was selected, it was deemed good policy to be contented with temporary quarters. Therefore the famous college "under the sidewalk" was supplied. It was a poor and mean structure, of unplastered brick, largely below the street level, but it contained an amphitheater and a chemical laboratory and a dissecting-room. The writer, then a college-stu-

dent, remembers distinctly the impression made by the immaculate Prof. Gunn, before the days of antisepsis, as he appeared in the arena in this building in Prince Albert coat, light trousers, polished shoes and linen to match, as if dressed for an afternoon reception, performing his brilliant operations before a class of eager spectators, with results, too, that could afford little room for criticism of methods. He was not only a great surgeon but a teacher of rare excellence.

The present permanent location was selected diagonally opposite the site of the new County Hospital. Here in 1875 and 1876 was built the structure substantially as it is to-day. The cost of the lot and ground, $75,000, was subscribed by the faculty almost entirely, bonds being furnished for such subscriptions. Prof. Allen delivered the address, and also that at the opening



Laboratory Building.

of the college in the new building at the beginning of the following year.

With the development of the laboratory idea in the teaching of the science of medicine came demands for enlarged laboratory facilities, so that in 1893 on a lot opposite the college structure was erected a five-story building with a frontage of 100 feet to be devoted entirely to laboratory and recitation work. This provided also a large, light room on the top floor, with cemented floors and walls, iron and glass tables, and every modern convenience for anatomical work. During the present year another building (to cost $112,000) is being erected with money given by the faculty. It has been named the Nicholas Senn Hall, in honor of the eminent surgeon and devoted teacher whose generosity made it possible. The building, which is being rapidly pushed to completion, covers a ground space of 40x90 feet, and is seven stories high. The basement and first three floors are to be utilized for a free dispensary, the fourth and fifth floors for clinical laboratories and recitation-rooms, the upper floors for surgical and medical amphitheaters, while the college library will occupy a room fitted to its rapidly increasing equipment on the lower floor of the old building. This much for the evolution of equipment, for the making of a modern medical college.

Possibly a brief sketch of the outgrowth of educational methods can be conveyed in a short résumé of what has been taught in the college, beginning with the faculty of four. In 1843 the essentials were theory and practice of medicine, anatomy and surgery, chemistry and materia medica, obstetrics and diseases of women and children. Who shall say, when the men and the methods of those days are reviewed, that they did not serve well and successfully their day and generation? With the following year came additions to the faculty, the separation of anatomy and surgery, the combination of materia medica and therapeutics, and chemistry and pharmacy were united. In the announcement for 1845 is made, to students of to-day, the rather remarkable statement, in view of the modern equipment of a college, that a noteworthy addition to the apparatus was "a fine microscope of sufficient power to exhibit the blood-globules, spermatic animalculæ, the elementary tissues and pathological structures." Fifty-one surgical cases and operations in a year at that period does not cover a week's exhibit in the college of to-day!

As early as 1847 the college was fortunate in establishing a hospital connection, which, though small, afforded practical clinical instruction to the students.

In 1848 the establishment of a chair of physiology and pathology was announced, which was filled the following year by Prof. N. S. Davis, Sr., the "Nestor of the American Medical Association." The desirability of an extension of the course of instruction which had been given in two sessions of sixteen weeks each was becoming apparent, and a spring course of lectures of eight weeks was then given, and in the courses offered was one on auscultation and percussion by Prof. Brainard. In 1850 the hospital facilities were enlarged by utilization of the clinical material at the United States Marine Hospital, which was in the immediate neighborhood, and to whose wards the students were admitted. For the first time there was made an additional requirement for graduation, namely, "a hospital attendance of at least one term." In 1855 we find provision made for medical jurisprudence, and for comparative anatomy. The time had not fully come in 1848 for an extension of the period of study in the medical college and the spring course had been abandoned, but in 1859 the work was revived and an extra session was

again undertaken as a spring course. At this time, too, a growing difference of opinion as to the desirability of grading the courses of study came to a climax, resulting in the resignations of several members of the faculty and the establishment of another medical school in Chicago with this idea dominant. It was then, too, that Prof. Allen was called from Michigan—"Uncle Allen," the affectionate sobriquet of students in after years. There was then organized what was termed the "Preparatory School of Medicine," and the department then and later was manned by many of the younger teachers whose influence in the development of medical teaching has been and is forcefully exerted in the advancement of the present day. It was the initiative of an extended course for attendants and ear was added to the curriculum and later, in 1866, clinics at the County Hospital were announced and postmortems before the class, and in addition daily clinics at the United States Marine Hospital in surgery and diseases of the chest, and two years later a chair of clinical medicine and diseases of the chest was established. In 1868 Dr. Charles T. Parkes, a recent graduate, assumed the position of demonstrator of anatomy. For twenty-three years, until his untimely death, his service as demonstrator and professor of anatomy and professor of surgery was marked by an enthusiasm and faithfulness that left its lasting impress upon the college.

The graduating thesis, a time-honored custom in the medical school, was omitted from 1868.

Rush Medical College and Presbyterian Hospital.

of the regular session, which continued without interruption until the extension of the regular winter course in 1893 to eight months. The optional spring course, beginning with an attendance of about twenty, grew to have about two hundred and fifty before it was discontinued.

The War of the Rebellion came and with it another special field of study, military surgery, which was offered in a preliminary course by Prof. Brainard. We find also the subject of toxicology, the presentation of the surgical anatomy of special regions, and comparative anatomy of the digestive organs, added to the curriculum.

The hospital work at this time was also interrupted by the War, the City hospital being utilized by the government as an eye and ear hospital; at the close of the War the institution passed into the hands of the County.

In 1863 the subject of the diseases of the eye

There had been during these years, a gradual development in the segregation of different subjects, so we find provision made in 1872 and soon afterward for the following subjects in the spring course: principles and practice of medicine; materia medica and therapeutics; anatomy, chemistry, physiology and histology, obstetrics, toxicology and medical jurisprudence, pathology, microscopic anatomy, and the use of the microscope (for many years, however, this subject received but perfunctory attention), diseases of the eye and ear, diseases of the brain and nervous system, diseases of women and children, dermatology and syphilis, and diseases of the chest and physical diagnosis. Thus, for many years, the spring course, furnished, at the hands of young and selected men a résumé of the entire subject of medicine as then taught. A *concours* was held for the selection of teachers for this

course. Each candidate was required to appear on a certain evening in the presence of the faculty and students and lecture for at least twenty minutes on some topic selected either by himself, or by lot. The selection from merit as a lecturer well illustrates the importance attached to facility as a public speaker at this period in medical teaching. The candidates who delivered the best lectures were selected in this *concours*. From these men, in the spring courses, there were constant promotions to the regular staff, and while the course was entirely separate from that given in the winter the selection of it by a large number of the students from year to year was evidence of the necessity that would in time lengthen the regular winter course.

The clinical work had, except in the department of surgery, up to 1877, been done in the dispensary and in the hospitals open to the college students. At that time there were instituted in the college building clinics on diseases of the nervous system; on diseases of the heart and lungs, and medicine; and soon after on skin and venereal diseases. Since that day these clinics, added to and with some changes, have been maintained weekly throughout the year, this method of teaching having met the demand for more practical work. Soon were added clinics in diseases of children, gynecology, diseases of the eye and ear, and in 1884 a clinic on the then new specialty of diseases of the throat and nose. The surgical clinics, also, about this time, were increased to two a week and in 1890 to three a week. These clinics were supplied with ample material for many years from the Free Dispensary connected with the college.

In 1883, on a lot adjacent to the college building, the college began the erection of a hospital with a single contribution by a relative of Prof. Ross, and others by members of the faculty. After $25,000 had been expended, it was deeded to an association in the interest of the Presbyterian denomination, and from it has grown the great Presbyterian Hospital, by agreement attended largely by the faculty of the college. Since its addition to the clinical facilities there have been maintained surgical and gynecological clinics that would vie with the largest in the world in the wealth and variety of material offered, and the contributions to the other clinics have been of increasing value. In obstetrics it affords the students personal contact with cases.

We have now come down to the later years when changes have come with startling rapidity. We can do no better than to speak briefly of several important ones of recent date, and the present position of the college, as an example of a "modern medical school."

Recognizing as early as 1874 the value of a university alliance, the full fruition of the hopes of the faculty of the college in this particular were not realized until 1898 when Rush became affiliated with the University of Chicago. As a preliminary to this connection, the college, having a debt of $71,000, took immediate steps to pay it; $25,000 was given by Dr. E. Ingals and $25,000 by Dr. N. Senn, the remainder being contributed by various other members of the faculty, and the entire equipment was turned over to a new board of trustees, none of whom were connected with the teaching force of the college.

In reviewing the history of Rush College thus far it will be seen that the laity has contributed almost nothing to the education of its physicians in this college, although money without stint has been given to general educational institutions, and many other special ones, and to the founding and maintenance of hospitals. What is true of Rush is true of most other medical schools in America. In other words, the wealthy who demand for themselves the highest skill in their physicians have not in the West, and not until recently in the East, contributed of their affluence to make them so. Why should not medicine now be the recipient of the bounty of those who desire to benefit mankind, to whom as a profession it is singularly and unselfishly devoted?

Not only was this entire equipment given by the faculty, but it entered upon a campaign of distinct advance in every line in medical education, which necessarily greatly increased the cost of instruction.

The Quarterly System.—In December, 1898, the faculty committed itself to the quarterly system, that is, the division of the academic year into quarters, instruction being given throughout the year. This permitted the entrance of students at the beginning of any quarter and graduation at the end of any quarter when all requirements have been fulfilled. Attendance is required before graduation on twelve quarters, and at least forty-five months must elapse between the date of matriculation and the date of graduation. Instruction in all departments continues throughout each quarter, or in special cases, for a single term, that is, half of a quarter.

The experience of two years has amply demonstrated the wisdom of this arrangement for the following reasons: The expensive equipment is in use throughout the year; a student may begin the study of medicine at the opening of any quarter; special course students may avail themselves of the summer quarter, this season appealing strongly to practitioners of medicine, and many find it advantageous to continue their medical studies throughout the year; others who are paying their own way often find employment more readily during the fall or winter sessions; clinical material is usually abundant in the summer quarter; it favors the concentration of courses, as it has been found much more conducive to the mastery of a subject to have it presented frequently over a short period of time, rather than but once or twice a week throughout the year, as was formerly the custom; and finally, it lends itself admirably to the systematizing and grading of courses. Perhaps one of the most advantageous features of the quarterly sys-

tem is its stimulation of all members of the faculty to do their very best work. By it the younger members, especially the assistant professors and instructors, have quite as good an opportunity to demonstrate their teaching qualities as the older professors, thus inciting to the best work in every department.

The Elective System.—Another advanced step was taken July 1, 1899, namely, a number of courses in the junior and senior years were made elective, the student being allowed to select from the list of elective courses a number, including both required and elective studies sufficient to insure him credit for about twelve majors a year.[1]

All the courses now offered in the junior and senior years are elective. Practical experience has already demonstrated that a student can, under certain restrictions, better average his work and follow out special inclinations adapted to his tastes, abilities, and needs under this system. A new spirit has seemed to prevail in the faculty and there is found an infectious emulation prevalent which means that it is understood that good work counts and subjects poorly taught are likely to be neglected by a discriminating student body. With the spirit of reform in medical instruction, has come in this school a rapid advance in preliminary requirements, so that preparation for admission must now cover a period of four years in a secondary school (high school or academy) of high grade, from which specific credits are exacted in each subject. For the sessions of 1902-3 and 1903-4 the student must present a certificate of admission to the sophomore class in an institution of equal rank with the University of Chicago. For the session 1904-5 a student must be prepared to enter the junior class.

Transfer of the Freshman and Sophomore Classes to the University.—In utilizing its University connection a radical step has just been taken in the separation of what may be termed the purely scientific or preclinical from the practical or applied scientific study of medicine. The art of medicine, it is hoped, may in the near future be better taught by an additional year of work in a hospital before a diploma is awarded. The University, magnificently equipped for the work, offers instruction in the following branches, covering the freshman and sophomore years of the medical college: Anatomy, gross and microscopic; neurology, embryology, physiology, physiological chemistry, inorganic, organic, and analytical chemistry, toxicology, pathology, bacteriology, and pharmacology. These two classes will be taught at the University, while the work of the third and fourth years only will be done entirely at the medical school. With this transference of the work has come the admission of women to the courses of the first two years, following out the established policy of the University in the co-education of the sexes. Ten years' experience has amply demonstrated the wisdom of that policy. Its adoption for the final two years of the medical course has been successful elsewhere; why should it not be, even in a greater degree, in Rush College?

In sketching thus roughly the making of a modern medical college, one can but be astounded, in comparing the school of only half a century ago with the school of to-day, at the remarkable advancement of medicine, especially during the closing decade of the nineteenth century. The fact is evident that the forward march in educational methods everywhere in this country finds in its vanguard the medical profession, now, as ever, unsatisfied with the achievements of the past, pressing still onward and upward in their dedication "to the quest of knowledge that may lessen pain and prolong life."

34 Washington Street.

[1] A major course is defined as a didactic or recitation course, occupying five hours a week for one quarter (a total of sixty hours), or a laboratory, practical, or clinical course occupying ten hours a week for one quarter (a total of one hundred and twenty hours). A minor course is a didactic or recitation course occupying five hours a week for six weeks, or a laboratory course occupying ten hours per week for a similar period.

ORIGINAL ARTICLES.

ON THE NATURE OF THE PROCESS OF FERTILIZATION.[1]

BY WILLIAM J. GIES, M.S., PH.D.,
OF NEW YORK;
INSTRUCTOR OF PHYSIOLOGICAL CHEMISTRY IN COLUMBIA UNIVERSITY.

SINCE the time of Leeuwenhoek and his pupils (1677) it has been known that the fluid secreted by the male generative organs contains spermatozoa. The earlier observers noted the active movement of these innumerable minute bodies in the fresh fluid and assumed them to be parasitic animalcules, "sperm animals." A century later, about 1786, Spallanzani demonstrated that the fertilizing power of the semen is possessed by the spermatozoa and not by the liquid portion, since the semen loses its potency when the spermatozoa are separated from it by filtration. Kölliker, in 1841, proved that the spermatozoa are formed from the cells of the testis and, therefore, are not parasites as the earliest observers had assumed, but, like the ova, are derived directly from the parent-body. In 1865, Schweigger-Seidel and La Valette St. George showed that the spermatozoön, like the ovum, is a peculiarly-modified single cell of extraordinary minuteness, containing a nucleus and cytoplasm, and on the whole morphologically equivalent to other cells. In 1875, O. Hertwig established the fact that normal fertilization of the ovum is brought about by immediate union with but one spermatozoön.

Although Leeuwenhoek had assumed that the spermatozoa must penetrate the ova in order to effect proliferation, nearly two centuries passed before the fusion process was actually observed.

[1] The substance of this paper was given by the author at a recent meeting of the Society of Physiological Chemists, New York City.

It was first described in detail by Fol in 1879. "In every known case an essential phenomenon of fertilization is the union of a sperm-nucleus, of paternal origin, with an egg-nucleus, of maternal origin, to form the primary nucleus of the embryo."

The exact nature of the process which causes proliferation of the fertilized egg is not yet understood. During the past few years important additions to the facts bearing on this question have been made by Loeb, whose well known studies of the mechanics of life phenomena have not only added greatly to our exact knowledge of biological events, but, also, have shown the important influence which the modern physico-chemical theories may have upon our understanding of animal functions.

Loeb had come to the conclusion, as a result of numerous and varied experiments, that "something in the constitution of the sea-water prevented the unfertilized eggs of marine animals from developing parthenogenetically." It had been known for some time that the unfertilized ova of arthropods, echinoderms and worms segment into a few cells (2-4) when left for a comparatively long time in sea-water, but this was generally considered a pathological phenomenon. In his earlier experiments Loeb kept *unfertilized* eggs of a common species of sea-urchin for two hours in sea-water whose osmotic pressure was slightly increased by the addition of various electrolytes. When the eggs were returned to normal sea-water they soon began to segment, and blastulæ, gastrulæ and plutei, which appeared to be normal in every respect, rapidly developed. In brief, the general effect in the production of the embryo was apparently the same as that ordinarily caused by spermatozoa. These same results have been obtained by Loeb with the eggs of other animals and have been verified repeatedly by other observers, including the author.

In one of his first communications of the results of the work just referred to, Loeb says: "From these experiments it follows that the unfertilized egg of the sea-urchin contains all the essential elements for the production of a perfect pluteus. The only reason that prevents the sea-urchin from developing parthenogenetically under normal conditions is the constitution of the sea-water. The latter either lacks the presence of a sufficient amount of the ions that are necessary for the mechanics of cell division (Mg, K, OH or others) or it contains too large a quantity of ions that are unfavorable to this process (Ca, Na or others), or both. All the spermatozoön *needs* to carry into the egg for the process of fertilization are ions to supplement the lack of the one or counteract the effects of the other class of ions in the sea-water or both. The spermatozoön *may*, however, carry in addition a number of enzymes or other material. The ions and not the nucleins in the spermatozoön are essential to the process of fertilization. . . . I consider it possible that only the ions of the blood prevent the parthenogenetic origin of embryos in mammalians and I think it further not impossible that a transitory change in the ions of the blood may also allow complete parthenogenesis in mammalians."

At a somewhat later period in his work on marine animals, Loeb stated: "The spermatozoön not only starts the development of non-parthenogenetic eggs, but it is also the bearer of the hereditary qualities of the male. From our experiments it becomes evident that these two functions of the spermatozoön are not necessarily bound together, for nobody would assume for an instant that the hereditary qualities that are carried by the spermatozoön could be imparted to the egg by a change in the inorganic constituents of the sea-water. We have learned to attribute the different activities of a cell to different enzymes. We must in future consider the possible or probable separation of the fertilizing qualities of the spermatozoön from the transmission of hereditary qualities through the same. . . . The bulk of our protoplasm consists of proteid. . . . The proteids are characterized by two qualities which are of the utmost importance in the analysis of life phenomena. The proteids change their state very easily, and readily take up or lose water. . . . The agencies which affect these two variable qualities of the protoplasm most powerfully are, first of all, certain enzymes. . . . Almost equally powerful are ions in certain concentrations. . . . The third agency is temperature. In our experiments it was evidently the second factor which affected the condition of the colloids." The latter sentence refers, naturally, to the colloids of the ovum.

Subsequent experiments on sea-urchins enabled Loeb to give a more definite answer to the question of the nature of the process of fertilization. He found that an increase in the osmotic pressure of the sea-water through the addition of cane sugar or urea can produce parthenogenesis. *"This proves conclusively,"* says Loeb, *"that the development of the unfertilized egg is produced through an increase in the concentration of the surrounding solution. As it is immaterial whether the increase in the osmotic pressure is brought about by electrolytes or non-conductors, there can be no doubt that the essential feature in this increase in the osmotic pressure of the surrounding solution is a loss of a certain amount of water on the part of the egg.* . . . . A consequence of the loss of water on the part of the egg is an increase in its osmotic pressure. The osmotic pressure inside the egg is furnished chiefly or almost exclusively by electrolytes. It is thus not impossible that the ions in the egg, if their concentration is raised, bring about that change which causes the egg to develop. If we assume that the spermatozoön starts the development of the egg in the same way as in the case of artificial parthenogenesis, it follows that the spermatozoön must possess more salts or a higher osmotic pressure than the eggs. . . . But there is no reason why the

spermatozoön should not bring about the same effects that we produce by reducing the amount of water in the egg, in some different way. . . . It seems as if the liquefaction of the nuclear membrane and other constituents of the nucleus were a prerequisite for cell division." Possibly this liquefaction is accomplished by enzymes.

In his last paper, after many additional experiments on marine fauna, Loeb stated that "the bridge between the phenomena of natural and artificial parthenogenesis is formed by those animals in which physical factors decide whether or not their eggs develop parthenogenetically. In plant lice parthenogenesis is the rule only as long as the temperature is high or the plant has plenty of water. If we lower the temperature or let the plant dry out, sexual reproduction occurs. The drying-out of the plant causes the tissues of the lice to lose water. The same factor, loss of water, makes the artificial parthenogenesis of echinoderms and chætopterus possible. In plant lice the effect is of the same kind, only in the opposite direction."

Further on in the same communication, Loeb adds: "The general opinion concerning the rôle of the spermatozoön in the process of fertilization is that it acts as a *stimulus,* and that as such it starts the development of the egg. . . . If we consider the fact that the eggs show at least a beginning of segmentation under 'normal' conditions, the act of fertilization assumes a different aspect. The spermatozoön can no longer be considered *the cause* or *the stimulus* for the process of development, but merely an agency which *accelerates a process that is able to start without it,* only much more slowly. Substances that accelerate chemical or physical processes which would occur without them are called catalyzers (Ostwald). According to this definition we may assume that the *spermatozoön carries a catalytic substance* into the egg, *which accelerates the process that would start anyhow but much more slowly.* . . . It would be wrong to say that *the K-ions are the stimulus* that causes the developmental process. *They merely act as catalyzers, accelerating a process that would otherwise proceed too slowly.* The loss of water on the part of the egg-cell must have a similar effect, but possibly a less direct one. It may be that the loss of water alters the chemical processes in the egg in such a way as to give rise to the formation of a substance which acts catalytically. . . . The introduction of the catalytic substances which accelerate the processes of development saves the life of the egg. This may be made intelligible on the following assumption. Two kinds of processes are going on in the mature egg after it has left the ovary. The one leads to the formation of substances which kill the egg; the other leads to the formation of substances which allow growth and cell division and are not poisonous. We may use as an illustration Pasteur's well-known experiments on the behavior of yeast cells in the presence and absence of atmospheric oxygen. In the presence of oxygen the yeast cells multiply on a sugar solution, while the zymase effect is comparatively small. In the absence of oxygen the multiplication of cells is limited or may stop, while the zymase effect becomes more prominent. The products of alcoholic fermentation are comparatively harmless for the yeast cell, and for this reason an increase in the fermentative activity of the cell does not cause the death of the yeast. I imagine that matters are similar in the mature egg-cell after it has left the ovary, with this difference, perhaps, that the substances formed (by fermentation?) in the egg-cell are more poisonous for the egg than the alcohol and the other products of fermentation are for the yeast. The process that causes the death of the egg-cell and the one that causes cell division are at least partly antagonistic. They are both inhibited by a low temperature, so that in this case death does not occur, although no cell division is possible. If we succeed in finding a substance which accelerates the process of cell division at the normal temperature, this will at the same time lead to a suppression or a reduction of the antagonistic process that shortens life. In the case of the egg of chætopterus a trace of K-ions acts as such a catalytic substance; possibly a trace of H-ions; and perhaps certain substances that are formed when the egg loses a certain amount of water. For the echinoderm egg we know at present only the last factor. In addition there are the catalytic substances carried or produced by the spermatozoön (ions? enzymes?). But there are certainly other catalytic substances, as is proved by tumors and galls, in which the variety of structures corresponds to an almost equal variety of parasites. We do not need to assume a specific parasite for each kind of tumor. Teratomata may be explained on the basis of the parthenogenetic tendency of the mammalian egg in connection with some chemical change that furnishes the catalytic substance. But it is not impossible that even in benign tumors, such as a teratoma, the catalytic substance may be due to parasitic organisms.] It is very important to realize that the introduction of catalytic substances into the egg does not prolong its life unless the egg has reached a critical point determined by two sets of conditions. The one is the maturity of the egg, the other the change of conditions connected with the egg leaving the ovary. . . . . The fact that there is an age limit for the development of carcinoma may be a similar phenomenon. The catalytic substances which are given off by the cancer parasite may not be able to bring about cell division in the epithelial cells unless the latter have reached a critical point, which is at least partly determined by the age of the individual."

Among the catalytic substances which Loeb has constantly had in mind in his brilliant observations in this connection are enzymes, as has already been indicated. With the advice and many helpful suggestions of Professor Loeb, the writer, working in Prof. Loeb's laboratory at

Wood's Holl, recently attempted to ascertain whether any experimental justification can be found for the assumption that the spermatozoön carries substance into the ovum which effects proliferation by zymolysis.

Pieri appears to have been the first to give this question experimental examination. Several years ago (1897) he reported that he had extracted soluble enzyme from the testicles of two varieties of sea-urchin, which had the power to bring about segmentation of ova of the same varieties. The enzyme, which he called "ovulase," was obtained, he said, by merely shaking the testicles in distilled water or sea-water. As he himself was not sure that all spermatozoa were killed in the extraction process, it seems certain that his results were due not to "ovulase," but to live spermatozoa.

Dubois, in 1900, arrived at the conclusion that natural fertilization comes about through the action of a fecundative ferment. He claims that he was able to separate such a body, "*d' une zymase fecundante,*" from the testicles of a variety of sea-urchin, but, unfortunately, no experiments showing its qualities or method of preparation were detailed by him. Dubois named the ferment (?) "spermase" and credited it with the power of modifying a hypothetical substance pre-existent in the ovum, which he called "ovulose."

Winkler, a little more than a year ago, reported the results of experiments similar to those of Pieri. Great care was taken to destroy the spermatozoa in the extracts and Pieri's work was much improved. The influence of the extracts was practically negative. Sometimes with the same extract the eggs of one individual "reacted," whereas the eggs of another did not. The proliferation never went beyond the 4-cell stage. It is well known that the unfertilized eggs of the sea-urchin are prone to divide into a few cells if they are allowed to remain undisturbed in normal sea-water for about a day—the usual length of Winkler's experiments. Winkler's results are hardly positive enough for the deduction that fecundative enzyme was obtained; they might, in fact, be used to show how unwarranted were Pieri's conclusions.

Shortly after Winkler's paper appeared, Cremer published a very brief note giving a general statement regarding some unfinished experiments by himself and Hofer. They worked with the testicles of trout and used the Hahn-Buchner pressure method for obtaining sperm extract. They found that none of the expressed fluids from the trout spermatozoa possessed any segmental activity on mature trout ova. No description of the experiments nor methods used in testing the extracts were given by these observers in their preliminary note.

Loeb recently made a series of experiments with various non-spermatic enzymes to determine proliferative power on the unfertilized eggs of the sea-urchin, but with negative results. He states that "the only enzyme that caused the egg to segment at all was papain," but he could not be certain that this was not due to some accidental constituent of the sample of the enzyme used. "The other enzymes were absolutely without effect."

Two years ago Mathews, in some unpublished experiments cited by Loeb, tried the effect of rennin (rennet tablets) on unfertilized eggs of the sea-urchin. Segmentation into a comparatively small number of cells resulted. Mathews concluded, however, that the results noted had been produced not by the enzyme, but by the salts in the tablets increasing the concentration of the water.

Up to the time, then, that the author's work was begun it seemed possible that enzyme action might be a causative influence in normal segmentation of the ovum after introduction of spermatozoön, but no definite experimental evidence had been presented to support the theory.

Regarding the writer's work a multitude of details may be passed over and the essential facts regarding methods of procedure, etc., stated in the following brief account:

Because of the ease with which large quantities of the spermatozoa and ova of the common sea-urchin can be obtained, we used the sexual organs of this marine animal, which has furnished the material for many classical studies of cell development. The normal conditions under which fertilization and proliferation of the ova of the sea-urchin occur can be easily maintained in sea-water in the laboratory. Many of the usual methods of enzyme extraction were employed on the testicles. The eggs, always normal and mature, were kept in ordinary sea-water to which various quantities of sperm extract were added. Careful examination of the eggs was made at frequent intervals during twenty-four hours. Concentration of the sea-water was entirely prevented. The results of twenty-eight series of three to thirteen twenty-four-hour experiments were entirely negative—that is, no proliferation resulted and every extract was devoid of segmental power. Control experiments were made with each series, which showed that normal conditions prevailed and that the eggs would have segmented had the extract possessed proliferative power. It was also ascertained in control experiments that the extracts were devoid of toxic property.

The persistently negative results of these experiments, in which the existence of neither an enzyme nor a zymogen could be indicated, gradually led me to believe that possibly an enzyme is formed from material in the egg, or in the sperm, or in both, on contact of the two living elements. If such were really the case it would seem that extracts of the eggs which had been normally fertilized might, under appropriate conditions, possess the power of inducing segmentation of unfertilized ova.

A large number of eggs in sea-water were accordingly treated with a drop of spermatic fluid and allowed to develop in the normal manner to

various stages—in one experiment as far as the blastula stage—when the fluid was separated by decantation, the cell-groups thoroughly ground in a mortar with sand and extracted in several of the usual ways for the isolation of enzymes. None of these extracts had any power of causing fresh mature eggs to segment.

Entirely negative results rarely justify sweeping deductions. Since enzymes are indiffusible, or, at most, are only very slightly diffusible, it is possible that in experiments of the kind conducted by Loeb, Mathews, Winkler, Pieri, Cremer and myself, enzymes which may be contained in the extract does not and cannot enter the substance of the ovum, yet it may be that direct absorption of such enzyme in solution could take place through the micropyle. It may be that sperm enzyme, if such really exists, is as intimately connected with the structural elements of the cell, and as resistant to extraction processes, as Fischer has found the inverting ferment of the mould *Monilia candida* to be. But even if it is extractable, it might be assumed, with reason, that mere contact of the ovum with enzyme in solution would not cause segmentation and that, even if the peripheral portions of the cytoplasm should be directly affected by such immersion, the general effect would be entirely different if contact, or diffusion, occurred within the substance farther toward the nucleus. Possibly the morphological character of the spermatozoön, specially adapted as it is for great motility and penetration, should imply that segmentation by indiffusible enzyme contained in fluid surrounding the ovum is no more possible in artificial than it is a part of normal fecundation. If it is ever found that spermatic enzyme, or zymogens, are causative influences in natural fertilization, I venture to predict, in view of the results of our experiments, that their action will also be shown to depend on their direct delivery to points *within* the ovum.

If ions are to be reckoned among the agents of proliferation, why, it may be asked, did they not make active the sperm extracts used in these experiments? Unfortunately, we know nothing at present of the proportion of *dissociated* electrolytes in the spermatozoön and in such extracts. The composition of the ash does not furnish an accurate idea of the amount in the spermatozoön of salts pre-existent as salts and *dissociable* in extracts, although the comparatively large quantity of ash in spermatozoa, as found by Hammarsten and others, may suggest proportionately large quantity of dissociable electrolyte. We know little of the relative proportion of the various constituents of spermatozoa and ova, and we have no knowledge of the absolute or relative quantity of free *ions* entering or acting within the ovum. The ions which become active in the ovum may be originally a part of the molecules of the proteid compounds of the ovum, or of the sperm, or of both until the spermatozoön mingles with the protoplasm of the ovum and forms new and probably simpler combinations. The writer's experiments were neither intended for, nor were their conditions suited to an investigation of this particular phase of the fertilization problem. The results cannot, therefore, be interpreted as having any bearing on them.

Summing up briefly, the chief experimental results of our work are:

1. Extracts of the spermatozoa of the sea-urchin, which have been made by the ordinary methods for the preparation of enzyme solutions, do not possess any power of causing proliferation of the ripe ovum.

2. No evidence could be furnished of the existence of a zymogen in spermatozoa.

3. Extracts of fertilized eggs, in the earlier stages of development, were likewise entirely devoid of segmental activity.

4. Enzyme seems to be excluded from the catalytic substances which Loeb and others have thought may influence the initial divisions of the ovum after the introduction of the spermatozoön, although it is possible that the conditions of these and previous experiments were unfavorable to the manifestation of activity on the part of fecundative ferment. It seems more probable, however, that Loeb's theory of the influence of spermatic *ions* in fertilization affords the true explanation of the phenomena in question.

INFANTILE PLEURISY WITH EFFUSION.

BY W. T. ENGLISH, M.D.,
OF PITTSBURG, PA.

THERE are few diseases in which the diagnostician is more frequently at fault than in pleurisy with effusion in the infant, the most common error being to confound it with pneumonia. To examine the infantile thorax intelligently presupposes a special knowledge of its peculiar anatomy, and the incidental modifications in size, shape, location and mobility of parts and organs.

Experience, which is a stepping-stone to confidence, leads, under most conditions, to commendable misgiving in the presence of infantile pleurisy with effusion. Cocksureness in discriminations involving pleuritic effusion and pneumonia belong only to those who have not yet been sublimated by the noble tutelage of recognized error. The dubious frame of mind prompts to careful scrutiny and permits no opportunity for re-examination to pass unimproved so long as the responsibility continues, and is therefore the better condition. After a few experiences with these maladies in the infant, physicians avoid comparisons with the clinical pictures of the diseases as presented by adult cases.

There are many difficulties in the way of a thorough physical examination of the baby thorax. The pose and covering favorable to best results are almost never realized. Needful quiescence is wanting, and, because of the small area of the infant thorax, the employment of the immediate methods of auscultation and percussion are precluded, or are rendered of little service. Persisting in the immediate methods of

FIG. 1.—Showing the drooping of shoulder and anterior deformity fourteen years after expulsion of pus from pleura.

percussion, the laying on of heavy hands awakens a resistance through the external sense of feeling and brings about a tissue tension which changes the residing note. The application of the side of the head to the child's thorax brings in play the sound conducting power of the head bones, and the audible phenomena belonging to the entire side are thus made confusing.

If a case of infantile pleurisy with effusion be investigated systematically, the history of chilliness, if secured at all, will be found to have exhibited an intensity, ranging from slight chill to severe rigor. A casual glance at the fever chart of forty-eight hours will betray extensive excursions, and even suggest septic processes. The fever is irregular and remittent. The pulse, always without rhyme or reason until the period of puberty, sustains its reputation. Pain cannot be definitely located, but is intimated in a pantomimic way and given a very vague abiding-place. The visualizing analysis of inspection loses its value as a means of differentiating pleurisy with effusion from pneumonia, as loss of mobility is common to both; and again the respiratory experience of the infant chest is too limited to be trustworthy. Flattening of the intercostals or distention is duly observed in a few cases, but flattening is rarely appreciable, and fluid sufficient to cause bulging does not often accumulate in the infant thorax.

Displacement of the heart-beat is seldom demonstrable in the extreme young, but if it can be it merits attention. This sign is most valuable in left-sided effusions. Vocal fremitus is not often observed in the infant chest, and the respirations are accelerated in proportion to the neurosal conditions rather than with the pressure of the fluid. Neurosal symptoms are emphasized to the degree of epileptiform seizures and the ultimate manifestations in the presence of purulent effusions have been those of meningitis. The respiratory action should be estimated during slumber or in quiescent wakeful periods.

The auditory phenomenon which may also appeal to touch—friction—is not intensely developed, and, when present, is evanescent and must be found without delay, or it will evade detection.

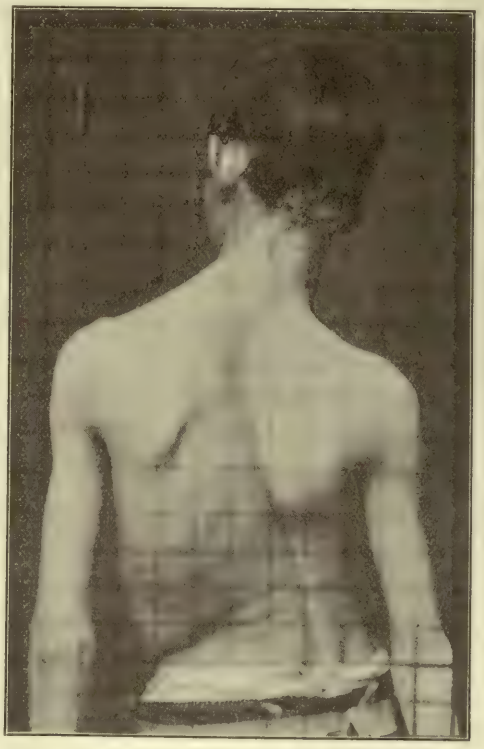

FIG. 2.—Showing posterior deformity fourteen years after expulsion of pus from pleura.

Influencing all auditory phenomena is the peculiar subtympanitic note residing in the child's thorax. Immediately over, as well as around the fluid within the pleura, percussion may secure a clear sound. Flatness belongs to massive effusions, and the tone elicited is a compromise between the tympanitic and the dull note. In using the light stroke, the tactile sense of resistance is sacrificed. The heavy stroke delivered upon the

thorax of the infant would awaken a response from the abdomen or stomach. An important fact often overlooked is the purely physical one, that fluid is a good conductor of sound, provided the sound be properly transmitted and through material which has good conducting qualities. The air vesicles are not good transmitters and so long as these intervene between the bronchial tubes and the fluid, the tubular sounds cannot travel. However, only a meager amount of fluid is required to collapse the infantile alveoli and produce atelectasis. The tubes continue some time thereafter to maintain their lumen and resist the pressure. These conditions impart to the percussion note dulness instead of flatness, modify tactile and vocal fremitus, contribute bronchophony, transmit bronchial râles and crepitations, thus sustaining the delusion of pneumonia. The clicking of coins upon the infantile pleuritic effusion is transmitted much better through the fluid than over the normal vesicular lung structure. If the circumscribed area be delineated, it will not be discovered necessarily in the lower portion of the chest, but may appear encysted in other localities. Adhesions may so

Fig. 3.—Showing contraction of diseased side fourteen years after expulsion of pus from pleura.

perfectly surround it that change in position has no effect upon it. It is only when the effusion is extremely large that the curve of Ellis and Damoiseau can be defined. Small areas of fluid will escape detection and often the diagnosis will be incomplete.

Having arrived at a suspicion of fluid, the diagnosis can only be determined by the aspirating needle. Moreover, it is the only sure method of determining the character of the fluid. In a few cases, aspiration is at once diagnostic and a measure which is conducive to cure. By the withdrawal of a very small amount of the simple effusion, absorption has been promoted. If the fluid is purulent, it should be removed without delay in order to prevent an empyema with last-

Fig. 4.—Showing extraordinary development of sound side fourteen years after expulsion of pus from pleura.

ing damages to the thorax, if not death to the patient.

In casting about for diagnostic means by which to attain the desirable and needful certitude, the radioscope has been faithfully appealed to, but in vain. One reliable aid is ever near at hand—the exploring needle. The ordinary hypodermic needle is never efficient. A large needle is required, but it need not be over one inch and a half in length. One precaution is to have it small enough to enter between the ribs without extending the wound unnecessarily. If the first puncture fails to secure fluid, a second should follow in forty-eight hours. If the general symptoms, or a previous puncture should intimate the probability of purulent fluid or pus, the needle adopted should be appropriately large.

Unfortunately, most cases are permitted to go on until pus is found, and the time required is very brief. The use of the aspirating needle is delayed until the opportunity is reduced to the necessity of accepting the only thing left in treatment—opening the thorax and draining.

The results lead ever more and more toward the worst sequelæ, for in very young subjects, where the walls are yielding, the change is, other things being equal, very much greater than in

the adult. The expulsion of the fluid, retained long enough to become purulent, has its influence upon the pulmonary elasticity, as well as upon the yielding and tender parieties. The lung never again expands completely, and occupies less space than formerly. The chest will be drawn inward, the diaphragm dragged upward, the shoulder of the affected side droops, and, in consequence of paralysis of muscles of the back, the spine yields to the traction of the sound side and we may have a distortion of the spinal column with the convexity toward the active side. The organs lying upon the margins of the unaffected side are thus made to encroach upon the side normally occupied by the lung. The diseased side no longer develops, while the sound side assumes extraordinary dimensions corresponding with its increased functions, and when such a series of misfortunes occur in the very young the deformity becomes more unsightly as the size increases, for the sound side grows with the growth and develops in harmony with the extra functional stress placed upon it.

The behavior of the fluid may betray its character. Absorption is the natural result if the conditions are favorable. However, serous exudate during infancy is not so readily absorbed as in adults. If the fluid lingers, its non-disappearance is probably due to its not being simple serum. Excessive sweating, anemia and hectic, observed in the presence of pus, do not exclude a consideration of the possibility of tubercle. The etiological factor should be sought for in every case, and the treatment made to conform therewith. Tuberculosis is demonstrated by the presence of bacilli in the fluid. Absence of bacteria in the pus constitutes the probability of tuberculosis. Streptococci and staphylococci are present in some cases of tuberculous empyema. Pneumococci ordinarily denote *meta pneumonia.*

Diseases of the heart, kidneys, inflammation of the liver, localized peritonitis, as appendicitis, and also lues, may act as causative agents in pleuritis. Pleurisy is a frequent complication of acute infectious diseases. We must bear in mind that empyema is common in children without more obvious reason than that the pleuritic attack is severe, or the resistance feeble. Empyema in babyhood is often that from the start.

Early evacuation of serous fluid should leave no other evidence than the scar upon the chest. In all cases where there are relapses, or a slow progress toward convalescence, an exploratory puncture should be made to determine if the cause is purulent fluid. The presence of pus constitutes an imperative demand for evacuation, as its presence precludes absorption. Two tubes should be used and safely secured in place covered with antiseptic gauze. These will soon drain the cavity and need not be retained long. Aspiration will not meet the needs and an incision will be the most conservative method, although resection may be required. Tonic treatment, including strychnine, iron, arsenic, etc., and, if possible a change of air and plenty of sunshine, are to be commended. Where needed change is denied, the inhalation of oxygen may become a valuable substitute. The medicinal treatment includes few remedies in the presence of sepsis. Support and stimulation of the circulatory system with caffeine, digitalis, strophanthus, strychnine, etc., are available. Bromides should be used in preference to chloral for restless conditions and codeine and Dover's syrup for pains and cough.

Treatment should include some effort toward prevention of the deformities already pictured. The earlier the child is taught to use deep breathing, the better for the crippled lung. Forceful breathing in positions of advantage to the weakened side may be inculcated as early as the subject is capable of learning. Prior to the voluntary self-exercise, the attendant should lift the arm and shoulders off the thorax and aid in producing respiration. The shoulder should be raised from the thorax during the period of sleep. Postural respiration will be useful during childhood and adolescence. When the child is sufficiently grown, there will be observed an inclination to carry bundles, packages, books, etc., beneath the arm upon the crippled side, as it seems better adapted therefor than the one which is excessively developed. This disposition must be corrected, as it promotes deformity. A habit of resting the hand upon the hip or other means of support and lifting the weight of the shoulder and arm from the weakened side will prevent much of the inequality which otherwise must follow. The clothing should never be suspended from the shoulder of the injured side, and during some portion of each day deep inspiration and forced expiration should be practised with the body inclined toward the sound side while the hand upon the diminished side is grasped well above the head lifting the shoulder from the chest.

Illustrative ot the results of pleurisy with effusion in infancy the following case is instructive.

Infant, J. W., at four months was attacked with what was supposed to be an attack of pneumonia. The physician then in attendance treated during a period of eight weeks. The record is wanting until the patient was treated by Dr. J. A. Duncan of Pittsburg, Pa. At this time an empyema was evident and it was treated by immediate evacuation and a drainage-tube. The time included from first illness up to this treatment was a little less than four months. The drainage was completed and the wound closed after three months. The results, however, upon the elasticity of the tissues of the lungs and thoracic development remained and the photographs presented show fairly well the deformity resulting. The subject is now sixteen years of age and has been under my observation during a period of two years. The treatment as above outlined has been adopted and the deformity continues without increase, but no hope can be entertained of any restoration to a more normal size or function of the parts.

TENDON AND MUSCLE TRANSFERENCE AND ARTHRODESIS IN INFANTILE PARALYSIS.

BY E. H. BRADFORD, M.D.,
OF BOSTON.

ALTHOUGH it has been said that, as the science of healing advances, the two branches of medicine and surgery would become so interwoven as to be practically inseparable, yet it is true that the range of pure surgery, or the handiwork of the art of healing, is increasing day by day. An illustration of this truth can be found in the surgical treatment of the results of anterior poliomyelitis. The two following cases may be cited as illustrative:

Case I.—A boy of six was brought for treatment suffering from the effects of infantile paralysis and showing nearly complete paralysis of the left leg and thigh. There were no contractions; ability to move the toes and slight power of flexing the knee remained. The glutei and a portion of the adductors retained some strength, but the quadratus femoris and the controlling muscles of the foot were paralyzed. The case was one demanding mechanical treatment and an apparatus was furnished with which the boy was able to walk freely without the use of a cane. Without the apparatus locomotion was impossible except with the use of crutches. This condition continued and the boy grew to manhood, gaining complete freedom in locomotion with the use of the apparatus, but being unable to do anything without it.

In this case the treatment consisted simply in the selection and application of a properly-devised apparatus. With this the condition of infirmity is so far ameliorated that the patient has become a self-supporting wage-earner.

In the second case more was accomplished by means of direct surgical intervention.

Case II.—A boy of eight was taken with extensive infantile paralysis, involving the muscles of the trunk and several muscles in both lower extremities. Recovery took place to a limited extent, but the patient was left with a severe lateral curvature and inability to walk without the use of crutches or a cane. There was a valgus position of the left foot and a varus of the right, with a tendency to equinus. There was inability to extend the right leg at the knee, which dropped when weight was thrown upon it. After a period of the usual treatment of electricity and massage, the sartorius muscle was transferred to the tendon of the rectus femoris. In six months the ability to extend the leg had recovered so that no apparatus was needed when weight was thrown upon that limb. The transference of one of the tibial tendons to the perineal attachment prevented the tendency to varus and the boy at the age of fifteen is able to walk freely without mechanical appliances to the right limb, but needing in the left foot a slight ankle support.

Case III.—This case will illustrate the advantage of more radical surgical intervention. A pauper was brought to one of the hospitals with a complete paralysis of the right lower extremity. No continued treatment by apparatus was feasible, and it was decided to stiffen the knee-joint. This was done by cutting down upon the knee and removing the cartilaginous surfaces of the femur and tibia. Firm union took place and a few years later the girl was able to obtain her livelihood as a waitress. She needed no apparatus.

The three methods illustrated by these cases, *viz.*, mechanical treatment, muscle and tendon transference, and the stiffening of the joint, are measures which demand a combination of considerable skill and judgment in the suitable application of each to individual cases. A consideration of the disease is not here presented. As is well known, medication is of little value at the later stage of the affection when the patient is brought to the surgeon in a crippled condition, the problem being the restoration to the patient of as much function of the limb as is possible. This involves the correction of the deformity in some instances which will not be considered here; nor will a description of the various appliances needed for the correction and prevention of deformity be entered upon in this place. This paper is intended to call attention to the value of the application of both tendon and muscle transference and arthrodesis in many of the cases of poliomyelitis.

Although the palsies following anterior poliomyelitis vary greatly, in many instances certain muscles retain some power and this power is capable of development from use and of degeneration in case it is not used.

In the lower extremity, in the severest cases, all the muscles are affected, including the adductor group and the glutei. Such cases appear to be beyond the aid of operative surgery. Arthrodesis, stiffening of the hip, knee- and ankle-joint, suggests itself, but the measure seems to be of questionable value, owing to the clumsy condition in which the limb is left. The application of an apparatus with the aid of a cane appears in cases of this sort to be the only resource.

Where, as is more frequently the case, some muscles remain, an advantage can be gained by the employment of the non-paralyzed muscles. The muscles frequently left retaining some power are the sartorius, the adductor group and the hamstrings. The transference of the sartorius to the rectus is a measure which can be done without difficulty. The obstacle met is usually the abnormal position of the sartorius, which is often nearer the hamstring at its lower attachment. A curved incision at the lower end of the femoral will bring to light the attachment of this muscle, which should be entirely freed, brought up and transplanted into the firm sheath of the extensor cruris. Where the sartorius is found to be weak the outer hamstring or adductor can be detached and brought forward and inserted on the outer side into the fascia and tendon of the extensor cruris. Where the adductor group is completely paralyzed the problem presented is certainly a

difficult one. Whether the transference of the glutei can in any way be accomplished to supplement weakened adductors is uncertain, but this is perhaps within the limits of possibility as is also the shortening of the paralyzed adductors that they may act as a cord to check extreme abduction. In paralytic disabilities of the knee where all the muscles are paralyzed, making muscle transference impossible, arthrodesis is a method only to be resorted to in cases where no mechanical treatment is possible. That a useful limb can be furnished in this way has been abundantly shown, but the resulting stiff knee can be avoided by a properly-constructed apparatus, usually preferable to the annoyance of a stiff knee.

In the paralysis of the muscles controlling the action of the feet, the combined employment of arthrodesis and tendon transference is of great value. These paralyses may be grouped as follows: (1) Palsies of all the muscles controlling the movements of the feet; (2) palsies of the anterior group; (3) palsies of the anterior group, except the extensor proprius pollicis; (4) palsies of the perineal group alone.

Where the muscles are all paralyzed in the front of the foot, the tendo Achillis can be split and a portion transferred and attached to the paralyzed peroneus tertius or to the tibialis anticus, or both. The procedure is not difficult and is performed by making an oblique incision on the outer side of the leg, securing the tendon of the tibialis anticus and of the peroneus tertius above the anterior annular ligament, following them well up to the muscular origin in the leg. A portion of the tendo Achillis is cut off and passed obliquely forward and stitched to both of the cut tendons.

Where the gastrocnemius is paralyzed, several procedures have been recommended. The insertion of the tibialis posticus and one of the peronei; the splicing of the tendo Achillis, all are used. The latter, the shortening of the tendo Achillis, has not proved of as great value as the insertion of the tibialis posticus or the peroneus brevis.

The success in these undertakings depends, not only upon the amount of care in the performance, but also upon the uncertain quality of the strength of the muscles, which is something which is not to be readily determined before an operation.

In considering the treatment of these paralyses it is necessary to bear in mind the peculiar anatomical condition of the joints of the foot. It will be remembered that in addition to the ankle-joint proper with an up and down movement, *i. e.*, the tibio-astragaloid joint, there is the mid-tarsal or Chopart joint, or the articulation between the astragalus and the scaphoid, the os calcis and the cuboid, giving a side motion with a certain amount of obliquity. In addition to this a certain amount of play will be found in the metatarso articulation, particularly in the first metatarsal.

Tendon transference is of value for the purpose of preventing the dropping of the front of the foot, or where the anterior group of muscles have been weakened. Where either the extensor proprius pollicis, anterior tibial, or the peroneus tertius are unparalyzed, they can be transferred to either side and in that way give power for the raising of the front of the foot. Whether this can be done successfully will depend upon the strength of the muscle and the length of the foot. If any of the muscles of the toes remain unparalyzed it is possible to utilize the extensor communis digitorum by uniting a paralyzed anterior tibial or peroneal muscle or muscular fascia to the extensor communis digitorum. In this way in many cases the dropping of the front of the foot can be prevented.

In many of the older cases of this affection, distortion develops from the adapted shortening of the soft tissue. Valgus and varus deformities are established, induced at first by the inequality of the strength of the muscles and aggravated by the abnormal strain brought upon the various portions of the bones. Under these conditions simple tendon transference is not sufficient to prevent a relapse after a correction, as the transferred tendons are not sufficiently strong to withstand the unusual strain brought upon the foot. Under these circumstances arthrodesis of the mid-tarsal articulation is of a special service. No difficulty is met with in this operation. An external incision is made and the articulation between the os calcis and the cuboid laid bare, the peroneal tendons being pulled aside. The cartilaginous surfaces of the os calcis and the cuboid are removed with a chisel, and if any abnormality in the shape of the bone has taken place this can be removed, as the incision can be enlarged or another incision can be made on the inner side, and the scaphoid and astragalus ankylosed in the same way. This, with proper correction, does not interfere with the up-and-down motion of the foot, but does interfere with the twist which it is desirable to prevent. In cases without muscular strength of any of the muscles of the leg, front or back, an ankylosis between the tibia and the astragalus can be performed, but the advantage of this over a proper appliance is not manifest and the operation hardly recommends itself for this reason. A partial operation to strengthen the ligaments on either side of the ankle by shortening relaxed ligaments is of advantage.

The percentage of complete success from these different procedures in a large number of cases is yet to be accurately determined by further clinical investigation. Where these measures have been carried out, benefit is evident in suitable cases and it is desirable to call attention to the advantage of a combination of arthrodesis and tendon transference, *i. e.*, to the employment of one or both with or without suitable apparatus in proper cases, and to emphasize the fact that the surgeon has, in the management of this disability difficult of treatment, an opportunity for the employment of surgical judgment, anatomical and physiological knowledge, and the exercise of trained skill with the expectation that in a large percentage of cases benefit will follow his properly-directed efforts.

THE MANAGEMENT OF ACUTE GONORRHEA.

BY LOUIS BROTER, M.D.,
OF NEW YORK;
FORMER ASSISTANT, GENITO-URINARY DEPARTMENT, GOOD SAMARITAN DISPENSARY.

Among all diseases known to medical men there are few, if any, for which so many remedies have been advocated and used as in gonorrhea. It would be more than useless for me to describe them here, for in this brief article space is only given for the latest and best methods of treating this disease as derived from the experience of well-known men on this subject and my own experience as well.

When a patient comes to a physician's office with a discharge from his urethra, the physician should not express an opinion that it is gonorrhea unless microscopical examination is made and gonococci are found, for if it is a non-infectious urethritis the duration, course and prognosis will vary widely from that of a true gonorrhea. The treatment of a non-infectious urethritis will also differ decidedly from that of infectious urethritis. As a rule, the only treatment necessary in non-infectious urethritis is removal of the cause; rest and an alkali to ensure a bland condition of urine. After the discharge is examined and gonococci are found, treatment should be instituted in the following way:

Abortive Treatment.—Many abortive methods are advertised in public newspapers by quacks, some of whom specify the duration of the disease as being from five to eight days, but such rapid cures place the life of the innocent patient in jeopardy. I regret the condition of a patient who falls into the hands of these quacks. The physician must remember that checking a discharge does not necessarily mean curing gonorrhea. For a number of years experiments were made with various drugs such as silver nitrate, bichloride of mercury, etc., with the idea of immediately killing the gonococci, but it has been all in vain. They have only succeeded in producing lesions of various kinds in the urethra, setting up all kinds of complications, thus prolonging the duration of the disease. Those cases which were reported as aborted were either non-infectious or pronounced cured when the discharge had ceased. It is now known to every intelligent practitioner that the discharge may disappear and return after an elapse of a few weeks, for the gonococci penetrate the surface of the mucous membrane of the urethra and remain lodged in the deeper tissues, hence attempts to kill the gonococci immediately would mean to completely destroy the mucous membrane. This is manifestly an absurd procedure. Let us, therefore, be convinced that at present no remedy is known which will abort a true gonorrhea and let us hope that in the future we will have a remedy which will not only abort but prevent the occurrence of this disease.

Local Treatment.—Of all methods known I find the irrigation method the best. In 1894 not a dozen men in the world were using the irrigation treatment in gonorrhea. Many had attempted and discarded it; owing to defective apparatus and ignorance of technic, unfortunate results were obtained. Among the earliest successful men were Felicke of Budapest, Jenet of Paris, E. R. W. Frank of Berlin and Swinburne of New York. Afterward this method of treatment became known as the "Valentine method" and still preserves its name. To Valentine belongs the credit of devising a simple apparatus, developing the technic, rendering rules precise and of writing a number of articles pointing out the advantages and disadvantages of this method. The irrigator is too familiar to the profession to be described.

Method of Irrigation.—The method of irrigation is worthy of description, for, although thousands of physicians are using this method, many are using it in different ways. After urinary and microscopical examinations are made the patient is instructed to drop his trousers to his knees, to roll up the shirt and undershirt, thus exposing the abdomen. A rubber apron having a hole in the middle for the penis, thus avoiding soiling of clothes, is then put on and the patient stands close to a stand having a basin in the center which I use for this especial purpose. The patient's eyes should be directed to the percolator of the irrigator to thus engage his attention. This is especially good for neurotic patients.

The stand is placed to the left of the irrigator. The percolator is raised as high as three feet. Have a standard solution of potassium permanganate, 1-4000 in 1 quart of water, in the percolator. This may be increased up to 1-1000 as the disease advances. The temperature should be at least 100° F. and may be increased up to 112-120° F. as the patient becomes accustomed to it. The physician stands near the irrigator and to the right of patient. Several clean glasses should be placed on a stand for testing urine; one glass should contain a solution of oxalic acid to remove stains caused by permanganate; one glass of strong lysol solution or strong bichloride to keep the nozzles in, so as to prevent re-infection. Before each irrigation the nozzle should be washed with boiling water. After use, place it in lysol or bichloride. At night wash same with hot soda solution. Unless the above precautions were taken the nozzles should not be used, for it would be criminal negligence to produce re-infection.

Take the penis in the left hand between index, middle and thumb fingers; take the stopcock of the irrigator in the right hand; hold the nozzle under boiling water to wash away all microorganisms and dirt. Allow some of the solution to flow on glans, foreskin and meatus. Now direct the stream into the urethra with gradual increase. Should it be desired to wash out the posterior urethra or the bladder, the nozzle must be brought in close proximity to the meatus, at the same time telling the patient to attempt to urinate. This last act, as will be readily under-

stood, loosens the cut-off muscle and the solution gains an entrance. This is continued until an entire quart of the solution is used. After irrigation I inject into the urethra three drams of a 2-per-cent. solution of protargol through an ordinary urethral syringe. The patient is instructed to keep the meatus closed by pinching it with his fingers and he thus retains the solution for from 5 to 10 minutes, after which he allows it to flow out. Some patients will faint during this act. I would, therefore, suggest that they be placed in the recumbent posture, especially the first time. The number of irrigations will vary with each individual case. I usually make it a rule to give irrigations of permanganate twice daily, followed by protargol, until the discharge has lessened and it has changed from a purulent to a serous character. This usually takes from two to three weeks. After this I give irrigations once daily, followed by injections of zinc or lead or both; sometimes I add bismuth to the above two drugs. I find that zinc and lead have a great tendency to check the slight discharge which is seen in the declining stages of the disease. After the urine is clear and the discharge and gonococci have disappeared, I still give irritations once a week for another month.

I have found that since I began the irrigation method chordee has been absent, no complications have arisen and the duration has been shortened. It is impossible with a 3-dram syringe to do away with all the mucus, pus and gonococci which become impacted within the urethra during the intervals of treatment. On the other hand, with the irrigation method we are enabled to give the urethra a thorough mechanical cleansing, flushing it out, at the same time killing the gonococci because of the germicidal effect of the potassium permanganate. I believe that any physician who has any experience at all with the irrigation treatment will agree with me that this method is one of the greatest blessings that human thought and observation have furnished to mankind.

Constitutional Treatment.—Alkalies and diuretics are best employed to keep the urine unirritating. Bicarbonate of soda in one-dram doses twice daily may be used. Potassium acetate in 5 to 20-grain doses, t.i.d., is good. A good pill is methylene blue, grain one; boracic acid, grains 5; one t.i.d. A rather serious objection to this is the discoloration of urine and feces. This last pill serves a two-fold purpose. It is a diuretic and urinary antiseptic. It should be given only during the first two weeks. After this time I give oleum santali, balsam copaibæ or the various preparations of cubeb, in capsule form.

There is little room for doubt that hygienic environment is of greatest importance. The patient should rest in bed most of his time in order to lessen congestion of the parts. All exercises, such as dancing, bicycling, horseback and running, should be avoided. Avoid sexual excitement entirely. Daily movement of the bowels is important. No beverages of any kinds such as beer, whiskey, ginger ale, etc., should be used, for they are genito-urinary irritants. The patient should avoid fats, meats, acids or sweets, or any food difficult of digestion. Smoking is to be avoided. Hot milk is very good. It is the duty of the physician to impress upon the patient that, unless he will carry out all his orders, complications will invariably occur. It is also the duty of the physician to get out all superstitions and fictions which some of them have learned from their friends, such as: (1) "Drinking away a clap," *i.e.*, drinking all kinds of beverages, thus causing disease to disappear. (2) "Giving away a clap," *i.e.*, having sexual intercourse during disease, thus leaving it with the woman. (3) "Purifying the system," *i.e.*, allowing the discharge to run for at least one or two weeks, thus purifying system.

Unfortunately, these patients come under physicians' observations after they have undergone all above mentioned experiments.

273 East Broadway.

MEDICAL PROGRESS.

Orthostatic Albuminuria and Scarlatinal Nephritis.—Functional albuminuria is now divided by most writers into two main groups, the cyclic, occurring at a certain hour of the day, independently of fatigue and of digestion, and the orthostatic, determined by the upright posture. Orthostatic albuminuria, according to C. AUBERTIN (*La Presse Méd.*, Oct. 9, 1901), is really not purely functional, but is commonly a relic of infectious nephritis and occurs where there remains a certain degree of renal insufficiency. Aubertin describes a case of scarlatinal nephritis in which, after the initial period of continuous and abundant albuminuria, there followed six or seven weeks of albuminuria of posture, not influenced in any way by fatigue, alimentation or electricity. Albuminuria was still present ten months after the scarlatinal attack, but was gradually influenced less and less by mere posture, while diet, muscular exercise, etc., became more and more important as affecting the renal function. Among the previously published cases of orthostatic albuminuria the majority give a previous history of some infectious disease, probably involving the kidney and rendering it susceptible to disturbances of function.

Gangrenous Erysipelas and Streptococcus Serumtherapy.—Antistreptococcus serum from the laboratory at Bern was used with apparent success in a case of gangrenous erysipelas by A. Joss (*Corresp.-Blatt f. Schweizer Arzte*, Oct. 1, 1901). The patient was a woman who, during the last few days of pregnancy, suffered from a severe nasal catarrh; the day after her child was born she experienced pain and a sense of tension in the nasal region, and a day later severe erysipelas covered the right side of the face. Sodium salicylate and antipyrin were

given internally and the skin over the affected area was painted with carbol-turpentine-glycerin. Two days later gangrene appeared in the skin covering the eyelid, the swelling advanced into the scalp and the labia majora became red and swollen. Extension of the gangrene and the appearance of bed-sores with increased infiltration about the labia were the next developments; the patient began to look "typhoid"; her pulse was 130, respirations 40, temperature 38.5° C. Six serum injections were made, the first 20 c.c., the remainder 10 c.c. each. The pulse became less rapid after the second injection and continued to improve while the treatment was continued. Necrotic tissue came away from the eyelid and labia majora. The patient later showed physical signs of a disseminated bronchopneumonia (probably streptococcus pneumonia) with bloody sputum. The temperature fell rapidly as soon as the gangrenous masses were cast off. In view of the severity of the infection the writer believes that but for the serumtherapy the case would have terminated fatally.

Causes and Treatment of Vomiting in Pregnancy.—Persistent vomiting during pregnancy is not a morbid entity, but a mere exaggeration of the milder form which occurs so frequently. Three theories of causation are given, namely: (1) Nervous disorder; (2) reflex originating in the genital organs; (3) intoxication. While the nervous theories cannot be wholly set aside, M. HUGE (*La Presse Méd.*, Oct. 9, 1901) considers most cases of incorrigible vomiting to be due to intoxication. The cause is to be sought in disorders of the liver, kidneys, stomach or intestines, superinduced by the excessive work imposed on these organs by pregnancy. Treatment may address itself to the nervous state of the patient, to the gastric condition, and to the systemic intoxication. Reflex nausea due to uterine lesions or displacements calls for treatment of these conditions. By careful dieting and appropriate medication gastric digestion must be promoted and cardiac erethism controlled. The urine always demands close study; albuminuria or diminished urea suggests a milk regimen; antisepsis of the alimentary tract is an important indication. Rectal alimentation may obviate in part errors of digestion and absorption incident to feeding by mouth. Evacuation of the uterus is a last resort.

Glycosuria and Life Insurance.—The rigorous and unqualified rejection by life insurance companies of all applicants suffering from glycosuria is held by A. SIREDEY (*La Méd. Moderne*, Oct. 2, 1901) to be an unnecessary and unjustifiable practice. He believes that the interest of the companies does not demand the rejection of diabetics over thirty-five years of age who are well nourished and whose organs are apparently sound, although prudence might dictate in these cases a slight advance over ordinary premiums. Where glycosuria follows overwork, emotion or traumatism a re-examination after six months will often reveal a radical change for the better; hence in this class of cases postponement and not rejection is indicated. Siredey, however, endorses the existing rule of rejection so far as it applies to individuals under thirty-five years of age and to cases of emaciating diabetes at all ages.

Extraserous Transposition of the Testicle.—A method of extraserous transposition of the testicle was proposed by L. LONGUET in October, 1900. With certain modifications in technic this method is again recommended by the same writer for the treatment of hydrocele of the tunica, testicular ectopia and cysts of the cord. Longuet gives the results of 56 operations (*Le Progrès Méd.*, Sept. 21, 1901), 50 of which were done either for hydrocele or hematocele. He utterly renounces "combined eversion and excision" of the tunica vaginalis in enormous hydrocele; experience teaches that simple transposition of the testicle suffices, however large the vaginal cyst. The removal of the fluid-contents of these cysts is followed by a prompt disappearance of the enormous pocket, the walls shrinking in virtue of their elasticity. Among Longuet's first series of cases of hydrocele and hematocele, published in 1900, post-operative history has been obtained in eight instances, and in none of these has there been any return of the original condition. Nothing was gained, however, in three cases of testicular ectopia with shortness of the cord; better results may be anticipated where the cord is of sufficient length. Longuet's method has been applied to the treatment of varicocele too recently for the obtainment of evidence as to its remote effects; but in three reported cases the operation was followed within five days by cessation of pain and disappearance of the varicose tumor. The ordinary procedure is high transposition of the testicle in varicocele, low transposition in ectopia, internal transposition in hydrocele. Transseptal displacement is an exceptional resort.

Diphtheria.—Notwithstanding all that has been accomplished with respect to this disease, both from therapeutic and diagnostic standpoints as the result of scientific research, there still remains much that is obscure in regard to the exact bacteriological conditions which underlie its various manifestations. The precise relations between true and pseudodiphtheritic bacilli have not as yet been fully ascertained. The study by LOUIS CORBETT (*Jour. Hygiene*, Oct. 1, 1901) of the epidemic which occurred in Cambridge, England, in the spring of 1901, is of interest from several standpoints. As the result of his work he holds that there is no reason for believing that the pseudodiphtheritic bacillus is other than perfectly innocuous to man. It is an error to believe that true diphtheria bacilli are distributed among the healthy members of a community free from diphtheria. He found genuine diphtheria bacilli in the healthy throats only of those who had come into more or less direct contact with actual cases of diphtheria. Partially attenuated bacilli were never found and in no case investigated was a virulent bacillus replaced by a non-virulent before its disappearance. Whether persons without

apparent illness who are found to have true diphtheria bacilli in their throats should be reported as cases of diphtheria is a mooted question. The difficulties which stand in the way of such a procedure are manifold. Nevertheless the institution of such a measure would be of undoubted benefit in controlling the spread of the disease.

Etiology of Vaccinia.—Although a large amount of work has been done upon this subject it is not as yet absolutely decided whether the causative agent is of a protozoic or bacterial nature. Dr. von Wasielewski (*Z'tschrift f. Hygiene u. Inf.*, Oct. 4, 1901) has contributed extensive investigations along this line. His work comprises both microscopical study and experimental research. He arrives at the following conclusions: (1) The vaccine bodies are peculiar, characteristic forms which are present in variola and vaccinia but absent in other conditions and in health; the bacteria described as producing vaccinia are saprophytes and devoid of etiological significance, as the action of bacteria-free lymph proves. (2) These bodies appear in the cuticle epithelial cells of rabbits without fail shortly after the virus is introduced. (3) They cannot be made to so appear by the employment of any substance save vaccine virus. (4) These bodies are neither leucocytes nor products therefrom. (5) That they are derived from the nuclei of the epithelial cells is contradicted by their appearance in absolutely normal cells, their presence in mitotic dividing cells and their usual position in the periphery of the cell removed from the nucleus. (6) That they arise from the cell protoplasm as the result of the action of a specific poison is improbable. (7) The size, form and configuration of these bodies, as well as the method of their multiplication and the appearance of degeneration forms, tend toward the opinion that they are "parasite cells" (protozoa). (8) The changes brought about by their presence in the epithelial cells supports this view. (9) Since no regularly appearing bacteria are uniformly present in the inoculated area, these bodies must be regarded as the etiological factors in the causation of vaccinia.

Antipyretics in Acute Infectious Conditions.—Ideas concerning the mode of production and significance of fever in acute infectious conditions have during the last few years undergone considerable alteration from those formerly held. Discoveries which have shown the presence in these conditions in the blood of various substances giving rise to the bactericidal and agglutinating sera have led to the opinion that the fever at least in part is the result of the reaction occurring in certain cells and organs where these substances are produced. As the production of these substances largely determines the clinical course of any given infection, it becomes of interest to ascertain whether the employment of antipyretic agents has any influence upon the production of such bactericidal or agglutinating substances. Albert Schültze (*Z'tschrift f. Hygiene u. Inf.*, Oct. 4, 1901) attempts to solve this question by the means of experimental research. His investigations were limited to the study of antipyrin. He inoculated rabbits intravenously with typhoid cultures. These in a few hours developed a rise of temperature. Into some he then introduced hypodermically small quantities of antipyrin, while others were maintained as controls. Those receiving the antipyrin showed a marked and prompt fall of temperature. No differences in the bactericidal or agglutinating power of the blood was observed between the animals so treated and the controls which received no antipyretic medication. This shows that antipyrin exerts no unfavorable influence over the formation of specific immunizing substances.

Pathology of Aneurism.—Some diversity of opinion is prevalent with respect to the pathological changes which underlie the formation of aneurism. The earlier conception was that simple inflammatory processes of the tunica intima and media were the chief causative factors. Latterly traumatism has been regarded as plying the most important part in the origin of this condition. A. Fabris (*Virchow's Archiv*, B. 165, H. 3) has investigated this subject by the means of experimental research. He observed the effect of traumatism upon the arteries and the intensity and duration of the changes thus produced. These he compared with the alterations occasioned by other lesions which give rise to aneurism. The result of his work shows that traumatism produces in the arterial wall rents of various size followed by degeneration of the elastic fibers. There occurs only a slight increase of the lumen of the vessel, which soon disappears in consequence of the regeneration process. In addition to the formation of new elasic fibers there occurs also an hypertrophy of the muscular coat of the vessel. The tissue thus regenerated, being of less functional value than the original structure of the vessel, undergoes dilatation which persists and gives rise to the formation of aneurism.

Treatment of Carcinoma.—A new method of combating this group of malignant tumors is suggested by F. Loeffler (*Deut. med. Woch.*, Oct. 17, 1901). He proposes the inoculation of persons afflicted with carcinoma, especially the inoperable cases, with the plasmodium of tertian malarial fever, and bases his proposition on the following facts. Various observers have noted that carcinomatous growths have been inhibited and that improvement has taken place when the patient in question became subjects of a malarial invasion, and, moreover, that in the tropics, where malarial diseases abound, carcinoma is practically unknown. He also believes that carcinoma is on the increase in Central Europe, since malaria has been successfully combated and the number of its sufferers reduced. Further and more detailed observations are necessary in what may prove a great field for future discovery and investigation.

Infectious Parotitis.—A case in a young

adult with severe symptoms resembling typhoid, is reported by E. Schwartzkopf (*Deut. med. Woch.*, Oct. 17, 1901). The invasion was marked by chill and rise of temperature, with headache, vertigo, abdominal pains. Alternate states of stupor and delirium followed. Region of liver and spleen very tender to the touch, abdominal wall tense. Testicles not involved. The differential diagnosis from typhoid depended on the enlargement of the parotids, the presence of an epidemic of mumps in that locality, the absence of the characteristic eruption, and the rapid recovery.

Dysenteric Bacilli.—Since the bacteriological investigations by Shiga of epidemic Japanese dysentery much work has been done with respect to this subject by various observers in many different countries with the result that several organisms have been isolated and proclaimed as the causative agents in different dysenteric epidemics. Simon Flexner (*C'tlblt. f. Bak.*, Oct. 12, 1901) has undertaken the comparative study of several of these so-called dysenteric bacilli. The organisms thus compared were Shiga's, Kruse's, Flexner's, and in addition several received from Manila and Porto Rico. A comparison of their morphology shows only minor variations which are confined to differences of length and breadth. All possess motility and flagella, although this observer was unable to demonstrate the presence of the latter. The agglutination reaction is of the greatest importance. The blood used for this purpose was obtained from Manila and Porto Rico, also from several cases of dysentery in the Philadelphia Hospital and in Morven, N. C. The serum of partially-immunized goats was also employed. All of the bacilli examined were agglutinated by every one of the bloods mentioned. The reactions, however, were not always of the same intensity, in some cases to produce a given reaction weaker dilutions being required than in others. The inter-agglutinatability of these organisms leaves little doubt as to their common identity and indicates that the dysenteries occurring in the Far East, Germany, West Indies and this country, are caused by the same organism, and justifies the view that the determination of a specific organism of dysentery is near at hand.

Physiological Action of Suprarenal Extract.—More exact physiological research on this substance or substances is given by J. N. Langley (*Jour. of Phys.*, Oct. 16, 1901). He observed the effect produced when introduced subcutaneously or intravenously into cats and rabbits. Certain varieties of commercial suprarenal tablets were used as was also the extract prepared directly from the gland. No wide variation was observed in the action of products obtained from different sources. In obtaining the extract from the gland this was removed from the body directly after death and dried in a desiccator. When about to be used the dried substance was first ground with sand and then with a .75-per-cent. salt solution, a drop of acetic acid being added. The mixture was then boiled and filtered. The proportion of dried gland to salt solution was 1 to 100. He finds that the inoculation of this substance gives rise to an increased secretion of all the salivary glands as well as from the buccal, esophageal and tracheal mucous membranes. It causes a primary pallor of these tissues followed by a flushing. There occurs an increased, followed by a decreased flow of bile. It does not produce a secretion from the pancreas, but may increase a secretion already existing. No secretion from the sweat-glands is produced. It causes an inhibition of the urinary bladder, intestine, gall-bladder, cardiac sphincter of the stomach and the stomach itself. It produces dilatation of the pupil, protrusion of the eyeball and retraction of the nictitating membranes. It causes contraction and pallor of the uterus, vas deferens and seminal vesicles. Its action upon the arteries is unequal, producing a more marked contraction of the medium-sized arteries of the abdominal viscera than of the smaller, but easily visible ones. It always causes great contraction of the very small vessels, either arterioles or capillaries. There occurs a marked rise in blood-pressure. It causes a paralysis of the vagus which is, however, of brief duration.

Hemolytic Action of Typhoid Bacillus.—The ability of various micro-organisms to give rise to metabolic products which cause the disintergration of the red blood-cells has recently been extensively investigated. It has been found that, as a rule, pathogenic bacteria possess this property which is exercised, however, within wide limits, varying markedly with the various species of microbes and the external conditions under which they find themselves placed. E. Levy and Prosper Levy (*C'tlblt. f. Bak.*, Sept. 30, 1901) show that the typhoid bacillus possesses marked hemolytic power. In their work they employed filtrates of 14-day cultures of this organism in weakly alkaline bouillon. A very small amount of such filtrate when added to dog's blood caused rapid and complete disintegration of the red cells. Dogs which were inoculated subcutaneously with sterilized typhoid cultures showed, after six days, the presence of anti-hemolytic substances in their blood-serum. When a small amount of such serum was added to normal dog's blood the disintegration of the red blood-cells by the products of the typhoid bacillus was entirely prevented. These anti-hemolytic substances may be submitted to a temperature of 56° C. without undergoing alteration.

Cholecystitis and the Bacillus Typhosus.—Although in many cases of cholecystitis, accompanying typhoid fever, typhoid bacilli have been isolated from the gall-bladder, most of the cases so reported are open to the objection that the organisms so obtained have not been fully identified, the agglutination test not having been employed. Albert Brion (*C'tlblt. f. Bak.*, Sept. 30, 1901) reports a case of cholecystitis occurring in typhoid fever. The contents of the gall-

bladder were examined twenty-seven hours after death and showed a pure culture of the bacillus typhosus. These organisms when inoculated into a rabbit gave rise to a serum which agglutinated known typhoid bacilli in a 1-300 dilution. There remains, therefore, no doubt of the identity of the organisms isolated.

Metachromatic Granules in Spore-forming Bacteria.—Numerous observers have demonstrated the presence of various varieties of granule formation in the protoplasmic bodies of certain spore-forming bacilli. Recently E. KROMPECHER (*C'tlblt. f. Bak.*, Oct. 8, 1901) has shown the presence of metachromatic granules in the bodies of several such species (b. anthracis, b. concentricum and b. anthracoides) when they have been submitted to artificial cultivation upon agar, potato or gelatin. This form of granulation has not been hitherto described and its mode of development is unknown. When stained with carbol-methylen blue, they take a bright red color even when the organism has been exposed to an extremely elevated temperature. They usually appear in the center of the bacillus. It is thought that they are concerned in spore-formation, since they only occur in spore-bearing organisms and are resistant to heat. They are easily differentiated from the Babes-Erust bodies by their location in the bacillus and their metachromatic staining properties; moreover, both of these varieties of granulation may be present in the same organism. In general it may be said that no relation exists between the number of Babes-Ernst bodies present and the virulence of the bacillus.

Anemia with Chronic Enlargement of Spleen.—After studying the literature of anemia splenica infantiva and anemia infantum pseudoleucemica, A. H. WENTWORTH (*Boston Med. and Surg. Jour.*, Oct. 31, 1901) concludes that these are identical conditions and that the apparent differences are due to the fact that the observations were made at different periods. Before 1890 modern methods of blood-examination were not generally employed; after 1890, when most of the work on anemia infantum pseudoleucemica was done, blood-examinations absorbed everybody's attention to such an extent that observation of the clinical course of the disease was neglected. The blood-changes in so-called splenic anemia are those of a secondary anemia; the degree of anemia varies in different cases. The degree of cachexia may not correspond with the blood-changes, which are often moderate. The cachexia is probably due to a chronic intoxication similar to that produced by cancer or tuberculosis. The mere interference with splenic function from overgrowth of fibrous tissue could not produce the symptoms described as characteristic in these cases; it is known that the splenic functions, whatever they may be, are not essential to life and probably not essential to the health of the individual. While fibrous changes can cause interference with the functions of an organ, it is not easy to see how they can produce toxin. Besides, chronic fibrous changes in the spleen are associated with a variety of well-known causes, and toxic substances are not present in many of these conditions. The statement that splenic alterations are primary lacks confirmation. Bruhl believes that the splenic enlargement may follow or precede the anemia. Nothing really characteristic of a primary disease has been discovered in any organ or in the blood in reported cases of splenic anemia. There is no apparent connection between the character of the blood and the splenic changes in infancy; there are varying degrees of anemia and of leucocytosis in cases with identical lesions in the spleen. These differences cannot be explained by the duration of the disease.

Respiratory Conditions Dependent upon Gout and Obesity.—The deposit of abnormal masses of fat in the abdominal and thoracic cavities encroaches on the breathing space and diminishes respiratory capacity. The weight of external fat deposits restrains respiratory movements and depositions in the upper part of the abdominal cavity prevent full diaphragmatic excursions, These interferences with lung expansion naturally excite dyspnea upon muscular exercise or upon overdistention of the stomach. Dyspnea is more marked in the anemic than in the plethoric variety of obesity. J. M. ANDERS (*Phila. Med. Jour.*, Oct. 26, 1901) calls attention to a thoracic symptom belonging to overfatness, namely, pain in the subscapular and intrascapular muscles; clinically this must be distinguished from rheumatic and neuralgic pains. Hyperemic (passive) bronchitis with coughs and copious mucoid expectoration may be due to restrictions of the thoracic movement and to the enfeebled heart action so often present in these cases. Closely connected with this variety of bronchitis and to some extent dependent on it, is asthma. There is also an asthma in obesity due to gastrectasis associated with a high position of the diaphragm. Cases of asthma due to obesity can be cured by attention to the underlying causative liver condition and a rearrangement of the diet so as to overcome the obesity. Gout often plays a prominent part in asthma occurring in obese subjects, and gout occurring independently may also cause asthma. The dry chronic bronchitis of Laennec is recognized as a distinct variety of bronchitis due to the gouty state. The cough is dry, irritative and attended with slight expectoration. Cardiac, renal and articular symptoms of gout may be absent, but there is a high degree of acidity of the urine, a diminished renal output, large coated tongue and hepatic enlargement. The prime requisite to successful treatment is to recognize the cause of the disease and thus make the lithemic state the object of attack.

Gall-Stones.—The great frequency with which gall-stones are not diagnosed *intra vitam* is commented upon by H. FIEDLER (*Münch.*

med. Woch., Oct. 22, 1901). Of 93,000 patients examined, stones were noted in only 133, making 0.14 per cent., while on the other hand at autopsies fully 10 per cent. of the bodies are found to possess them if a careful examination of the biliary system is made. The Roentgen rays may be looked upon as a valuable diagnostic aid in the future, and already a number of excellent photograms have been published. Best results will always be obtained with the strongly calcareous stones, while the rarer ones consisting chiefly of cholestrin or bile-pigment can hardly be expected to throw a shadow. Concerning the origin of gall-stones, most authors are agreed that disease of the mucous membrane of the gall-bladder is the primary lesion and that the myelen and cholestrin liberated from the fattily degenerated epithelial cells form the nucleus around which successive layers will be deposited. The catarrh may be induced by the colon bacillus, which is often found in the bile when its outflow is impeded. The statement that gall-stones frequently follow typhoid the author cannot agree to, since he has found them only in two cases which came to autopsy and never had occasion to treat those that survived for attacks of colic. With reference to the real cause of the severe pains induced by the larger stones in their passage through the ducts, it is questionable whether an inflammation always exists and it is probable that obstruction alone is responsible for those sudden, severe attacks which rapidly yield to morphine and local application of heat. A complete relief from symptoms must never be expected when a stone has been discovered in the feces, since others are generally left behind which will make trouble unless a closure of the cystic duct or atrophy of the gall-bladder has occurred. Other points emphasized are the frequent absence of jaundice with cholelithiasis, the recurrence after operations, which amount to about 15 per cent., and the intimate relation of carcinoma of the gall-bladder and gall-ducts to stones. Concerning treatment the radical surgical methods are not always in place, though much harm has been done by delay.

Ethyl Bromide in Operations upon Adenoids.—In a discussion upon the desirability of a general anesthetic, and the kind to be used, in operations upon children for adenoid vegetations and enlarged tonsils, J. W. Gleitsmann (*Med. Rec.*, Nov. 2, 1901) recommends the almost invariable employment of some general anesthetic and especially ethyl bromide on account of its safety, its rapid action and few after-effects. It is much superior to either chloroform or the A. C. E. mixture. Ten grams are usually poured into an impermeable mask and after the first few whiffs the entrance of air is practically entirely excluded. Within two minutes the patient is fuly anesthetized and generally less than thirty grams are necessary to complete the operation. For operation the child is held in an upright position by assistants, the pharyngeal adenoids are removed first by forceps and then scraped with a Gottstein curette. The tonsillotomy may be done either before or after the removal of adenoids, but between operations the child's head should be lowered and the blood allowed to flow out. While operating there is usually a reflex spasm of the pharyngeal muscles and respirations are temporarily suspended. It is surprising how seldom any blood enters the larynx.

THERAPEUTIC HINTS.

Chronic Hydrocephalus.—In two cases of this affection Wm. Ewart and W. L. Dickinson (*Pediatrics*, Oct. 15, 1901) obtained complete evacuation of the ventricular fluid by tapping and allowing aseptic air to enter as the fluid was withdrawn. To accomplish this, in addition to the exit cannula and drain, a second cannula was provided with a sterile rubber tube the free end of which was connected with the tube of a small glass syringe plugged with cotton after the piston had been removed. This second cannula was inserted somewhat above the other, and too great rapidity of outflow was guarded against. In the first case eight tappings were carried out, the largest amount of fluid collected being fifty ounces. Each time there was considerable reduction in the size of the head and cessation of the pressure symptoms. There was sometimes a slight post-operative rise in temperature. The hydrocephalic cry gave place to a "baby-wail." The case is still under observation. In the second case there was no re-accumulation of fluid after the first tapping, though oozing continued for several days.

Surgery in Exophthalmic Goiter.—In an exhaustive review of operations for this condition, I. Balacescu (*Revista de Chirurgie*, Apr. to Sept., 1901) sums up in favor of total bilateral resection of the sympathetic nerve, including the three cervical ganglia. Of 19 cases so treated, 10 were cured, 5 much improved, 2 were failures, one died under the anesthetic, and one from an intercurrent disease. Simple section of the sympathetic as practised by Jaboulay in 8 cases, resulted in 2 cures, 5 improved, 1 death. Twenty-seven cases of partial resection of the nerve gave 9 cured, 11 improved, 2 failures, 5 died. A single case of stretching the nerve by Jaboulay was followed by slight improvement. Comparing the results of total resection of both sympathetics with partial thyroidectomy, the author finds that with the latter operation sudden deaths are numerous, failures more frequent, and the relief from exophthalmos, tachycardia, and nervousness not nearly so marked.

Pendulous Abdomen.—In the case of a loose, flabby, overhanging abdomen for which all known anti-obesity remedies had been tried unsuccessfully A. E. Spaulding (*St. Paul Med. Jour.*, Oct., 1901) made an elliptical incision on

each side of the median line, from just below the breasts to the center of Poupart's ligament. He removed the integument and fat six inches thick down to the abdominal muscle-sheath, and closed each of the wounds with twenty-five deep silkwormgut sutures. A marked improvement in the general condition has been noted during the two months which have elapsed since the operation.

M. Sig. Half to one teaspoonful in water, repeated if necessary three times a day.—Bossi in the "Revue d'Obstetrique et de Gynécologie."

Ovarian Opotherapy.—Fresh ovary taken by mouth has proven efficient in relieving the mental depression, insomnia, vertigo, hot flashes, palpitation, pelvic pains, etc., which sometimes follow removal of the ovaries. The raw ovary of the sheep, sow or cow should be obtained fresh every day, and it should be remembered that most butchers cannot tell an ovary from a gland. It may be taken by mouth, and as many women and girls object to eating ovaries if they know what they are, it may be necessary to have some member of the family disguise them. Ovaries may be dried without harm at 30° C. (86° F.), powdered, and mixed with bouillon or milk.—E. Vidal in *Le Progrès Médical,* Sept. 7, 1901.

Cæsarian Section.—This is not a difficult operation, writes J. W. Andrews (*St. Paul Med. Jour.,* Oct., 1901), and with present methods its mortality is not high. There is very little danger of troublesome hemorrhage. To ensure proper drainage a strip of iodoform gauze should be carried through the cervix, but not up into the body of the uterus, as this might excite contractions and endanger the line of stitches. Owing to the rapid involution of the uterus the stitches could become loose, but this risk may be avoided by a row of stitches through all the tissues except the mucous membrane, and a second row of closely-placed Lembert stitches making peritoneal apposition. Symphysiotomy is more difficult to perform, and not less dangerous. Craniotomy is generally an operation of last resort, is clumsy and not devoid of danger, and the child is not saved.

Glaucoma.—The medical treatment consists of myotics, such as eserine or pilocarpine, as these lessen tension. They should never be used in greater strength than one per cent.; eserine should be dissolved by preference in oil, as it then does not undergo change and does not cause painful spasm; the best salts of pilocarpine are the nitrate and salicyate. The myotics are aided by leeches to the temple, hot compresses, purgatives, etc., but these means are all of temporary benefit only, and are not curative, so recourse must be had to paracentesis, sclerotomy or iridectomy. At the onset of acute glaucoma, order escerine instillations, three times a day, leeches, hot mustard bath, etc. Never employ atropine. If the tension is so great that the anterior chamber is obliterated, precede with sclerotomy or better with puncture of the vitreous by Graefe's knife. Operation is effective only in acute or subacute glaucoma. Hemorrhage and tumor should be ruled out before operation. With tumor the tension presents extensive fluctuations. Iridectomy is generally good if performed early; if late it may lessen the pain and tension without improving vision; in the aged it is unfavorable. In every case after the operation, myotics must be continued for months or years, for they are of benefit even though the iris sphincter is not intact. In simple chronic glaucoma, operation is useless or harmwul, iridectomy sometimes being followed by rapid diminution of vision. The severe cases require eserine, but in mild cases pilocarpine will do. Quinine sulphate and potassium iodide may be given internally, and all medication must be continued for a long time.—F. Terrien in *Le Progrès Médical,* Aug. 24, 1901.

Toast.—The object of making toast is to convert the starch into dextrin, giving the starch its first step toward digestion and the agreeable toast flavor. The bread must first be thoroughly dried, or it cannot be brought to 400° F., the dextrinizing temperature. Toast is therefore crisp to the center and a golden brown. It can be easily broken, is quickly moistened by the saliva, and, what is an advantage with invalids and children, it requires mastication.—H. V. Sachse in "How to Cook for the Sick."

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the Medical News will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

SATURDAY, NOVEMBER 16, 1901.

FUNCTIONAL DISTURBANCES OF DUCTLESS GLANDS.

At the October meeting of the Harvard Medical Society, an account of which will be found in our society proceedings for this week, Dr. John G. Perry discussed a series of cases the symptoms of which had been considered as rhumatic in origin, but as the result of the therapeutic test were evidently due to functional derangement of the thyroid gland. This represents an idea in nosology that has not as yet received its proper share of attention.

While in theory it is not hard to recognize the possibility of functional derangements of ductless glands, the effect of these organs under pathological conditions is so recent an introduction to practical medicine that only complete cessation of function, as induced by serious organic lesions, has been considered worthy of careful study. There seems no good reason to doubt, however, that especially in predisposed individuals—that is, in those who are naturally possessed of ductless glands only just capable of maintaining sufficient function to preserve health, some systemic disturbance might easily decrease such function and give rise to anomalous symptoms.

In Dr. Perry's cases he assumes that enduring inhibition of thyroid secretion was brought on by fright or intense emotional strain. In all a definite uniform symptom-complex was present. Four symptoms were constant; a painful condition of the joints resembling the neuro-arthropathy described by the late Charcot, headache, a weak and rapid heart, and in women a distinct tendency to menorrhagia. In practically all of his cases Dr. Perry found the usual depression above the sternum obliterated, as if there were enlargement of the lower median portion of the thyroid gland, although there was not true goiter nor exophthalmos. The symptomatic condition was rapidly improved by the administration of from ten to twenty grains of thyroid extract per day. The patients, as a rule, developed no symptoms of intolerance for the remedy. In one series of cases three generations of the same family were involved and the lowered functional activity of the thyroid was probably due to hereditary influences.

In recent years more and more attention has been given to such incomplete types of disease as have been touched upon by Dr. Perry. Atypical abortive cases of Basedow's disease are not rare. Without the exophthalmos or the goiter there may be recurring intervals of rapid heart action, with some muscular tremor and intestinal derangement, usually alternating constipation and diarrhea that betray the character of the disease. These affections are often ascribed to anomalous neurasthenia.

Rheumatism and neurasthenia are words that may be readily used to cover the disinclination to search farther for the causes of annoying symptoms. Another affection that in its incipiency may easily be placed in the category of neurasthenia is arteriosclerosis. The precocious degeneration of arteries often gives that tendency to widely distributed symptoms with multiform discomfort that is presumed to be the principal pathognomonic sign of nerve weakness or hypochondriasis. Joint structures very early give discomfort if there is diminished blood-supply or if the presence of alien substances in the circulation disturbs the normal metabolism of their tissues, which, because of their delicate adjustment and frequent use, require to be kept at a certain acme of nutrition.

There is no doubt that the term rheumatism has been very much abused. Dr. Perry's group of cases is of special interest for the reason that it calls renewed attention to the necessity for

more discerning diagnosis in many affections too easily denominated rheumatic. The therapeutics of atypical and chronic rheumatism remains one of the opprobria of medicine and a rich field for the quack and the proprietary remedy, mostly because of the failure to differentiate accurately from each the various affections that are unwarrantably grouped under the heading rheumatism because they present as a prominent symptom discomfort or pain in the use of the joints. A confirmation of Dr. Perry's observations by other clinicians will give us a noteworthy advance in nosology in the recognition of functional disturbances of ductless glands as distinct entities, and will besides achieve that eminently desirable object of adding to our therapeutic armamentarium.

CHRISTIAN SCIENCE A BUSINESS.

CHRISTIAN science, according to a Nebraska Supreme Court decision (Buswell *vs.* the People) is not a religion when practised for the purposes of gain. Ezra M. Buswell, who had never had a medical education and had not received a certificate, was convicted of violating the Medical Practice Act. Buswell, a believer in "Christian science," to whom sick people came, would put his hands upon them and urge them to believe that they were cured. After prayers and exhortation the afflicted persons would sometimes declare that they were cured and express satisfaction with the treatment. It was shown that Buswell frequently received compensation for this treatment. Buswell did not deny that he had applied the "principles" of "Christian science" in treating sick persons, but defended himself on the ground that his doings were simply religious acts, and that no law could be passed interfering with the enjoyment of liberty in religious matters. The Supreme Court held that neither the pretense of worship nor the performance of any other duty should exonerate the defendant from the punishment attached to the violation of the law.

The Court quoted several verses from the eighth chapter of the Acts of the Apostles in which Simon, the Samaritan sorcerer, is rebuked for endeavoring to purchase the power of healing which the Apostle Peter possessed. "And when Simon saw that through laying on of the Apostle's hands the Holy Ghost was given, he offered them money, saying, 'Give me also this power that on whomsoever I lay hands he may receive the Holy Ghost.' But Peter said unto him, 'Thy money perish with thee because thou hast thought that the gift of God may be purchased with money.'" The incident of the receiving a reward by Gehazi from Naaman, after the latter had been cured by the prophet Elisha, and his consequent punishment are quoted from II. Kings v, 26, 27. "The leprosy therefore of Naaman shall cleave unto thee and unto thy seed forever. And he went out from his presence a leper as white as snow."

In many States, however, noticeably in Illinois, after the repeal of the excellent Medical Practice Act (under which the late Dr. J. H. Ruch achieved such marked success), "Christian science" was given a status which annulled all the good effects of the principle enunciated by the Nebraska Supreme Court.

TUBERCULOSIS FAKIRS.

THERE is rarely a stirring medical subject discussed, but the quacks, who are always alert to turn popular interest to their own advantage, begin to do a little song and dance on their own account.

The announcement made by Koch at the London Congress, seeking to modify the widely-accepted view that tuberculosis can be contracted by drinking the milk or eating the flesh of tuberculous cows, has given the tuberculosis fakirs a brass band and an audience. This is their opportunity. The fakirs are so-called physicians who perform startling experiments, in the daily press, that outrival Koch. Reporters' interviews and testimonies of patients all contribute to swell the interest, and the subject being legitimately started by the London Congress bears the stamp of respectability.

One man in New York, claiming to be a homeopathic practitioner, announces in the reading columns of one of the best dailies that he has a cure for consumption. He uses a mysterious preparation of his own, which is said to be a preparation of cacodylate of soda, which is being extensively tried in the hospitals abroad. For each treatment of this patent charm he is said to charge $500.00, but so charitable is this benefactor of the race that the newspaper accounts say that he is thinking of giving it free to the public.

The Medical Society to which he belonged has expelled him, and the hospital in which he says he performed his experiments has asked his resignation and has declined to acknowledge or certify any of the favorable results he claims. These formal denouncements in medical

circles do not prevent him from using the name of the hospital on his circulars, or of representing himself as being an interpreter of Koch and the spirit of modern science. With prospective philanthropy on the horizon, he may continue to charm the public into giving him large sums for a well-known and questionably useful remedy for some time to come.

Another method of diverting the general interest in tuberculosis into the special channel of self-aggrandizement is the somewhat startlingly advertized experiment of a certain Brooklyn physician who has inoculated a patient with tuberculous matter from a cow. The attitude is that of the brave man and the noble woman who risk, the one his reputation and the other her life, for the sake of scientific truth.

That the physician promises to cure the patient if she is inoculated and that her faith in his power is sufficient to enable her to calmly take the risk are, we feel, no justifiable basis for the proceeding. No sure cure has as yet been found for tuberculosis, and a man's faith in his own power, no matter how convincing it may be to his patient, cannot convince us that the woman is sensible in taking the risk acquiring a disease for which no one, save a fraud, can guarantee a cure.

That the advertizing element in this case may be purely accidental does not lessen the harm that such discussions bring to those that are in the incipient stages of the disease. A cure! a cure! is their cry, and so long as the public is looking for a cure our task in attempting to save their lives by the patient upbuilding of strength through diet and climate is hopeless.

Success in advertising quackery seems to be a very uncertain matter, dependent neither on extensive capital nor on skill in "flarehead" advertisements. A "rupture cure" quack who had organized a syndicate and plastered the prominent daily journals east and west with advertisements has just confessed in the bankruptcy court to liabilities of $58,000 and no assets. He secured the usual National Bank endorsement by investing in National Bank stock, and had wrecked two National Banks by inducing them to discount notes of the "no cure no pay" contract type. Many a National Bank in the West has had to pass to profit and loss thousands of dollars in similar notes. At one time, in 1893, an Indianapolis bank was nearly dragged into a prosecution for misuse of the mails through its discounting such notes for a local "Institute." The "note" is in the semblance of contract not to pay unless cured, but has been held to be a promissory note. The business "acumen" shown in the discounting of such notes and in loans on patent medicine and "medical institute" stock underlay the downfall of many a Southern and Western National Bank in the era between 1893 and 1899.

ECHOES AND NEWS.

NEW YORK.

Craig Colony Prize Awarded.—At a meeting of the Board of Managers of Craig Colony, held at Sonyea, N. Y., on October 8, 1901, the report of the Prize Committee, consisting of Drs. G. W. Jacoby, Pearce Bailey and Ira Van Gieson, was approved, and the prize of $200 was awarded to Dr. Carlo Ceni of Pavia, Italy. The successful essay, the title of which is "Serotherapy in Epilepsy," will shortly be published in the Medical News. As announced in the News of October 19th, the prize is again offered for universal competition.

Jewish Hospital for Brooklyn.—Articles incorporating the Jewish Hospital of the Borough of Brooklyn were filed November 9th, according to the *Evening Post,* with the Secretary of State. Medical and surgical aid will be furnished without regard to creed or nationality. The directors include Aaron Aaron, Jacob Brenner, Jacob Fuhs, M.D., and Nathan S. Jonas.

New York State Medical Association.—A special meeting of the Fifth District Branch of the New York State Medical Association will be held at the Palatine Hotel, Newburgh, N. Y., on Wednesday afternoon, November 20th. Important papers will be presented by Dr. John B. Deaver of Philadelphia and Drs. Charles E. Quimby and William Rice Pryor of New York. These papers will be followed by discussions. A large attendance of physicians is anticipated from among the members residing in the Fifth District Branch, which includes the Counties of Dutchess, Kings, Nassau, New York, Orange, Putnam, Queens, Richmond, Rockland, Suffolk, Sullivan, Ulster and Westchester. For the accommodation of the physicians in Manhattan who wish to attend this meeting, a special car will be attached to the 11.50 a. m. train, on the West Shore Railroad, Weehawken Ferry. Luncheon will be served at Newburgh at 1.45 p. m. The meeting is called for 2.30 p. m. All physicians are cordially invited to attend.

New York State and County Civil Service Examinations.—Open competitive examinations for positions in New York State and County Departments and Institutions will be held about December 7, 1901, in Albany, Amsterdam, Auburn, Binghamton, Buffalo, Elmira, Hornellsville, Ithaca, Jamestown, Kingston, Lockport, Malone, Newburg, New York, Og-

densburg, Olean, Oneonta, Plattsburg, Poughkeepsie, Rochester, Sandy Hill, Syracuse, Utica, and Watertown, for the following positions: Assistant, Antitoxin Laboratory, Department of Health, $720; open to women only. Assistant Bacteriologist, Department of Health, $500 for half time; open to licensed physicians only. Director of Pathological Institute, State Commission in Lunacy, $5,000; open to non-residents subject to the provisions of Regulation X. Physician, Third Grade (including Junior Physician), State Hospitals, usual salary $900 and maintenance; open to licensed practitioners who have had at least one year of hospital experience. Applications for these positions must be filed in the office of the commission on or before noon of December 2d.

Sale of Harmful Drugs.—At a meeting of the Society of Medical Jurisprudence last week, Dr. W. H. J. Sieberg read a paper on "The Adulteration of Drugs and the Sale of Harmful Proprietary Medicines." He said that drugs were adulterated and substituted much more extensively and with more serious effects than was generally supposed. "The crime committed against those stricken with disease is so abominable," he said, "that I cannot properly characterize it. I believe the State should compel all proprietary medicines to be submitted to a board of expert chemists and botanists who should determine whether a dangerous percentage of poison was contained as an ingredient and if so refuse to allow its sale. Cupidity is to be found in the drug trade as well as in other places," he said. He found that both adulteration and substitution were largely practised in this city and State. In speaking of the unrestricted sale of poisons he said that a "purely vegetable tonic recommended for inebriates" contained 41 per cent. of alcohol. Many such proprietary medicines, he declared, contained poisons the sale of which if they were not sold in sealed packages would send the druggist to jail. Cough medicines contain opium and morphine in unknown quantities; face lotions, warranted purely vegetable and harmless, poison the user with lead or mercury. The druggist sells all these, and there is no law to stop him because he is supposed to be ignorant of the contents of the packages.

Meeting of Charities and Correction Conference.—The second New York State Conference of Charities and Correction will be held in New York November 19 to 22. The membership of the conference is made up of persons who are interested in public or private charitable or correctional work in the State. The topics for discussion are grouped in several departments under the charge of the following committees: "Hospitals, Dispensaries, and Nursing," Dr. Stephen Smith, New York, Chairman; "Sanatoria for Consumptives," Dr. John H. Pryor, Buffalo, Chairman; "The Mentally Defective," Dr. A. E. McDonald, New York, Chairman; "The Care of Defective, Dependent, Delinquent, and Neglected Children," Dr. F. Park Lewis, Buffalo, Chairman; "The Institutional Care of Destitute Adults," Mr. Clarence V. Lodge, Rochester, Chairman; "The Treatment of the Criminal," the Hon. George McLaughlin, Albany, Chairman; "Politics in Penal and Charitable Institutions," Mrs. Charles R. Lowell, New York, Chairman; "The Care and Relief of Needy Families in their Own Homes," Mr. Frank Tucker, New York, Chairman; "Improved Housing," Mr. Edward T. Devine, New York, Chairman.

Manhattan Dermatological Society.—A regular meeting was held on Friday evening, November 1, 1901, at the residence of Dr. R. Abrahams. Dr. Wm. S. Gottheil presided.

Dr. R. Abrahams presented a child of eight weeks with an *acute generalized seborrheal eczema.* The lesions were macular and diffuse; the palms and soles were free. Dr. J. Sobel agreed with the diagnosis. The lesions were too highly inflammatory for syphilis and stigmata of that disease were wanting. Dr. Oberndorfer excluded syphilis. Dr. Gottheil remarked that macular lesions in seborrheal eczema are unusual. Dr. J. Sobel showed a child of two and a half years with a *chronic papular urticaria* of the face, arms, thighs, buttocks and legs; the lesions had existed with periods of remission for a year and a half. Itching was intense, the inguinal glands were enlarged and subsequent infection of some papules by scratching had given rise to pustules. The interdigital regions were free. Such cases were frequently considered prurigo mitis.

Dr. Bleiman agreed with the diagnosis, excluding both prurigo and scabies. Dr. L. Weiss believed that such cases were better termed strophulus infantilis (Blaschko). This condition is persistent, obstinate and often the forerunner of prurigo. He is of the opinion that this case will eventually develop prurigo. Dr. Oberndorfer inclines toward a diagnosis of chronic papular urticaria. Dr. Gottheil does not think that scabies can be excluded. Dr. Abrahams considers it chronic papular urticaria. Pilocarpine in daily doses of gr. $^1/_{12}$ is advised.

Dr. Bleiman presented a boy of eleven years with *prurigo.* Lesions on the extensor surfaces began at two years of age and have persisted since, never disappearing entirely, but improving in the summer and spring. Scalp is free, but face shows papular lesions. Prurigo buboes are absent. Treatment has been given for a long time. Dr. Geyser remarked that the lesions may be the remains of a prurigo. Dr. Sobel thought that in view of active treatment a positive diagnosis at present could not be made. He would prefer to see the lesions in the untreated stage before venturing a diagnosis of prurigo. Dr. Oberndorfer considered it a chronic papular eczema; such cases often last for many years, one of his own being of twelve years' duration. Dr. Weiss stated that this was a positive case of prurigo. The existence of the lesions from infancy and the involvement of the extensor surfaces point toward that diagnosis. The skin is infiltrated, and

while buboes are absent this does not speak against it. Dr. R. Abrahams said that the picture was not one of prurigo. In nine years typical lesions ought to exist all over the body. He considers it chronic eczema. Dr. Gottheil has seen the patient when the flexor surfaces were affected; he considers it chronic eczema.

Dr. Gottheil presented a woman of sixty-four years with *rhinoscleroma* of the nose and lip. The alæ nasi had the hard, cartilaginous, ivory hardness so characteristic of this condition. The hard palate was also involved. Despite the statements in books this case shows ulceration. The possibility of other parts being involved was mentioned. Dr. Geyser remarked that radiotherapy would only hasten the end of the patient. Dr. Sobel had previously observed this case in the service of Dr. C. W. Allen. In another case seen in the same service the lesion had encroached upon the postnasal space to the larynx, necessitating a tracheotomy. Ulceration certainly occurs. Rhinoscleroma may occur primarily in the tonsil, in which case differentiation from chancre and cancer becomes necessary. Dr. L. Weiss remarked that ulceration may occur when the vitality of the tissue is encroached upon by pressure.

Dr. L. Weiss presented a case of *keratosis follicularis* of the forearms.

Dr. Oberndorfer presented a young man with multiple lesions of *molluscum contagiosum of the penis.* The situation was interesting and rare. In children the lesions often become infected and cause pustulation. The condition is both auto- and hetero-inoculable. Dr. Bleiman has observed similar cases in children, but always with other lesions on the face, chin or body. Dr. R. Abrahams has seen the condition in several members of a family. Dr. Gottheil observed one case in which numerous mollusca were situated on the penis and scrotum. Subsequent infection may give rise to furuncular lesions.

Dr. R. Abrahams presented a man of fifty-seven with *atrophia cutis propria* of both lower extremities. Forty years ago eczematous lesions were observed in the popliteal space; later similar lesions appeared at the ankle. This was followed by atrophy, varicose veins and ulceration. Dr. Sobel stated that at first scleroderma suggested itself. He considers it an atrophy due to a tropho-neurosis. Dr. Oberndorfer considers it a clear case of atrophia cutis propria. It now presents atrophy of the cutis propria, varicose veins, and ulceration. There is in all probability no relationship between the varicose veins and atrophy, otherwise atrophy of the skin would be more commonly observed. It is a tropho-neurosis of some kind. Dr. Gottheil has observed but one similar case. In this case the erythema at the edges points to an inflammatory condition.

Dr. Gottheil showed photographs of cellulitis of the lip, secondary sarcoma cutis, generalized lichen planus, lichenification in old eczema, erythrasma of the buttocks, dysidrosis, and erythema multiforme.

PHILADELPHIA.

University of Pennsylvania.—At the trustees' meeting last week the following changes were made in the faculty: Dr. Charles Mills was appointed clinical professor of nervous diseases, vice Dr. Horatio Wood, resigned; Dr. W. G. Spiller, assistant professor of nervous diseases, and Dr. Charles Burr, professor of mental diseases.

Mutter Lecture.—The Committee on the Mutter Museum of the College of Physicians of Philadelphia wish to announce that the Mutter lecture for the year 1901 will be delivered on Tuesday, December 3, 1901, at 8 p. m., in the Hall of the College of Physicians. Dr. Harvey Cushing of Baltimore will deliver the lecture, the subject being "Some Experimental Observations Relative to the Surgery of the Nervous System."

Testing of Diphtheria Antitoxin for the Tetanus Bacillus.—In view of the deaths in other cities from tetanus following the use of infected diphtheria antitoxin, the Board of Health has taken measures to guard against such an occurrence in this city. Orders have been issued that all the antitoxin supplied by the city shall be tested to determine the presence or absence of the tetanus bacillus.

Increase in Almshouse Expenses.—The estimates for maintenance for the Philadelphia Almshouse are about $100,000 more for the coming year than for the past one. Part of this is due to proposed additions to the force of employees, but the greater part is caused by an increase in the price of provisions and an increased population. The sum of $365,000 is asked for new buildings, including a pavilion for consumptives, a clinical amphitheater, obstetrical and gynecological ward, pavilion for nervous diseases, and a pavilion for general medicine.

Miners' Petition for New Hospital.—A committee has been chosen by a meeting of miners at Pine Grove to petition the Legislature for the establishment of a miners' hospital on Broad Mountain, ten miles from Pine Grove. It is claimed that a hospital is needed for that section comprising portions of Lebanon, Schuylkill and Dauphin Counties, which are so far removed from the hospital at Ashland that fatalities result from accidents when the patients could be saved by more immediate hospital facilities. The population of the section in question is about 50,000.

Dr. Osler a Guest of the College of Physicians.—Dr. William Osler was the guest of honor at the meeting of the College of Physicians, November 6th. Dr. Osler gave a short sketch of Sir Thomas Brown and his writings, the purpose of the sketch being to give a brief history of the man and his productions and "to introduce to their final resting place" an almost complete collection of the various editions of the books, which are ultimately to become the property of the College. Lantern slides of buildings, etc., associated with the life of Sir Thomas Brown, and of the title pages of the various edi-

tions of his writings, were shown. Sir Thomas was characterized by Dr. Osler as being one of the three great *littérateurs* of the medical profession.

To Protect Rivers from Pollution.—The Supreme Court of the State has recently handed down a decision which is believed to be of great importance to the cities of the State. The suit in question was that brought by a flour-mill company against the Lehigh Coal and Navigation Company, which caused a loss of water power by filling the stream above with dirt and refuse. The Court maintains: "It is not to be doubted that an injunction is the appropriate remedy for the prevention of trespasses and nuisances, which, by reason of the persistency with which they are repeated threaten to become of a permanent nature." It is believed that this ruling will have considerable influence in deciding the litigation brought by City Solicitor Kinsey to protect this city's water-supply from contamination by the filth which industrial establishments and coal companies persist in dumping into the Schuylkill River.

Philadelphia's Filtration Plant.—Bids have been asked for constructing what is said to be the largest filtration plant in the world. It is to be located at Tordesdale and receive its supply from the Delaware River. The design is for fifty-five filter beds, with a capacity of 100,000,000 gallons of water daily, so placed that fifty-five more can be ultimately added. The cost will be in the neighborhood of $3,000,000. West Philadelphia and some of the northern suburbs will still continue to receive their supply from small filtration plants using Schuylkill water. The beds will not differ in construction from those already in use except that no sedimentation basin will be provided, the clearness of the Delaware water making such preliminary work unnecessary.

Pseudoleucemia and Lymphatic Tuberculosis.—At the November meeting of the College of Physicians Dr. Joseph Sailer reported four cases of apparent pseudoleucemia due to lymphatic tuberculosis, or Sternberg's disease. Three of the cases have proven to be such by autopsy. He believes that this is the condition in all the cases of so-called Hodgkin's disease. In the discussion Dr. Osler said that the term Sternberg's disease was not used to include all cases of lymphatic tuberculosis. Tuberculous adenitis has long been recognized as a distinct affection. What Sternberg has shown is that certain cases which clinically and anatomically are those of Hodgkin's disease are by inoculation experiments proven to be tuberculous. Dr. Osler holds that there is a true Hodgkin's disease apart from these cases of Sternberg's description. Dr. John H. Musser stated his belief that Hodgkin's disease in the larger number of cases is lymphatic tuberculosis. Dr. Alfred Stengel said the matter was reduced to the question of whether there was a disease related to leucemia apart from lymphatic tuberculosis. He reasons that if leucemia is not tuberculous in nature, then there is a true Hodgkin's disease. He believes the attitude of the profession should be that of expecting more proof from those who say that Hodgkin's disease is tuberculous in nature. Dr. James Tyson said that the cases reported by Dr. Sailer showed an absence of superficial gland involvement, as in the groin, axilla, etc., which is usually seen in cases of Hodgkin's disease. Dr. Sailer stated that the glands in these cases were not softened nor in any other way like those in general lymphatic tuberculosis. He called attention to a recently reported case of leucemia which was tuberculous in nature. He thinks the burden of proof lies with those who hold to the opinion that there is a true Hodgkin's disease. The weight of evidence is against that view.

CHICAGO.

State as Antitoxin Maker.—Dr. Herman Spalding favors the State control and manufacture of antitoxin in view of the recent deaths from its use in St. Louis. He also suggests that the State supply the serum at cost, as the most effective way in which the poorer grades of the article may be driven out of use. There is little doubt that the recent deaths caused by impure antitoxin in St. Louis would not have occurred had the serum used been properly manufactured and tested. Dr. Spalding says there has been a large profit in the manufacture of the article, and many cheap grades have been placed on the market. If the States would take up the manufacture of the serum, say at their State universities, and provide for the sale of the same at cost, he thinks it would solve the whole problem. Every State should enact such a law and enforce it. The law should provide for State supervision of the manufacture of the article, which should be prepared by the best chemists at the universities and its purity assured.

Gift of Two Beds to St. Luke's Hospital.—Edward Finley and wife have conveyed real estate to the value of $10,000 to St. Luke's Hospital, and in return the Hospital is to endow two new beds to be called the "Edward and Dorcas A. Finley Beds." Mr. and Mrs. Finley are to have the right of selecting patients for the beds whenever they are vacant, and if occupied they are to have the preference over any other applicants. On their deaths, the right to make nominations is to go to some person designated by them.

Swedish Award to Dr. Senn.—News has been received from Stockholm that among the persons whose names are under consideration by the committee in charge of the award of the Noble Prizes are Dr. Nicholas Senn of this city and Thomas A. Edison of New York. Dr. Senn will be in the group of medicine and surgery and Mr. Edison in the group of chemistry. The prizes will be awarded on December 10th, and are five in number—physics, chemistry, medicine, literature, and promotion of peace.

Investigation of Insane Hospital at Dun-

ning.—This institution is undergoing an investigation at the present time. Some of the charges that were made may be epitomized briefly as follows: That by reason of the lack of heating in the cold days of early October, half a dozen insane patients became sick with pneumonia and one death resulted; that several hundred insane patients are caused great suffering by being compelled to walk in cold weather from the detached wards to the main dining-room, although their clothing consists of nothing but overalls, thin jackets, slippers and straw hats, without any underwear or overcoats. The distance is five thousand feet, and the trip must be made for each meal, even when the thermometer is below zero. That the supply of clothing and bedding has been allowed to fall so low that even inside the wards there is often great suffering. That there are no proper facilities for caring for the sick, and that there is not one trained nurse in the institution. That the drug supply is kept down to the lowest limit, so that often needed remedies cannot be given when the physicians prescribe them. That the food, although of good quality, is carelessly cooked and often spoiled in the kitchen. That while the exposed portions of the wards for the insane are scrupulously clean, any amount of filth is permitted where it will not be noticed, and that, especially in bathing the patients, sanitary precautions are not taken. That the consumptive patients are allowed to mingle with the insane, and that a number of cases of tuberculosis have developed among the latter because of this contact. It will be interesting to watch the outcome of this investigation.

Traffic in Cadavers.—Dr. F. M. Schoenleber has been arrested on the charge of shipping dead bodies from this city to other States. He will be prosecuted by the State Board of Health under the statute forbidding the removal of human remains from the State without a permit from the proper health officials.

Not Guilty.—On October 31st Judge Tuley instructed the jury to bring in a verdict of not guilty in the case against Dr. Arthur R. Reynolds, Commissioner of Health, and Matthias Brand, formerly a member of the Board of Health, in the suit of Mrs. Mary E. Moore, who sought to recover $25,000 damages on account of alleged detention in the isolation hospital.

Aneurism of the Aorta Simulating Mediastinal Abscess.—Dr. Otto T. Freer presented this case to the Chicago Medical Society, November 6th. The patient was a negro, aged forty-two years. He gave a history of pain under the sternum, on the left side of the thorax and between the shoulder-blades, which had existed since about the first of July. The patient suffered from constant dyspnea, which began suddenly in August after a paroxysm of coughing. A few days later he coughed up a little blood. Since this time the cough and profuse expectoration have been, with the dyspnea, the main features of the disease. Observation of the patient at the Presbyterian Hospital for two months showed but one day when he had a temperature above the normal. The dyspnea was constant, but varied in degree and became alarming when there were paroxysms of coughing, suffocation often seeming imminent. Examination showed dulness under the manubrium sterni and on either side of it. This area of dulness extended downward until it merged into that of the heart. The apex beat was displaced downward to the sixth interspace. Tracheoscopy with the aid of sunlight showed a narrowed place in the trachea just above the bifurcation, while the windpipe was seen to be pushed over to the right. There was no paralysis of the recurrent laryngeal nerve nor any other symptoms of nervous compression, but some dilatation of the veins of the face, neck and arms indicated moderate compression and stenosis of the superior vena cava. The continued expectoration of large amounts of material that was more purulent than mucous in character, the freedom of the other intrathoracic organs, with the exception of the trachea and vena cava, from pressure, together with the great degree of the tracheal stenosis, made it seem probable at first that the compressing mass was small, intimately connected with the trachea and most likely an abscess of the mediastinal flamed its wall and that was discharging into its glands that had perforated the trachea, had inlumen.

The absence of fever, marked improvement resulting from rest in bed, the severity of the pain, the unvarying character of the symptoms during the long period of observation and especially the shadow characteristic of aneurism shown in the radiograph, finally lead to the adoption of the diagnosis of aneurism of the aortic arch. Further proof of its existence was furnished by the appearance later of distinct pulsation in the jugular. Bruit and tracheal tugging were absent.

Secondary Tuberculous Cystitis Colli.—At the same meeting Dr. L. E. Schmidt reported a case, the patient having been presented to the Society four months previously. He suffered from frequent urination both day and night, with tenesmus. Urine was very turbid. Frequently had terminal hematuria; constant loss in weight, appetite, and gradually became weaker, until he was finally obliged to quit work and confine himself to bed. Rectal examination revealed a nodulated prostate, and the secretion from here showed tubercle bacilli. On cystoscopic examination a secondary tuberculous cystitis colli was diagnosed. Local treatment of prostate, both per rectum and urethra, was made, general constitutional treatment instituted, and many tubercles around the internal ureteral opening and within the trigonum were cauterized with the aid of the Kolischer cystoscope. The cystitis colli has almost disappeared, likewise the symptoms, and the patient has gained thirty-one pounds in weight. Dr. Schmidt reported two other interesting cases.

GENERAL.

Russia and its Physicians.—The number of male physicians in Russia is 14,784; that of female physicians is 624, but it will soon be larger, as there were last year 869 female students in the Medical Institute for Women.

Indian Territory Medical Association.—The next meeting will be held at Muscogee, Indian Territory, the first Tuesday and Wednesday in December.

Consumption Cars.—In consequence of the increasing demands upon the Western and the Southern railroads for transportation for consumptives, the Transcontinental Passenger Association has prepared a plan, for the consideration of all the railroads, looking to the provision of a special consumption car, or ward, on each train. This subject will be acted upon at a meeting of the general passenger agents to be held in St. Louis on November 19th.

Church Hill Medical Society.—The program for the winter of 1901-'02 is as follows: "Pneumonia in Infancy and Childhood—Its Recognition and Treatment," by Dr. Garcin; "Broncho and Lobar Pneumonia in the Aged—Recognition and Treatment," by Dr. Parker; "Pleurisy—Its Varieties, Recognition and Treatment," by Dr. Blankingship; "Croup, Simple and Membranous —Recognition and Treatment," by Dr. Beazley; "Acute Rheumatism in Childhood and Adults—Its Symptoms and Treatment," by Dr. Virginius Harrison; "Acute Tonsilitis—Varieties, Symptoms and Treatment," by Dr. Barksdale; "La Grippe, Complications, Varieties and Treatment," by Dr. St. J. Oppenheimer; "Neuralgia, Varieties, Recognition and Treatment," by Dr. Gay; "Acute Bronchitis—Recognition and Treatment," by Dr. Cosby; "Diphtheria—Recognition and Treatment," by Dr. C. W. Massie; "Measles—Diagnosis and Complications, and Treatment," by Dr. Hord; "Chicken-Pox—Diagnosis and Treatment," by Dr. Collins.

New Hospital Planned by St. John's Guild.—The thirtieth annual meeting of St. John's Guild was held Tuesday evening, November 12th, at the Berkeley Lyceum. A general review of the work of the past year appeared in the reports of the various officers. It was announced that after a long-continued investigation into the needs of New York for a convalescent hospital, the trustees have decided to establish such an institution on the Guild's property at New Dorp, S. I. The hospital will be open the entire year for the care and treatment of women and children during convalescence. Funds sufficient to carry out the idea are not yet in the hands of the trustees, but tentative plans have been prepared, and were illustrated by stereopticon at the meeting last night. They call for fireproof buildings, specially adapted to the purpose, which will take the place of the frame building now used as a summer hospital.

Sells Diplomas to Midwives.—Dr. Charles P. Kreizer, who has been arrested repeatedly for being concerned in suspicious schemes connected with the practice of medicine, was summonsed to Jefferson Market Police Court November 12th by Agent Agnew of the Children's Society, who is also a Board of Health Inspector. Inspector Agnew told Magistrate Meade that Kreizer was president, faculty and board of examiners of the "Columbia College of Midwifery," which had one room on the ground floor of a tenement at 333 West Thirty-fourth Street and a clinic in equally humble quarters at 242 West Thirty-third Street. Women anxious to become midwives were induced to take a "course" of three hours' weekly instruction for three months and to pay as high as $100 for an elaborate diploma with an impressively large seal. Kreizer could not be charged with any specific fraud and was discharged.

The New York Academy of Medicine.—A stated meeting will be held at Hosack Hall, Thursday evening, November 21st, under the auspices of the Section on Medicine. The following program is planned: "Some Remarks on the Diagnosis of Cirrhosis of the Liver," by Dr. James C. Wilson of Philadelphia; "The Operative Treatment of Ascites in Cirrhosis of the Liver, by Dr. George Emerson Brewer of New York; general discussion by Drs. F. Tilden Brown, Morris Manges, George L. Peabody, Beverley Robinson, Andrew H. Smith, and others. These papers will appear in the MEDICAL NEWS.

CORRESPONDENCE.

OUR LONDON LETTER.

(From Our Special Correspondent.)

LONDON, November 2d, 1901.

REOPENING OF THE MEDICAL SCHOOLS—DECLINE IN THE NUMBER OF ENTRIES—THE MEDICAL SOCIETIES — INOCULATION AGAINST TYPHOID FEVER—THE HEALTH OF THE KING—DIAGNOSIS IN ABSENTIA.

THE reopening of the medical schools in October used not many years ago to be made the occasion for a ceremonial display of some kind intended to impress the newly-captured neophytes. The chief feature in the "function" was an inaugural address in which the orator rhapsodized to the best of his power on the nobility of the medical profession and gave much good advice to the students. These homilies were for the most part so dull that the preacher might have been excused if he had gone to sleep in delivering them, as the Duke of Devonshire is said to have done over one of his own speeches. Sometimes, however, what dramatic critics call "comic relief" was provided when a man who, it was known, would stoop to pick guineas out of the gutter unctuously denounced the pursuit of filthy lucre and urged his guileless hearers to look upon the practice of medicine as a priesthood of philanthropy. Sometimes the orator made a peacock-like display of borrowed—or it might be, purchased—feathers of

classical erudition. A presidential address not long ago delievered before a certain association was horribly stuffed with quotations from various tongues, ancient and modern, to the admiration of the audience, who had no suspicion that these elegant extracts had been supplied by a local schoolmaster. In the Harveian Oration delivered the other day before the London College of Physicians by one of the Fellows of that august body, the speaker seemed to have ransacked every available dictionary of quotations, and it must be admitted that he showed not a little ingenuity in working the tags there found into the patchwork of his discourse. This kind of pedantry is not so common as it was, but it is still considered by pundits of the pompous academic type to be a mark of culture, and they think it necessary to make a display of literary bunting to impress the minds of the vulgar. They act on the principle of Dr. Jobling in "Martin Chuzzlewit," who would fire off some scraps from the Latin grammar that people might speak of him as "a well-read man, a classical scholar."

The introductory address, however, is felt to be a bore, and for some years past it has at one school after another been allowed to fade into nothingness. It still survives in some of the smaller London schools which have a fierce struggle for life, and in some of the newer provincial schools it is used as a means of advertisement.

The entries both at the London and the provincial medical schools this year show a marked and progressive falling off as compared with the two previous years. This diminution is doubtless due to the increased length of the curriculum which now extends over five years and has become proportionately more costly. But the profession in this country is largely overstocked, and a lessened output of doctors is not likely to cause inconvenience to the public.

As a curious illustration of the competition between our too numerous medical schools, it may be mentioned that some of them decline to furnish returns of their entries on the ground that cooked figures are supplied by rival institutions, which thus are made to present a deceptive appearance of superior prosperity. It is hinted by those who ought to know what they are talking about that this manipulation of figures is carried out to such an extent in the London schools as to make the returns quite untrustworthy.

The medical societies are again in full blast. The most interesting debate so far has been one which took place on October 28th at the Medical Society, where Drs. Elliot and Washbourn, who saw much of typhoid fever in South Africa, gave an account of their experience, particularly in regard to the protective value of inoculation. The mortality of the cases which passed through their hands was 13.7 per cent., practically the same as that of the Metropolitan Asylums Board of London during 1900, but almost double that of the Johns Hopkins cases. With regard to the influence of inoculation in averting a fatal issue, they stated that the mortality was 10.7 per cent. in 186 patients who had not been inoculated and 16 per cent. among 25 who had been inoculated. Adding together cases recorded at other hospitals the mortality among 120 inoculated cases was 7.4 per cent. and among 556 not inoculated 10.9 per cent. These figures in the author's opinion did not show that any marked beneficial influence could be attributed to inoculation. With regard to incidence they found that among 224 persons inoculated the proportion attacked was 11.4 per cent. and among 157 not inoculated it was 14.6 per cent. From these figures they drew the conclusion that inoculation was not of any practical value in preventing the disease. As Dr. Washbourn can speak as one having authority in regard to fevers, his opinion will generally be received in this country as going far to discredit antityphoid inoculation. It is not surprising, therefore, that his communication moved Professor Wright of Netley to a certain degree of argumentative pyrexia in defending his intellectual offspring. He pleaded that the adverse conditions in South Africa might have counteracted the good effects of inoculation, and quoted statistics collected by himself which showed that of 8,600 persons inoculated 2.4 per cent. contracted typhoid, while of 41,000 not inoculated the percentage attacked was 5.75. A case mortality of 12 per cent. occurred in inoculated and one of 21 per cent. in the uninoculated. He recommended that in order to give the method fair play every person should be inoculated twice. A small dose of the protective serum gave a temporary immunity and a large dose a period of increased susceptibility followed by a later and more permanent immunity. The experience of Drs. Tooth and Rolleston, also gained in South Africa, was favorable to inoculation, and Surgeon-General Cayley stated that if he were going out to South Africa again, he would be inoculated twice on the voyage out. The most practical contribution to the debate was made by Surgeon-General Muir, Deputy Director General of the Army Medical Service, who said that the question as to the value of inoculation could be decided only on the analyzed results of thousands, not hundreds, of cases.

In a previous letter reference was made to rumors about the health of King Edward, which have been flying about in all ranks of society here ever since his accession. Everywhere one heard it stated with the most positive confidence that His Majesty was afflicted with the same disease which caused the death of his brother-in-law, the Emperor Frederick, and his brother, the Duke of Saxe-Coburg. I pointed out that there was absolutely no foundation for the rumor, which probably had its origin in the appointment of Sir Felix Semon as one of the King's physicians. The appointment of a specialist to such a post was certainly a departure from precedent, but it does not need for its explanation so portentous a hypothesis as that the King is suffering from cancer of the throat. Semon is a German, and as such naturally inspires confidence among the Royal family, who are more German than English. The

Princess Christian persistently puffs Pagenstecher and has sent half the British aristocracy and a large proportion of our snobocracy to Wiesbaden. He was brought over to the Isle of Wight to see Queen Victoria, though the visit was kept dark. In addition to being a German, Semon is a Jew, with his full share of the pushfulness of his ancient race. Opportunity has done much and importunity has perhaps done more in advancing his fortunes; and the result is that he basks in the somewhat inane smile of the sovereign ruler of these realms. Let it be understood that Sir Felix Semon deserves his good luck. He is an excellent physician, though much inferior to Morell Mackenzie as an artistic performer with the laryngoscope, and he has the bump of veneration for the great very highly developed. It is natural, therefore, that he should have found favor in the eyes of the King, but to infer from this that His Majesty has cancer is very bad logic.

The rumors to which I have alluded have for the first time found expression in the newspapers during the past week. A paper which mainly circulates among the working classes published a highly sensational announcement that the King was suffering from cancer of the larynx; that three operations had been performed; that his Majesty's voice gets huskier week by week; that quite recently the King was seized with difficulty of breathing and that an immediate operation had to be performed, which gave only temporary relief, and that serious developments are expected. These statements are evidently taken from a remarkable article in an American newspaper purporting to be written by Dr. Leffingwell Hatch of New York. In that article it is stated that Dr. Hatch was one of the delegates from the United States presented to the King on the occasion of the Tuberculosis Congress, and that from the hoarseness of the King's voice he came to the conclusion that His Majesty was suffering from papillomata of the larynx. For further detailed statements as to operations performed on the King, as to Dr. Leffingwell Hatch having been "unofficially" consulted on the case, etc., the editor of the paper in which the doctor's statement is published appears to be responsible. But the honor of the diagnosis belongs to Dr. Leffingwell Hatch alone, and it is right that he should have it, for it is altogether a record achievement. The doctor, in fact, recognized huskiness in a voice which he could not have heard at the audience—for the excellent reason that he was not there. The official list of the foreign delegates presented to King Edward VII. at St. James's Palace on July 25th is now before me, and the names of those chosen to represent the United States are there given as Professors Osler and Janeway. Dr. Leffingwell Hatch's name is conspicuous by its absence. His article is illustrated with diagrams of the larynx and with what I take to be a picture of himself with a laryngeal reflector on his forehead. Surely such apparatus is superfluous for a man who has the power of discovering what there is in a man's throat without seeing the patient.

DISSEMINATION AND LOCALIZATION OF ANTIMONY IN ANIMALS—OZENA AND METHYLENE BLUE—PENETRATING WOUND OF THE SPINAL CANAL—PENETRATING WOUND OF THE SPINAL MENINGES WITH ESCAPE OF CEREBROSPINAL FLUID—GUNSHOT FRACTURE OF THE SKULL.

M. G. Pouchet, at the Académie de Médecine, Oct. 1, 1901, read a paper on the dissemination and localization of antimony in the system of animals, especially of rabbits and dogs, with the view of indicating the sites of its deposit and spread in man. His first animal was a rabbit and weighed 1095 grams; it absorbed 30 doses of tartar emetic each 0.005 grams, representing 0.054 grams of antimony. It was then killed. A search for the poison was almost negative except along the digestive tract; the skin and the fur gave only the slightest possible reaction. This experiment lasted fifty days. Three other animals, weighing respectively 2,000, 1,960 and 1,890 grams, were fed the drug for 115 days, absorbing in that time 1.314 grams of the metal. At first the animals increased in weight and otherwise improved, but during the last of this period lost their fur, which had up to the alopecia become more lustrous, and their skin also became scaly and peeled off, leaving red excoriated areas. At the autopsy all the organs appeared practically normal, except those of the gastro-enteric system, where alone the drug was distinctly found. The brain was absolutely negative; the skin, nails, hair, liver, spleen, bones, kidneys, muscles, etc., were all virtually without reaction or at most with a slight reaction. Dogs gave the same manifestations. The addition of even a little arsenic hastened the clinical conditions, especially those of the nervous system, and the findings at the autopsy were considerably altered. The cerebrospinal axis, muscles, liver, etc., contained arsenic, but no antimony. The bones contained each in traces. The skin and hair also showed both, with considerable increase in antimony. The digestive tract had much more antimony and considerable arsenic. The administration of other drugs of the class of bromide of potash appeared to have much influence in the symptomatology and in the distribution and quantity of the findings.

Hallopeau, at the next meeting, Oct. 8, 1901, gave a few notes suggested by the work of Bounet (Massiac) on the treatment of ozena with methylene blue. A two-and-a-half-per-cent. solution is used as an irrigation, at first thrice, finally once daily, always with most favorable results within about three or four weeks. It has the unfortunate disadvantage of staining the lips and nares. In syphilitic ozena it appears to limit only the secondary infection, having no influence upon the syphilis.

Loison, military surgeon, at the Société de

Chirurgie, Oct. 2, 1901, narrated the facts of a case of a small caliber projectile, movable within the spinal canal. The soldier was shot in the back, in the lumbar region, with a Flobert rifle. Radioscopy gave no tangible results. Physical examination revealed only the wound of entrance. Radiography disclosed the ball in the sacral region about two centimeters from the surface. Judging from the external wound, the ball probably entered between the second and third lumbar vertebræ and then once within the canal fell by its own weight as far as the cul-de-sac of the arachnoid would permit. Upon the cadaver, he proved that such a condition could easily exist. Trepanation and exploration failed to find the ball. A second radiographic picture showed its movability. Then the method of Contremoulin served to locate and extract it.

MATHIEU (army surgeon) in behalf of M. L. Giss (Thionville) reported a case of penetrating stab-wound of the neck at the level of the sixth vertebra. About twenty-four hours after the injury a serous fluid began to issue from the wound and the patient showed paresis of the right upper extremity. As the point of the knife remained in the wound he diagnosed its entrance through the meninges. After some difficulty this fragment was removed and the cerebrospinal fluid continued to ooze at the rate of four or five liters a day on some occasions. The outflow suddenly stopped itself. The total loss appears to have been about thirty liters. A long slow recovery followed. The recovery has persisted for two years up to the present.

PICQUÉ also reported a gunshot case for Toubert (military surgeon) involving the right temporal region in a large fracture. Primary trepanation could do little. Tamponade of the wound was necessary. At the autopsy, three days later, it was found that the ball had lodged in the left optic tract posteriorly, after having damaged the right also. During life glycosuria and albuminuria appeared after the injury—perhaps because the ball damaged or passed near the floor of the fourth ventricle.

SOCIETY PROCEEDINGS.

HARVARD MEDICAL SOCIETY OF NEW YORK CITY.

Stated Meeting, Held Saturday, October 26, 1901.

The President, Howard Lilienthal, M.D., in the Chair.

Functional Derangements of Thyroid Gland.—The paper of the evening was read by Dr. John G. Perry and detailed a series of cases in which functional disturbance of the thyroid secretion seemed to be the basis of a distinct pathological condition. Dr. Perry said it is now well recognized that myxedema is the result of the entire absence of the thyroid gland. With the question of symptomatic affections due to lessened function of the thyroid, however, there is much uncertainty. He has found in the experience of the last few years, a series of cases in which especially the therapeutic test of relief after the administration of thyroid extract has forced him to the conclusion that functional disturbances of the thyroid are not infrequently the basis of obscure symptoms usually attributed to other causes.

Symptomatic Picture.—The symptoms presented by the patient who derives benefit from the thyroid treatment under Dr. Perry's care presented a decided uniformity. Five symptoms were usually present. The most noticeable of these was pain in the joints. The other symptoms were a feeble and rapid heart, a tendency to headache, not localized but general; in women, menorrhagia and the usual development of the symptom-complex after a shock or fright. Because of the presence of the pain in the joints, nearly all the cases had been treated for rheumatism. In some of them, after the failure of rheumatic treatment, physicians had come to the conclusion that suppressed gout existed, and treatment for this condition had been applied. The joints were not red and usually were not very tender. There was frequently a pallid swelling with slight tenderness, resembling the conditions which develop in the so-called neural arthropathy described by Charcot. One of Dr. Perry's typical patients was an unmarried woman who was thought to be suffering from suppressed gout. She had not been benefited by any therapeutic measure employed. She was gradually drifting into a helpless condition of invalidism. In addition to a peculiar pallor of the face, the eyes were drawn together, and the pinched expression, with compressed lips, indicated an intensely neurotic condition. This was noticeable particularly during her painful attacks. The attacks were not associated with flatulency nor gastric disturbance and did not simulate migraine. The day after an attack she would be up, feeling reasonably well, but without appetite and physically depressed.

Local Symptoms.—Her so-called attacks of gout were localized in the knee. This was not swollen nor reddened, but was puffy and tender. In women increase of menstruation was a marked feature and in this case this symptom evidently rendered the condition more serious. Examination disclosed the presence of a flabby uterus presenting much less resistance to the examining finger than usual. Derangements of the gastric function were common, but seemed to have no necessary connection with the attacks. The urine was negative and, though special attention was given this point, no urates nor uric acid in excess were found to be present. In a word, the only reason for the diagnosis of suppressed gout were the uncomfortable feeling in the joints and the culmination of this feeling at stated intervals.

Presumed Etiology.—When the patient herself was asked to state what she thought to be the cause of her condition she attributed it to a railroad accident, in which for a time she had become separated from a very dear friend, and had concluded that that friend was beneath the

wreck. Inquiry among friends elicited the fact that the railroad wreck had been a very serious one and that the condition of mind that developed in the patient as a consequence of the supposed loss of her friend after going through a period of serious personal danger had been amply sufficient to produce an intense emotional strain.

Psychical Symptoms.—Some of the most important symptoms in this case were mental. The patient had never been considered eccentric. Since the accident, however, she had become abrupt and forbidding in her manner, and, though more or less unconsciously to herself, not infrequently insulted old and dear friends. After talking quietly with a friend for some time, she was apt to interrupt the conversation and take her departure from the room or the house, and, from being a rather sensible person, had become extremely sensitive.

Treatment.—The only physical sign in the case that seemed to provide a possible rational indication for treatment was the filling in of the suprasternal notch. With the idea that the thyroid gland or some disturbance of its function might have to do with the symptoms, psychical as well as physical, extract of thyroid was given for some time. At first, one five-grain tablet of thyroid extract was given every day. Two tablets for some days and, as there was not any nausea nor heart disturbance, the dose was increased to three, and was continued for some months. After the first month there was a notable decrease in the symptoms. After a year of treatment the patient was advised to take only two tablets a day, but to resume the taking of more of the extract, even to four tablets a day, if any of the old symptoms recurred. She has had no attacks now for several years.

Theory of Etiology.—As the result of the therapeutic test, the only consistent theory of the etiology of the symptoms was that the shock to the nervous system had caused a diminution of the function of the thyroid gland. As soon as sufficient thyroid extract was supplied the patient improved and this improvement has continued. There remains, of course, the important question as to how long the patient shall have to continue the use of thyroid extract. There is every reason to hope that the improvement of the general condition consequent upon the taking of thyroid extract will foster also the nutrition of the thyroid gland and bring it once more to perform its function as completely as before. In the meantime, the continued relief of symptoms leaves no room for hesitation that the thyroid extract has been effective as a therapeutic measure.

A Second Typical Case.—This patient was the daughter of an old army friend. She was sent from a distant city in the fourth month of her pregnancy. She was in an intensely neurotic condition. The headache, the tender joints, the liability to exacerbations and the feeble, rapid heart, with obliteration of the suprasternal notch were distinctly present. There was no menorrhagia, but this had existed before her conception. She was put at once on five-grain tablets of thyroid extract. The case proved, however, extremely obstinate to thyroid medication. No improvement was noticed for two months. Then she began to gain in weight and her other symptoms rapidly improved.

Appearance of Child.—The delivery was normal, although there was some terminal uterine inertia that required assistance. The appearance of the baby was, as the grandparents described, humorous, to say the least. The nurse called attention, when the baby was about a week old, to a constant habit of rotation of the head, which the baby exhibited. Examination showed that there was some opisthotonus. The face, while full and well nourished, was pale and somewhat pasty. There was a fulness about the lips and under the eyes that gave a peculiar expression. The baby was given thyroid extract at first in doses of two grains each day; later two grains three times a day were given. Very shortly the appearance of the face began to change and the countenance became more human. This improvement continued until an apparently normal condition was reached and this has persisted for two years. The child's teeth came late, but at the present time it has the full complement for its age and enjoys perfectly good health. The only question is, shall the administration of thyroid be stopped or shall it be continued?

The Third Generation.—The child's grandmother has suffered for a long time from a chronic ailment with subacute exacerbations that had made her a confirmed, though rather a resigned invalid. She had an especially weak heart and her physician was often compelled to spend the night by her bedside in hourly expectation of death from heart failure. She believed herself an enigma, but considered that a fatal termination of her ailment by heart failure was inevitable sooner or later. She came on to New York to see her daughter and grandchild and so came under Dr. Perry's care. The grandmother's condition was very similar to that of her daughter. Her heart was very feeble and the circulation so poor that sensitiveness of the joint structures might have been expected. She was so weak that she was practically bedridden and had resigned herself to this state of affairs. She was put on thyroid extract and after a few weeks began to improve. She has a decided disinclination for the drug and feels that it produces a sort of intoxication in her after some time, but she continues to use it intermittently because of the good she feels it does her. In this case, after about three weeks' administration of the drug, symptoms of intolerance developed. These were more subjective than objective. There was a feeling of gastric uneasiness and cardiac discomfort. A sense of repletion that somewhat interfered with the appetite also developed and produced the impression that something was being taken that intoxicates. After an interval, however, of absence of the drug these symptoms disappeared. With regard to the child, if it had been

healthy, the drugh would not have been administered. On the other hand, a normal child would surely not have tolerated the large doses of the drug, two grains three times a day, that were administered during the first two years of life.

Significance of the Condition and of the Medication.—Dr. Perry thought that these cases represent a hitherto undescribed symptom-complex, and that the use of thyroid is indicated only on empirical grounds. His success in the use of thyroid extract justifies him, however, in believing his diagnosis correct and seems to open up a new chapter in successful therapeutics. The subject is as yet only on trial, but what has been found is suggestive and indicative of important functional disturbances of ductless glands that have thus far not been suspected.

Thyroid Extract in Otology.—Dr. Joseph Kenefick said that in looking over a recent review of therapeutics in otology, he had noted that certain authorities recommended thyroid extract in otitis media and claimed to have obtained good results from its use. It is well known that otitis media has a special tendency to develop in persons suffering from the gouty diathesis. It is not improbable, then, that there are certain cases in which the affection occurs as the result of what might be called the thyroid diathesis, a diminution of the function of the thyroid gland.

Functional Thyroid Disturbance.—Dr. Edward M. Foote said that surgeons have reported cases in which the removal of a large portion of the thyroid has been followed not by complete, but by partial myxedema. It seems perfectly easy to conclude, therefore, that a disturbance of the function of the thyroid which limited its secretion to a considerable extent, might act in the same way as a removal of a large portion of the gland. Surgeons have found that the modified myxedema, incident to partial removal of the thyroid, can be rendered innocuous by the administration of thyroid extract. This would furnish at least a theoretical basis for the administration of the thyroid in the cases of diminution of function of the thyroid.

Action of Thyroid Extract.—Dr. Charles Schram said that there is as yet no absolutely sure scientific basis for the thyroid treatment. While it has been administered in a number of cases with reported good results, its administration has not met with general satisfaction. Dr. Schram has used it particularly in cases of obesity and, like most others, he found that it did help in the reduction of the weight, but as soon as the administration of the drug is stopped the patients rapidly regain their weight. Exercise accomplishes the same beneficial purpose of reducing the weight and provides the patients at the same time with habits of life that enable him, or her, to keep the weight from rising too high again.

Iodothyrin.—Dr. J. Hilton Waterman said that in cases of obesity in which thyroid extract is used it is not uncommonly found that irregularity of the heart action develops. When there is much fatty infiltration this cardiac irregularity is so marked as to constitute an absolute contraindication to the use of the drug. Iodothyrin, one of the supposed active principles of the thyroid gland, is much better borne, as a rule, than the crude extract, but its results in the reduction of the weight are not so marked. As a rule the use of thyroid in any form for obesity is satisfactory only for the time being.

Thyroidism.—Dr. Howard Lilienthal said that the study of the ductless glands is undoubtedly the most important subject of the new century. Thus far pathological conditions alone have been considered. It is possible, however, that there may also be functional disturbances. In the cases described, however, there is a question whether there may not have been a failure of the gland to develop to its normal extent and consequent lack of function with a condition of unstable equilibrium of nutrition. With regard to the symptoms of thyroidism and of intolerance of the remedy, Dr. Lilienthal noted in one case in which he employed it the occurrence of glycosuria. This symptom was not present when the drug was first administered, but developed during its administration and persisted afterward to some degree.

Supposed Chlorotic Conditions.—Dr. Perry in closing the discussion said that the cases which he has noted resemble chlorosis not a little, especially when they occur in young women. It is well, then, for the practitioner when anemia is present to note the condition of the suprasternal space and, if it is not depressed, to bear in mind the possibility of thyroid being useful in the treatment of the case. It is wonderful how much objection there seems to exist in the minds of physicians to the administration of thyroid. More than once when his patients have gone to a distance, Dr. Perry has asked them to go to their physician and have him prescribe for them thyroid extract, as it had been used before. Almost as a rule, physicians refused after a certain time to take the responsibility of further continuance of the remedy. The most remarkable thing in Dr. Perry's series of cases was the absolute tolerance for the thyroid extract shown by the patients.

Graduated Dosage.—Dr. Perry said that all patients are not able to stand the dosage suggested in the two cases described. In a recent case a young woman came to him in an excited condition with a feeble pulse over 100. She was told to take two five-grain tablets of thyroid extract per day. Within a week she came back so agitated as to be scarcely able to speak. Her pulse though weak was running furiously. The thyroid extract was stopped and when its effect had passed off, she was directed to take half a tablet twice a day, but with the same result. The doses were made smaller and smaller until, finally, only $^1/_{13}$ of a tablet was given twice a day. She gradually became accustomed to this and the dose was increased to two tablets a day. This patient was intensely sensitive to the action of thyroid extract, but the cure of her condition was rapid.

Thyroid Extract as a Heart Tonic.—Dr. Perry says that for cases of feeble heart there is no heart tonic that is so effective as thyroid extract. After digitalis, strophanthus and other recognized heart tonics and stimulants have been used without success, Dr. Perry has employed thyroid extract and found it to do good. In cases of weak heart action without definite valvular lesion he now uses it regularly in preference to other heart tonics and invariably gets good results. In the weak heart that often occurs with obesity he had found thyroid extract especially useful. It controls the tendency to rapidity of heart action after exertion and adds greatly to the comfort of the patient. With regard to the use of the thyroid extract in obesity a certain selection of cases for the treatment should be made. Many cases of obesity are accompanied by anemia, general systemic feebleness and a weak heart. These cases invariably do well on thyroid extract.

SOCIETY OF DERMATOLOGY AND GENITO-URINARY SURGERY.

Stated Meeting, Held October 11, 1901.

Case of Keloid.—Dr. F. Cabot presented the case of F. V., colored, aged twenty-seven years, male, native of Cuba, cigarmaker, who noticed in 1894 for the first time a lesion on the right cheek, which he describes as smooth and hard, of the size of a bean, painless and slightly elevated. This lesion was cut out by a Cuban surgeon in 1896, but soon returned, and is now the size of thumb. Quite a number of other lesions of similar nature are now found on the chest and various parts of the trunk. There is no history of local injury, except perhaps friction in connection with the lesion on the right elbow. No evidences of syphilis, past or present, are present.

In discussion Dr. Leviseur said that the colored race is particularly prone to the development of true keloid. Some authors claim that the differential diagnosis made by the microscope shows that in true keloid the papillæ of the skin are preserved, while in spurious keloid or in a hypertrophied scar they are absent. As far as treatment is concerned the injection of thiosinamine has been recommended. He had not had any success with electrolysis, although he had tried it in a number of cases. Excision is risky, because as a rule the tumor reappears. At one time continuous pressure by aid of bandages, or a pelotte, was recommended by French authors. This method of treatment was given a trial in two cases without success. The keloid developing in or around a syphilitic scar promptly disappears under energetic antispecific treatment.

Dr. Lapowski said that good results have been obtained from the use of thiosinamine. It might be injected directly into the keloidal tissue. Regarding syphilitic keloid, he had treated a case in which the injection of calomel and large doses of potassium iodide had little or no effect.

Dr. McGowan said that it is evident that if thiosinamine is injected directly into the keloidal tissue much more rapid results are produced than if the injection is made under the healthy skin for its general effect. He had not seen any great benefit from it.

Dr. Whitehouse had not obtained good results with thiosinamine, but had successfully employed 10 per cent. oleate of mercury and mercurial plaster. Occurring in the white race the various remedies and methods of treatment are worth a trial; but if in the negro it is preferable to leave the affection alone.

Dr. Lusk had tried thiosinamine in 11 cases, internally and hypodermatically, between the shoulders, around and in the keloid. At first there was apparent improvement in some cases, but after two to six months' treatment he failed to find any good results from its use. He succeeded in relieving the irritability by protecting the parts from pressure and applying a coating of collodion containing 10 to 15 per cent. of belladonna.

Case for Diagnosis.—Dr. Green presented this case. The patient was seen about two months ago, when her husband asked him to examine her. At first a diagnosis of eczema was made and a zinc and camphor ointment was given to relieve the itching. The eruption became worse. Changing the diagnosis later to psoriasis, arsenic and an ointment consisting of Lasar's paste with oil of birch tar, one dram to the ounce, was prescribed. She still became worse. Then iodide of potash was given, after which the patient began to improve. A salve of white precipitate ointment was also given. The improvement continued, and the spots almost entirely disappeared. The patient disappeared from observation for four weeks, after which time she presented herself with the eruption as seen at present. The case was puzzling, because it certainly had the features of eczema, psoriasis and syphilis, but did not improve with treatment for eczema or psoriasis, but yielded to antisyphilitic remedies.

Dr. Leviseur considered the case one of seborrheic eczema. Dr. Lapowski considered it syphilis combined with seborrheic eczema, the syphilis predominating. Dr. McGowan was inclined to regard the case as psoriasis, as the brawny, dry, scaly appearance that is found in seborrheic eczema does not seem to be present. The flexor and extensor surfaces are involved, and psoriasis does not limit itself exclusively to the extensor surfaces. It has been in existence off and on for twenty years. He advised a course of arsenic and local application of salves ordinarily used in psoriasis. Mercury is beneficial in psoriasis, but he was confident the psoriatic treatment would accomplish as much as the antisyphilitic.

Dr. Lusk said that he had had a number of cases similar to this, chronic psoriasis appearing more or less continuous for a number of years, and upon that a papular syphilide. Dr. Whitehouse thought it a difficult matter to give a defi-

nite opinion in regard to the case without a careful examination by daylight. He believed the patient to be syphilitic, but at the same time could not conceive of a syphilitic eruption coming and going and being present for twenty years. There is some other eruption subjoined.

Case of Lupus Vulgaris Exuberans.—Dr. Leviseur presented the case of a girl, twenty-four years of age, who consulted him last winter in regard to an ulcerating lupus vulgaris of the entire nose and neighboring parts of both cheeks of eight years' standing. She had been treated by the ordinary methods in several dispensaries and hospitals. The affection had destroyed both alæ nasi, and there were deep ulcerations partly covered by thick brown crusts partly exposed and discharging freely. The whole nose was mushy, and ready to break down at any moment. After constructing a Finsen apparatus with lenses which he had brought from abroad, he began treatment, using a self-focusing stereopticon lamp of 2,000 candle-power and 15 amperes. The patient had 45 sittings of an hour each, at first every day, and then at intervals of one, two, and finally three days. No improvement was noticed until two weeks after the last sitting when the ulcerations began to heal and the skin began to become hard. Since treatment with the Finsen light during the summer is very inconvenient (the sunlight in the open air is generally used abroad) he destroyed some of the remaining lupus nodules by aid of electrolysis. The result, particularly from a cosmetic standpoint, was certainly remarkable, even if the affection should recur later on. It equals the success of the cases which he had seen in Paris the summer before last. They were sent over from Copenhagen and put side by side with lupus cases treated by excision, transplantation, cauterization, scraping, etc., demonstrating the superiority of the new treatment.

Dr. McGowan said that Dr. Pusey of Chicago has reported very excellent work in the treatment of lupus with the X-ray. The speaker had tried the X-ray in cases of carcinoma referred to him with good results. Dr. Leviseur said that the action of the X-ray and the Finsen light is very similar. The danger of producing a dermatitis or sloughing with the X-ray must always be considered. Dr. McGowan said that since low-pressure tubes were obtainable there is less danger from gangrene. There is no doubt but that the results from the X-ray or Finsen light are far superior to anything preceding. Dr. A. B. Johnson said that the previous speaker had stated that it has been found that high-pressure tubes are more apt to produce X-ray burns than tubes of low pressure. If by that is meant that high-vacuum tubes are more likely to produce burns than are low-vacuum tubes, he believes him to be mistaken, for the contrary is the fact in his experience. It is impossible to explain why this should be so, yet such is the experience of those whose opportunities have been greatest in this field. His own experience in the detection of calculi in the kidney, where a tube of low vacuum must be used in order to get the best results, indicates that exposures with such a tube not more than one foot from the skin will produce dermatitis in a small proportion of cases, provided the aggregate time of exposure is fifteen minutes or more at any one sitting. Such dermatitis may be avoided by placing the tube not nearer than eighteen inches from the skin, limiting the time of exposure to ten minutes, or less, and refraining from a second exposure for from ten days to two weeks. The utility of protective measures, such as cleaning the skin, greasing the skin, or the use of a grounded, thin metal screen between the tube and the body of the patient, is doubtful. While with good apparatus it is not hard to show the presence of a stone of considerable size in the kidney of a thin individual, in the case of large, stout persons the difficulties are much greater. It is not sufficient to be able to show the presence of a stone of considerable size; we desire, also, to be able to establish a negative diagnosis. It is desirable that the stomach and large intestine be empty at the time the exposure is made. Experience in the examination of X-ray negatives of the kidney region is necessary to enable one to say whether a given picture shows sufficient detail to establish a negative diagnosis.

BOOK REVIEWS.

The Diagnostics of Internal Medicine. By Glentworth Reeve Butler, A.M., M.D., Attending Physician to the Methodist-Episcopal Hospital (Seney), Brooklyn. D. Appleton & Co., New York.

Heretofore the works of Vierordt and Musser have reigned supreme in the field of internal diagnosis, and excellent books they both are. A new claimant for honors is here presented in this book of Dr. Butler's and it may be at once conceded that it has at the first leap put itself on a par with the best of American text-books—Musser—if it does not surpass it.

Coming as it does from a heretofore little-known author, this is all the more surprising, but it is just such kind of surprises that bring anew into prominence the truth that the masters of medical science are not those who are continuously blowing their horns, in season and out of season, but that many a quiet worker is busily gathering excellent material and arranging it for his fellow workers.

The work before us varies in some respects from others of its kind. We do not know of any recent work on diagnostics which deals so exhaustively and at the same time so practically with the science and art of the examination of the patient. Its thoroughness and lucidity are striking attributes and the student of medicine of today is to be congratulated that he here has a work of such finish to aid him in the gaining of the character of the diseased process under consideration.

Another feature, which is perhaps not as desirable, and yet is a necessary part of a work of this kind, is the condensed series of descriptions of diseased processes. Had not this condensation been done in the able manner in which it has, this portion would partake of the character of many manuals of medicine, but in its present concise and yet comprehensive form this criticism does not avail and the author shows evidence of rare discrimination in the use of striking symptoms in description. Etiology, symptoms and differential diagnosis are alone considered. Therapy is not mentioned.

A review of this work would not be complete without a word as to several chapters which have been contributed by other workers. These are excellent aids to the book and supplement in a masterly manner the central body of the text. Chapters by Drs. Shaw, Webster, DeForest and others are excellent. That on nervous diseases by Drs. Jelliffe and Bonar is sufficient and yet comprehensive, the authors' central idea of the inclusion of all necessary details being well carried out.

The illustrative features constitute a veritable *tour de force,* they are nearly all derived from photographs and the author and publisher are to be congratulated on their recognition of the value of good illustrations, even though they may be found somewhat striking to the general onlooker. The publisher's part in the work is on the same high level that has always been the pride of this old New York house. We predict for Dr. Butler's work a great success and a well-deserved one.

STRENGTH FROM EATING. HOW AND WHAT TO EAT AND DRINK TO DEVELOP THE HIGHEST DEGREE OF HEALTH AND STRENGTH. By BERNARR MACFADDEN. Physical Culture Publishing Company. New York.

IT IS not often that an anomaly of this type strays into the reviewer's hands and when it does, were it not for calm effrontery of its supreme ignorance of matters hygienic and sensible, the reviewer would pass it by with a smile.

If there is a type of "yellow journal" hygienic science, such a work typifies it. Sensationalism and fulsome hyperbole are its main attributes and were it not for a vein of sense discernible here and there, even the uneducated reader, for whom the book is specially prepared, would not take the trouble to read it.

If a little knowledge is a dangerous thing, one wonders how dangerous is none at all. If the dear, discriminating public are told that "even soups must be submitted to a certain amount of *chewing* in order to mingle it with saliva" one wonders what rare and wonderful physiological processes are necessary to get the air in the lungs.

This work taken as a whole is very amusing. It should be read by a medically trained man to appreciate what the public is taught regarding the processes of digestion by such manuals. He will no longer wonder why Sixteenth Century ideas are still in the minds of the people.

TRAITÉ DE MÉDECINE ET DE THÉRAPEUTIQUE. Publie sous la Direction de MM. P. BROUARDEL et A. GILBERT; Tome Huitième. Maladies de Pleures et du Mediastin, Maladies de l'Axe Cerébro-spinal. Par MM. LANDOUZY, M. LABBÉ, GALLIARD, MENETRIER, BOINET, ACHARD, BALLET, P. MARIE, LÉVI, KLIPPEL. J. B. Baillière et Fils, Paris, France.

THE eighth volume of this masterly treatise, treating of diseases of the pleura, the mediastinum and the cerebro-spinal axis, comes as a welcome addition to those that have gone before. The discussion of the diseases of the respiratory tract is here completed and that of the nervous system begun.

There is little that is new in the author's treatment of pleural conditions; the subject of the cyto-diagnosis of pleural exudates is perhaps an exception to this treatment, but in the chapter on mediastinal diseases there are a number of interesting observations by Boinet.

The opening chapters on nervous diseases promise much. The subject of aphasia is taken up by Ballet; P. Marie discusses hemiplegia and paraplegia and Achard, apoplexy and coma, delirium, convulsions contractures, tremor, vertigo, headaches, and tropho- and vaso-neuroses. Cerebral pathology is treated by P. Marie and M. Klippel. Thus many of the foremost neurologists of France are engaged in this volume and their work justifies their reputation.

BOOKS RECEIVED.

The MEDICAL NEWS *acknowledges the receipt of the following new publications. Reviews of those possessing special interest for the readers of the* MEDICAL NEWS *will shortly appear.*

A CIVILIAN WAR HOSPITAL. Being an Account of the Work of the Portland Hospital, and of Experience of Wounds and Sickness in South Africa, 1900. By the Professional Staff. 8vo, 341 pages. Illustrated. Longmans, Green & Co., New York.

DISEASES OF THE UPPER RESPIRATORY TRACT, the Nose, Pharynx and Larynx. By Dr. P. Watson Williams. Fourth Edition. 8vo, 436 pages. Illustrated. Longmans, Green & Co., New York.

ORIGINAL ARTICLES.

TRAUMATIC STRICTURE OF THE ESOPHAGUS.

BY F. E. BUNTS, M.D.,

OF CLEVELAND, OHIO;

PROFESSOR OF PRINCIPLES OF SURGERY AND CLINICAL SURGERY, MEDICAL DEPARTMENT, WESTERN RESERVE UNIVERSITY.

SINCE the introduction of retrograde dilatation of the esophagus by Lonta[1] and Von Bergmann in 1883, it would seem that the ingenuity of our surgeons has been directed toward improvements and modifications of this radical procedure, and that having discovered that the operation was a feasible one, although not unattended by danger to life and sometimes followed by the maintenance of permanent gastric fistulæ, as in two out of twenty-one cases collected and reported by Franks,[2] they seem somewhat disinclined to return to the more tedious, though safer method of gradual dilatation.

F. Erlich[3] reports a case of esophageal stricture, following scarlet fever in a child five years old, in which unsuccessful attempts at retrograde dilatation, after the performance of gastrostomy, were followed by successful dilatation by means of spiral bougies and laminaria tents and graded bougies. H. Zeehnisen[4] reports two cases of stricture of the esophagus caused by swallowing lye. He followed König's method, using silver balls attached to strings. The patient would swallow the ball at night as far as it would go. In the morning the ball would be found in the stomach and pulled out. Each night a larger ball was used, until finally a large-sized tube could be passed into the stomach. E. Summa[5] reports a case of stenosis of the esophagus in which a child, two years old, drank lye, and when fourteen years old had great difficulty in swallowing. Some relief was obtained on dilatation. When sixteen years of age patient had pain in the epigastrium and coffee-ground vomiting occurred. Gastro-enterostomy was performed and the patient died. There was a circular scar an inch below the pharynx and a second stricture which extended from the trachea to the cardia. There were also an old gastric ulcer and an ulcer of the duodenum. The author considers the ulcers due to the ingestion of the lye.

The treatment of esophageal strictures by electrolysis is sometimes successful and one case of forty years' standing is reported by W. S. Watson[6] as having been cured. The uncertainties of this method, together with the dangers attending its employment, will probably prevent its ever being generally adopted.

F. W. Samuel[7] says that the treatment by mechanical dilatation is applicable only to such cases as can easily swallow semi-solid food. This imposes upon the patient an almost lifelong task, and he thinks that gastrostomy with retrograde dilatation by the Kraske or Abbe method is the best treatment known at the present time. That this statement is entirely too sweeping, I believe a reference to the cases which I have to report will show, and, if mechanical dilatation be applicable only to those cases in which semi-solid food can be swallowed, it is because suitable bougies have not been obtainable.

Stricture of the esophagus is one of the most frequent pathological lesions of this organ. Inasmuch as the tendency of such a stricture, if left alone, is to contract progressively, just as we find in strictures elsewhere, a method for its relief becomes a most important problem for the surgeon to solve. The comfort and welfare, even the life of the patient, depend upon the recognition of the lesion and its proper treatment.

The congenital form of stricture is comparatively rare, and while in its simplest form it is amenable to treatment by dilatation, yet in that form in which the tube is completely occluded there is practically no cure, notwithstanding the various ingenious operations which have thus far been resorted to. Spasmodic stricture is essentially of nervous origin and is most common in women; its true character is easily made out, if necessary, by an examination under an anesthetic. Those strictures resulting from the presence of cancerous, tuberculous, or syphilitic growths or from pressure of tumors and other pathological conditions outside the esophagus must be diagnosed by inspection, microscopic examination, bougies and by the history of the case. Their final treatment is nearly always operative.

I wish to speak only of traumatic cicatricial strictures. These strictures are caused by wounds of various kinds and more frequently by the swallowing of strong acids or alkalies. The pain caused by the caustic swallowed may at first be sufficient, when coupled with the lesion which it would naturally cause, to account for the temporary dysphagia. But later, when the pain has disappeared and yet the inability to swallow solid foods continues, the true nature of the trouble may possibly suggest itself to the patient or his friends. In those cases which have been neglected the progress is usually very rapid, especially in the severer forms. The inability to swallow solid food is soon followed by an equal inability to swallow the softer foods, such as gruels, and in a short time even water and milk will, with the greatest difficulty, find their way through the tightening grasp of the cicatrix. Up to this time the patient has managed by repeated and deliberate efforts at swallowing food and drinks to keep up a fair degree of nourishment, and may have been able even to attend to his ordinary occupation. Naturally, as his power to swallow even fluids becomes more

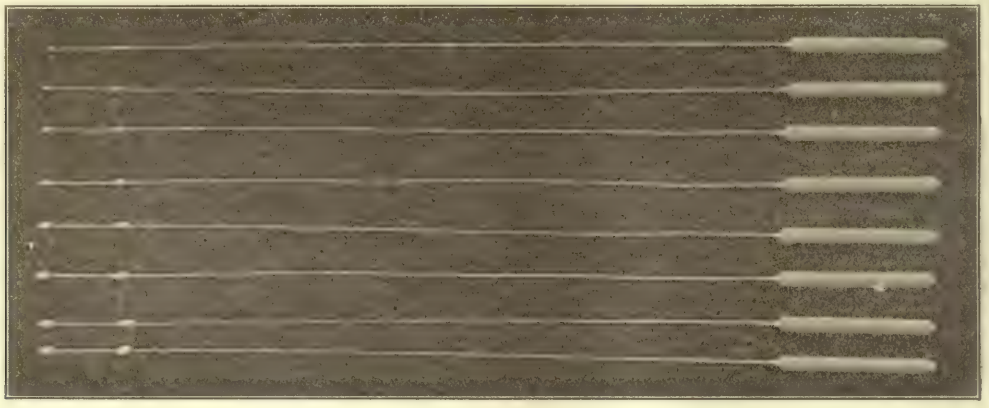
and more diminished, his strength gradually fails, regurgitation of everything swallowed occurs, and the picture is soon that of one who is dying of starvation and thirst. Emaciation is rapidly progressive and unless surgical aid is obtained death soon ensues from exhaustion.

The diagnosis of these cases rests first with the history. Ordinarily this is easily obtained, but when the patient is a small child it is frequently difficult to find out just what has been swallowed. Almost every household uses lye for cleaning out sinks and drains and a small amount of it left in a cup may be swallowed by mistake. Next must be taken into consideration the symptoms: deglutition becomes progressively impaired until all or part of the food is vomited, and this persistent inability to swallow or retain food of any kind should call attention at once to the possibility of a stricture. At first the food in the early stages of obstruction comes up undecomposed; later, as the esophagus becomes more tolerant, the food may be retained until decomposition takes place.

Those strictures resulting from ulcerative processes are liable to be found in the lower third of the esophagus quite as frequently or even more frequently than in the upper third, while those due to mechanical injury, the most frequent of which is the swallowing of lye, are most liable to be found in the upper third, though such a large quantity may be swallowed as to allow enough to trickle farther down and attack almost any part of the tube. The convincing test is, of course, the esophageal bougie, and if the other form of stricture can be excluded and the bougie meets with obstruction in any part of its course, a cicatricial stricture may be safely diagnosed.

The prognosis depends upon the extent of injury to the mucous membrane and consequently the degree of rapidity of contraction. The rapidly contracting strictures are the ones most difficult to dilate and keep dilated. The degree of stricture which permits the taking of liquids and semi-solid foods is perfectly compatible with life and active business pursuits, and may never call for interference on the part of the surgeon, but the greatest number of cases pursue a most unfavorable course and terminate in death if not speedily relieved.

I have now treated eight patients with stricture of the esophagus, each of which was caused by the accidental swallowing of lye. Some of these patients have been children, some adults. In all the stricture was a very small one, and in most the passage of even a filiform bougie was accomplished after several days of repeated effort. I found it impossible to get esophageal bougies small enough for the class of strictures I encountered, and, therefore, I have had made a series of graded double-bulbed olive-shaped bougies which are here illustrated and which have given me much satisfaction. It will be observed that on each staff there are two bulbs, the first being one size of the French scale smaller than the second bulb. This serves to permit one to follow up the advantage gained by passing one bulb, by the immediate passage of one a size larger. Sometimes it will be impossible to increase these sizes more rapidly than one or two of the French scale in every three or four days, at other times we may succeed in dilating it several times each day. Much depends upon the degree of stricture and the depth of the original injury.



Esophageal Bougies.

Great gentleness and care are required, and, if one meets with repeated lack of success in one day, it is better to allow the patient to rest for a day or two, if his state permits it, and then try again. In children I have found it necessary to use a mouth gag; in adults this has not been necessary. On inserting the bougie it is best to have the patient sit upright, in a straight-backed chair, the head thrown back somewhat, in order to straighten the line of introduction of the bougie. Instead of passing it directly back in the median line, it is probably better to pass it into the pyriform sinus at the side of the larynx, which affords a funnel-like aperture that will allow the bougie to slide into the esophagus without encountering the bodies of the cervical vertebræ or the cricoid cartilage. Force should never be exerted.

I have not spoken of retrograde dilatation, nor of gastrostomy, nor gastrotomy, in the treat-

ment of these cicatricial strictures, because in my experience it has never been necessary to resort to such measures, and while dilatation is always more readily accomplished in recent strictures, yet, even in one which had existed for seventeen years, during which time the patient was obliged to live on liquid diet with a stricture measuring from 4 to 6 of the French scale, and who had lost all of his teeth by reason, I presume, of improper nutrition and of never having chewed solid food, I was able by persistent and painstaking dilatation to stretch the stricture to a size sufficient to permit him to swallow solid food when reasonably well masticated.

I wish briefly to relate the history of the cases which have come under my care:

Case I.—A child two years old had been at the "Fresh Air Camp" for malnutrition and persistent vomiting. When brought to the dispensary it was greatly emaciated, fretful and anxious-looking. The mother said it had not been able to retain anything for two or three days, even a teaspoonful of water being regurgitated in a few moments. I tested the child myself and found the statement to be true; it was constantly crying for water, but could not retain the slightest amount. Suspecting a stricture and finding upon questioning the mother that the child had swallowed lye, although a very small amount, as she declared, I endeavored to pass a bougie, but, meeting with an obstruction, was compelled to use a smaller one, a No. 8, French scale. Immediately after passing the bougie I handed the child a glass of water, and before we could get it away it had ravenously swallowed the entire contents of the glass and showed no inclination whatever to vomit. The child was brought for treatment at irregular intervals for a number of months. The progress was, however, very unsatisfactory, inasmuch as the mother would not bring it back except as the stenosis became too great for it to swallow water. At first the child regained its flesh and strength with surprising rapidity, but later, as the treatment became more and more irregular, it began to decline and the stricture became more and more difficult to overcome. The last time I saw it I was unable to insert a No. 8 bougie, and its condition was such that I could hardly expect it to live longer.

Case II.—This case was referred to me by Dr. Ashmun, who saw the patient some time after the accident. When first seen by me he was in the hospital, where he had gone for an operation. He was greatly emaciated, very weak, scarcely able to stand, and unable to swallow even water, so that we were obliged to give him nourishment by the rectum. I soon found I had no bougies small enough to pass the stricture, and, as he urgently requested an operation, saying that he could not and would not live any longer in that condition, I intended to perform a gastrostomy, but, succeeding in procuring a very small whalebone probe, I managed to pass it, after which he could manage to retain liquid if a very small amount was given. Following up my advantage, I had a series of double-bulbed bougies made and soon had this stricture dilated to a No. 12. He then became impatient and left the hospital, able, however, to drink milk. I did not see anything further of him for nearly two weeks, when I was sent for and found him again unable to swallow even water. It was with the greatest difficulty and perseverance that I passed my smallest probe and afterward dilated the stricture gradually to a No. 22. Then he passed out of my care, retaining two of my bougies, which he had learned to pass himself. He could swallow semi-solid foods and even eat meat, but only in very small quantities, finely chewed, and washed down with water and milk. He had grown fat and strong and weighed more than ever before in his life, and was very content to keep along in the way he then was. I am satisfied that I could have dilated to a much larger number, but he thought he was well enough and could not spare the time.

Case III.—This was a child, two and one-half years old, who had accidentally swallowed less than a teaspoonful of red-seal lye four weeks before I saw him. Following the swallowing of the lye he could not eat anything for three days; then he began to eat and nothing serious was suspected for three weeks, at which time he could swallow only milk. This condition persisted up to the date of his first visit to my office. Attempting to pass a large bougie I was unsuccessful, but the small No. 6 passed readily and I was able to dilate it gradually at subsequent attempts up to No. 28 French. I then supplied the parents with a rectal tube of this size and they pass it at intervals sufficient to maintain patency. The child gained rapidly after the first dilatation.

Case IV.—C. M., who is now twenty-four years of age, swallowed, when two years old, a small amount of lye and as a result had a very sore mouth, but had no bad results so far as subsequent nutrition was concerned until after an attack of scarlet fever and diphtheria when six years old. From then on he was obliged to live on milk and soft bread or potatoes, being unable to swallow anything that was in the least hard or that needed chewing. Since the age of twenty he has had no teeth, they having all decayed or dropped out, partly, no doubt, from improper nutrition owing to his limited diet and partly through disuse. I first saw this patient in December, 1897, and at the first attempt to pass an esophageal bougie was unable to introduce even the smallest size, not even the filiform, until after three or four attempts. It took a great amount of care and patience in this case to gradually dilate the stricture up to No. 18 owing to its long standing and extreme resistance to dilatation. This stricture was very near the cardiac end of the esophagus. Owing to his leaving the city I never had an opportunity to dilate to any larger size, but in June, 1899, he called at my office and informed me he was able to eat meat, chicken, veal, bread, potatoes, etc.

Case V.—Mrs. A., aged fifty years, was referred to me by Dr. T. E. Griffiths. On September

4, 1898, she had swallowed lye which had accidentally dripped into a pie, one teaspoonful of the juice being taken and producing immediate caustic effect, blanching the mucous membrane of lips, tongue and pharynx. Milk being the only thing obtainable at the time it was given in large quantities. The stomach-tube was passed and washing of the stomach was attempted, but the food which had recently been taken plugged the tube and rendered it useless. One-tenth of a grain of apomorphine was given hypodermically and free emesis was produced, accompanied, however, by marked prostration. The following day she complained of pain over the pit of the stomach and on deglutition. On September 22d she called on Dr. Griffiths complaining of constant regurgitation of food, which could not be taken and retained unless chewed very thoroughly and taken slowly and with considerable quantity of liquid. The condition grew steadily worse till December 1st, when small quantities of liquid food only, and that very slowly, could be taken. She had two strictures, one about two or three inches from the base of the tongue and the other about six inches farther down the latter, seeming to extend a distance of nearly two inches. When she was referred to me it was with difficulty that I succeeded in introducing the smallest bougie, but having finally succeeded in doing so the subsequent passage at intervals of two or four days of gradually-increasing sizes enabled me to dilate it to about No. 26, after which time, being able to swallow solid food, she disappeared from my care, having already gained materially in weight.

Case VI.—This case hardly deserves to come under a report of personal cases as I know very little about him. He was the husband of the patient referred to as Case V. and acquired his stricture at the same time, both having swallowed the lye supposing it to be the juice of the pie. His wife told me his stricture was just as bad as hers, but for some reason he would not come to my office, so that as I succeeded in passing a bougie in Case V. she would take the same bougie home and pass it on her husband so that his stricture was dilated at the same time and she informed me that he was able to eat solid food again.

Case VII.—W. B., age six years, in August, 1898, swallowed a mixture of Babbit's lye and ammonia, quantity not known. On September 24th, about four weeks subsequently, he was brought to my office to decide as to necessity for operation. He was then much emaciated and able only with great difficulty to swallow liquids. I failed entirely on that day and again on September 26th to pass even a filiform bougie. On September 28th I was able to pass a filiform bougie for a distance of about eight inches. On September 30th I had increased the size to No. 8 of the French scale, but caused a very slight amount of bleeding and this was followed by considerable pain. By October 7th I had passed a No. 12 and so continued slowly to increase the size until by October 30th a No. 24 was passed. A small rectal tube was secured and his parents passed it once every week or two without any difficulty and as the child was able to eat all kinds of food and had gained rapidly in health and flesh they considered him cured and I have not seen him since, though the father told me one month since that the boy was all right.

Case VIII.—L. F., aged thirty-seven years, on July 27, 1900, swallowed a large amount of lye mixed with whiskey with suicidal intent. She was taken to Charity Hospital in an ambulance. Her stomach was washed out and citric acid administered. Morphine was given for pain. On July 29th she left the hospital. On September 29th she was sent to the hospital by her attending physician for a gastrostomy. She was in a pitiable condition, being unable to swallow even fluids and had decreased in weight from 127 pounds to 94 pounds. I did not succeed the first day in passing the filiform bougie, but on October 1st passed it, and from that time to October 16th passed a bougie daily, increasing the size slowly till I succeeded in reaching a No. 26. The patient was rapidly gaining in flesh, being able to eat the regular hospital meals. Finding herself, as she supposed, entirely well she soon became intractable and left the hospital without permission October 16th.

I present these cases and this simple method of treatment, believing that the early adoption of this method of graduated double-bulbed bougies will, in a great many cases, render the performance of gastrostomy and retrograde dilatation unnecessary, even in some of the most serious cases.

"WHAT IS THE USE OF MAKING A DIAGNOSIS IN NERVOUS DISEASES, SINCE NOTHING CAN BE DONE ANYWAY?"[1]

BY THEODORE DILLER, M.D.,
OF PITTSBURG.

THIS question is often asked, sometimes in jest, sometimes in earnest, and sometimes, I regret to say, with a sneer. In attempting a brief answer to it I shall disregard him who asks with a sneer and him who jokes, and address myself only to the serious man—and I see none other here tonight.

Those who ask this question believe that nervous diseases, at least those which are chronic, are incurable, and therefore contend that a discriminating diagnosis has no practical value. Some look on the neurologist as a pleasant enough gentleman, oftentimes chiefly or wholly engaged in the domain of pure science or pure speculation, much given to hair-splitting definitions, industrious enough, inordinately fond of new terms, diligent in his search for a diagnosis, and absolutely

[1] Read at the second annual banquet of the Physicians' Club of New Castle, Pa., August 20, 1901.

powerless and strangely disinterested when it is made.

The end of all our diagnosis, it is contended, is treatment; and this is true enough so far as it goes. But besides his duties in attempting to effect a cure, arrest or alleviation of the disease, a most important duty devolves upon the physician in making a prognosis and in giving advice calculated to protect the patient, his family, and the community generally from the results of the disease. With the prevention of nervous diseases, I do not propose to deal. Unfortunately, at the present time, the individual practising physician can do little or nothing toward this great end.

It is unfortunately true enough that many nervous diseases are thoroughly chronic and incurable; but of these there are only a few which may not in some degree—and sometimes in a large degree—be arrested or alleviated; and we must not forget that treatment of disease should include not only efforts to cure, but also those to arrest or alleviate. Indeed, it seems to me that the resources of the physician are much more and better tested in his management of chronic diseases than in his treatment of the so-called acute and curable diseases; for the latter all in themselves tend to effect a cure. We have only four or five specifics. According to Prof. Osler there are only a small number of typhoid-fever patients in whom the favorable outcome may be fairly attributed to the intelligent efforts of the physician. It seldom or never happens that the physician cannot, in truth, hold out some reasonable hope to the sufferer from chronic disease. A hope which, to a man in sound health, perhaps, would seem meager, indeed, is often, happily and mercifully, much to the victim of chronic disease.

No one can so well minister to the hope within the chronic invalid as the physician; and when the patient sees that the physician is bravely and hopefully fighting the disease with all his power, a comfort comes to him which can in no other way be obtained.

If we take, for example, such a chronic disease as tabes dorsalis, much can often be done in the way of arresting and alleviating the disease—so much indeed that I believe the physician's efforts here often count for more than they do in the so-called acute curable diseases. I have seen comfort brought to sufferers from paralysis agitans and progressive spinal muscular atrophy by the purely negative assurance that the patient need fear neither the advent of pains nor mental symptoms. In paralytic dementia, perhaps the most uniformly fatal of diseases, the patient is mercifully, as a rule, happy and contented; and here the friends can be safely assured that the patient is entirely unaware of his fatal malady and will go on to the end without pain.

Turning now from the question of treatment of chronic nervous diseases to the consideration of questions concerning the patient's social and business relations and the welfare of his family, we have brought before us at once problems of the most vital importance, for the proper answer of which a correct diagnosis (with a reasonable prognosis) is of vital importance.

There is certainly imposed upon the physician a grave responsibility when he is called upon to make a diagnosis in the case of any of the chronic nervous diseases. For such a diagnosis, with its attendant prognosis, means much or everything to the patient and his family—physically, mentally, socially, and financially. The sooner the disease is recognized, so much the better for the patient, his family, and physician, and for the reasons apart from actual treatment of the disease, *viz.*, that the patient and his family may accordingly shape their future course in the wisest manner. The non-recognition, on the other hand, may mean useless expense to the patient in the way of treatment, financial losses by continuance in business, foolish or extravagant expenditures, or failure to cut down expenditures or contemplated enterprises in a manner which would have been prudent had it been known that an incurable progressive disease existed.

The financial questions alone in these cases are of great importance, and the recognition of the chronic disease may sometimes mean the saving of a fortune. Many fortunes have been wholly or partially wrecked before the disease was recognized and appropriate measures instituted. I once examined a patient well advanced in paralytic dementia who, upon the advice of his physician, had spent two-thirds of his fortune in traveling with his wife through Europe in search of health; and I have known other cases where paretics spent much money in useless travel abroad, foolish purchases, and in the promotion of absurd ideas. A few years ago I saw a woman in whom the symptoms of paralytic dementia were all too clear. Her husband, who had, by hard saving, accumulated a little home, was strongly bent upon sacrificing it that he might place his wife in an expensive private sanitarium. He was told the fatal character of the disease and advised to procure a caretaker and keep his wife at home. He secured a woman attendant whom he paid $5 a week; and when his wife died a year later he still had his little home.

When we come to consider tabes dorsalis, the catalogue of errors in diagnosis which have been made are as numerous as the many types of this protean malady. Ptosis, optic atrophy, paralysis of bladder, gastric crises, and darting pains in the legs have all been treated separately as though diseases in themselves when they were only symptoms of tabes. In the presence of any of these symptoms it is always well for the physician to ask himself whether tabes be not present. A correct diagnosis can save meddlesome and useless treatment and needless expense—indeed, sometimes the distress which follows complete financial wreckage—to say nothing of the vantage point it gives the patient or his friends to shape his course for the future. I think it must be admitted that the correct diagnosis is "of use" even if, for the sake of the argument, it be admitted that "nothing can be done" by treatment.

Again, a diagnosis is "of use" for the reason that some nervous diseases—too few, I regret to say—are curable and in all of them proper treatment is of the greatest importance. I need only mention the various forms of neuritis, brain abscess, myelitis, meningitis, cerebrospinal syphilis, and several of the insanities, chorea, hysteria, and neurasthenia. It is quite as unfortunate to make the diagnosis of a chronic nervous disease when none exists as is the contrary error. Every now and then we see multiple neuritis mistaken for tabes dorsalis; and many of the reported cures of the latter disease are really cases of neuritis. The non-recognition of brain abscess, when there are sufficient symptoms to indicate its presence, is a serious error, since proper treatment, *viz.*, operation, is often the means of saving life.

While the diagnosis of nervous diseases is "of use" to the patient and his family from the standpoints of treatment and prognosis, it is also "of use" to the physician himself, in saving him from the reproach which often attaches to an incorrect or long-delayed diagnosis. Moreover, for the sake of his own mental training and his conscience, the physician should always endeavor to arrive at a correct diagnosis. On this ground alone it is worth while to make a correct diagnosis in cases of nervous disease.

I believe that from the study of nervous diseases a man may obtain a peculiar mental training, hardly to be had in any other way, in the powers of observation and logical deduction that is of the greatest value to him in the diagnosis of all other diseases. The study of nervous diseases is to the physician what the study of Latin and Greek is to the college student; it gives general training of the mind and has a wide range of applicability in all his study and work.

It not rarely happens that the diagnosis of a nervous disease is beset with many difficulties; and each of us could doubtless tell of a list of blunders; my own list, I confess, is long. On account of many of these errors, but little blame can be attached to the physician if he has made an honest effort; for many nervous diseases present a very variable picture and others occur so rarely that a case may be seen only once in many years of practice. But there is one blunder which a few physicians make to which nothing but censure can, I believe, be attached. I refer to the blunder of treating a patient week after week or month after month without making a diagnosis at all or making the diagnosis (which is the same thing) of "some obscure nervous disease," without seeking the counsel of a brother physician and with the lame excuse that there is "no use in making a diagnosis in nervous diseases, since nothing can be done anyway."

Whooping Cough's Ravages in New Guinea.—The report of Lieutenant-Governor of British New Guinea states that owing to the introduction from Samar of whooping cough by two white children lives innumerable have been and are still being sacrificed.

A PRELIMINARY NOTE ON THE STERILIZATION OF CATHETERS: A BACTERIOLOGICAL STUDY.

BY C. B. NANCREDE, M.D.,
AND
W. H. HUTCHINGS, M.D.,
OF ANN ARBOR, MICH.

The title of this communication strictly defines the scope of the paper, it being merely a preliminary note, not a completed study of a very complicated subject.

Many observers have instituted investigations on the same lines, but the varying results obtained emphasize the important fact that, although in many instances sterilization is readily effected, under other, apparently identical, conditions failure has resulted. A number of our experiments show the uncertainty in respect to the time requisite for the action of sterilizing agents and plainly demonstrate that all of us must have often employed unsterilized catheters when believing the reverse to be true.

It can hardly be doubted that, if a new catheter is used for each patient, provided it is mechanically cleansed with care before and after using and kept in a supposedly germicidal solution, asepsis—or at least an inhibited condition of any germs present—will be practically secured. Unfortunately, too often the same catheter is employed for a number of patients. A little blood, mucus or muco-pus coagulates or partially dries in the lumen of the instrument, many makes of which are so constructed as to favor such accumulations, and the catheter is simply rinsed off in a perfunctory manner, laid aside only to be thrown for a few moments into a solution of a reputed chemical germicide, and is then confidently inserted into the healthy bladder of a new patient.

The details of the sixty-five experiments will not be given here. The methods of contamination will be stated, those employed to determine success or failure given, the sterilizing agents employed mentioned, and the lessons taught formulated, so far as the evidence warrants dogmatic statements. It is proposed to continue our observations in order to correct any errors, as well as to add force to our present conclusions if they prove to be well founded.

To insure as uniform results as possible, tubes of bouillon, to which a known quantity of one of the varieties of germs recognized as causative of cystitis had been added, were incubated for from twenty-four to forty-eight hours. New catheters were then immersed in this infected bouillon for five minutes, drained, and carefully and aseptically dried. After being subjected to the sterilizing agents, pieces of these infected catheters, or whole catheters, were introduced into sterilized receptacles containing culture media and incubated for from twenty-four to forty-eight hours. The germs employed were the staphylococcus pyogenes aureus, the bacillus pyocyaneus, the bacillus coli communis, and the streptococcus pyogenes. Those wishing to

study our methods *in extenso* will find appended to this report a brief account of all experiments to date. Owing to certain inherent difficulties in neutralizing carbolic acid, our experiments with this agent are not yet completed.

The most superficial study of cystitis will show how important the question of efficient sterilization of catheters has become, for such a study will show that a large majority of inflammations of the bladder result from infection conveyed by a surgically-unclean catheter, sound or bougie, hence are preventable. Although these instruments may, indeed, be contaminated by non-sterilized hands, the infected external genitalia of the female, or the urethra—especially from the latter in the male—yet all such sources of infection may be easily eliminated, while the sterilization of instruments is certainly often not attained. The desiderata in the way of sterilization of catheters are certainty, rapidity, and availability, for in private practice facilities readily obtainable in a hospital are rarely available.

None can question the superiority of heat for purposes of sterilization, especially moist heat, which if properly employed will secure perfect asepsis, yet with all the alleged certainty and facility with which this agent can be employed, Experiments 18, 27, 36 and 38 show that we can readily fall into error, and that a catheter thus imperfectly sterilized if tied into a bladder in order to maintain permanent drainage is extremely liable to give rise to cystitis.

The certainty with which metal and glass catheters can be sterilized by prolonged boiling is well known, but it is not believed by most that any soft rubber (Nelaton) catheter and most English (elastic) catheters can also be repeatedly boiled for five or more minutes without impairing their polish, strength or ductility.

Unfortunately, the chemical method of sterilizing catheters is the one too commonly employed for all varieties of instruments. We say, unfortunately, because too often it is inefficient in securing genuine asepsis as instanced by Experiments 60, 61, 62 and 63. Moreover if these chemical agents are not completely removed from the lumen of the instruments, practical cauterization of the deep urethra occurs or intense irritation of the bladder follows, as we have seen in more than one instance. It will now best serve the objects we have in view to read the conclusions arrived at, and then make a few comments of practical clinical value.

1. An infected soft rubber catheter cannot be completely sterilized by boiling under four and one-half minutes.

2. Mechanical cleansing from all dried pus, coagulated blood or mucus will render sterilization easier and will demand a shorter time to be effective.

3. Elastic (English web) catheters and soft rubber catheters can be repeatedly boiled for five or more minutes without roughening of their surfaces or diminution of their elasticity and strength.

4. Chemical sterilization by immersion in a 1:2000 mercuric chloride solution for five minutes does not sterilize any variety of catheter *which has become infected,* at best only inhibiting the growth of the germs, for if the mercuric salt be precipitated by ammonium sulphide the germs will grow freely when implanted in culture media, as shown in Experiments 60 to 63.

5. The results of experiments, as stated in the previous conclusion, indicate that chemical sterilization should never be employed for catheters which are to be retained in the bladder for any length of time, unless subjected to a very prolonged action of the mercurial salt, lest the merely inhibited germs develop.

6. Should corrosive sublimate be employed for the sterilization of catheters, it must be in a concentrated solution and the catheter must remain in it for a much longer time than the usual period considered amply sufficient in the laboratory, no mere washing with any chemical solution being efficient for *an infected instrument.*

7. Formalin vapor will sterilize infected instruments in twenty-four hours (see Experiment 64); how much shorter time will be sufficient we have not as yet determined but propose to do so in the future.

8. All methods of sterilization commonly employed should be continued for much longer periods than the minimum time required for destruction of germs in the laboratory.

9. English web catheters can apparently be more readily sterilized by heat than can soft rubber catheters, probably on account of their interior construction.

In commenting upon these tentative conclusions which we believe our experiments warrant us in drawing, we would point out that the germs employed are probably even less resistant to sterilizing agents than are those of the same species actually contaminating catheters which have been employed for cases of cystitis, because of the well-known loss of virulence of germs long cultivated upon artificial media. We propose to remedy this defect in our future experiments by procuring germs from actual cases of cystitis, when we will doubtless recognize the justice of the statement of Guyon to the effect that to insure sterilization of an infected catheter thirty minutes' boiling is requisite.

The object of this preliminary note will have been secured if the attention of the profession is called to the fact that we are often deluding ourselves by overlooking the vastly different results secured in the laboratory, where every individual germ is equally exposed to the action of the germicidal agent, and the usually very opposite conditions embarrassing us in practice; the great difference existing between the virulence of two different specimens of the same species of germs; and that apparent destruction of germs may mean only their inhibition, which is equivalent to the statement "that under peculiar circumstances these germs may multiply to a dangerous extent."

Conclusions founded upon such incorrect data unfortunately lead to disastrous results in practice, many a case of fatal cystitis following the loss of faith of practitioners in the efficacy of the precautions advocated by prominent men, the error not being in the methods, but because those teaching them are not bacteriologists as well as surgeons, hence do not appreciate the importance of many of the minute details which are the precautions necessary to eliminate not the usual but the *unusual* causes of failure.

"A little knowledge is a dangerous thing," and it ill befits any one not thoroughly versed in bacteriological investigations to either belittle the work of such surgeons or needlessly vary from the directions which they insist must be followed to secure the best results.

Experiments with Sterilization of Catheters.

Germs used in these experiments were pure cultures of colon bacillus, staphylococcus pyogenes aureus, and bacillus pyocyaneus and streptococcus pyogenes, obtained from the Hygienic Laboratory. Known quantities of these germs were put in bouillon and grown in incubator at 37.5° C. for twenty-four hours. The catheters used were immersed in these cultures for five minutes, were then removed with sterile instruments, and placed in sterile dishes and allowed to dry. They were then subjected to the sterilization process after which they were placed in sterile bouillon and incubated twenty-four to forty-eight hours.

Experiment No. 1.—Catheter inoculated with streptococcus pyogenes boiled ½ minute showed growth at end of twenty-four hours;

Experiment No. 2.—Catheter inoculated with streptococcus pyogenes boiled 1 minute showed growth at end of twenty-four hours;

Experiment No. 3.—Catheter inoculated with streptococcus pyogenes boiled 1½ minutes showed no growth at end of twenty-four hours;

Experiment No. 4.—Catheter inoculated with streptococcus pyogenes boiled 2 minutes showed no growth at end of twenty-four hours;

Experiment No. 5.—Catheter inoculated with streptococcus pyogenes boiled 2½ minutes showed no growth at end of twenty-four hours;

Experiment No. 6.—Catheter inoculated with streptococcus pyogenes boiled 3 minutes showed no growth at end of twenty-four hours;

Experiment No. 7.—Catheter inoculated with streptococcus pyogenes boiled 3½ minutes showed no growth at end of twenty-four hours;

Experiment No. 8.—Catheter inoculated with streptococcus pyogenes boiled 4 minutes showed no growth at end of twenty-four hours;

Experiment No. 9.—Catheter inoculated with streptococcus pyogenes boiled 4½ minutes showed no growth at end of twenty-four hours;

Experiment No. 10.—Catheter inoculated with streptococcus pyogenes boiled 5 minutes showed no growth at end of twenty-four hours;

Experiment No. 11.—Catheter inoculated with colon bacillus boiled ½ minute showed growth at end of twenty-four hours;

Experiment No. 12.—Catheter inoculated with colon bacillus boiled 1 minute showed no growth at end of twenty-four hours but did at end of forty-eight hours;

Experiment No. 13.—Catheter inoculated with colon bacillus boiled 1½ minutes showed no growth at end of twenty-four hours but did at end of forty-eight hours;

Experiment No. 14.—Catheter inoculated with colon bacillus boiled 2 minutes showed no growth at end of twenty-four hours but did at end of forty-eight hours;

Experiment No. 15.—Catheter inoculated with colon bacillus boiled 2½ minutes showed no growth at end of twenty-four hours but did at end of forty-eight hours;

Experiment No. 16.—Catheter inoculated with colon bacillus boiled 3 minutes showed no growth at end of twenty-four hours and no growth at end of forty-eight hours;

Experiment No. 17.—Catheter inoculated with colon bacillus boiled 3½ minutes showed no growth at end of twenty-four hours and no growth at end of forty-eight hours;

Experiment No. 18.—Catheter inoculated with colon bacillus boiled 4 minutes showed no growth at end of twenty-four hours, showed growth at end of forty-eight;

Experiment No. 19.—Catheter inoculated with colon bacillus boiled 4½ minutes showed no growth at end of twenty-four hours, showed no growth at end of forty-eight hours;

Experiment No. 20.—Catheter inoculated with colon bacillus boiled 5 minutes showed no growth at end of twenty-four hours, no growth at end of forty-eight hours;

Experiment No. 21.—Catheter inoculated with staphylococcus pyogenes aureus boiled ½ minute showed growth at end of twenty-four hours;

Experiment No. 22.—Catheter inoculated with staphylococcus pyogenes aureus boiled 1 minute showed no growth at end of twenty-four hours;

Experiment No. 23.—Catheter inoculated with staphylococcus pyogenes aureus boiled 1½ minutes showed no growth at end of twenty-four hours, no growth at end of forty-eight hours;

Experiment No. 24.—Catheter inoculated with staphylococcus pyogenes aureus boiled 2 minutes showed no growth at end of twenty-four hours, no growth at end of forty-eight hours;

Experiment No. 25.—Catheter inoculated with staphylococcus pyogenes aureus boiled 2½ minutes showed no growth at end of twenty-four hours, no growth at the end of forty-eight hours.

Experiment No. 26.—Catheter inoculated with staphylococcus pyogenes aureus boiled 3 minutes showed no growth at end of twenty-four hours, no growth at end of forty-eight hours;

Experiment No. 27.—Catheter inoculated with staphylococcus pyogenes aureus boiled 3½ minutes showed no growth at end of twenty-four hours, growth at end of forty-eight hours;

Experiment No. 28.—Catheter inoculated with

staphylococcus pyogenes aureus boiled 4 minutes showed no growth at end of twenty-four hours, no growth at end of forty-eight hours;

Experiment No. 29.—Catheter inoculated with staphylococcus pyogenes aureus boiled 4½ minutes showed no growth at end of twenty-four hours, growth at end of forty-eight hours;

Experiment No. 30.—Catheter inoculated with staphylococcus pyogenes aureus boiled 5 minutes showed no growth at end of twenty-four hours, no growth at end of forty-eight hours;

Experiment No. 31.—Catheter inoculated with bacillus pyocyaneus boiled ½ minute showed growth at end of twenty-four hours;

Experiment No. 32.—Catheter inoculated with bacillus pyocyaneus boiled 1 minute showed growth at end of twenty-four hours;

Experiment No. 33.—Catheter inoculated with bacillus pyocaneus boiled 1½ minutes showed no growth at end of twenty-four hours, showed growth at end of forty-eight hours;

Experiment No. 34.—Catheter inoculated with bacillus pyocyaneus boiled 2 minutes showed no growth at end of twenty-four hours, growth at end of forty-eight hours;

Experiment No. 35.—Catheter inoculated with bacillus pyocyaneus boiled 2½ minutes showed no growth at end of twenty-four hours, growth at end of forty-eight hours;

Experiment No. 36.—Catheter inoculated with bacillus pyocyaneus boiled 3 minutes showed no growth at end of twenty-four hours, growth at end of forty-eight hours;

Experiment No. 37.—Catheter inoculated with bacillus pyocyaneus boiled 3½ minutes showed no growth at end of twenty-four hours, no growth at end of forty-eight hours;

Experiment No. 38.—Catheter inoculated with bacillus pyocyaneus boiled 4 minutes showed no growth at end of twenty-four hours, no growth at end of forty-eight hours;

Experiment No. 39.—Catheter inoculated with bacillus pyocyaneus boiled 4½ minutes no growth at end of twenty-four hours, no growth at end of forty-eight hours;

Experiment No. 40.—Catheter inoculated with bacillus pyocyaneus boiled 5 minutes showed no growth at end of twenty-four hours, no growth at end of forty-eight hours;

Experiment No. 41.—Inoculated English (web) catheter with colon bacillus boiled ½ minute showed no growth at end of forty-eight hours;

Experiment No. 42.—Inoculated English (web) catheter with colon bacillus boiled 1 minutes showed no growth at end of forty-eight hours;

Experiment No. 43.—Inoculated English (web) catheter with colon bacillus boiled 1½ minutes showed no growth at end of forty-eight hours;

Experiment No. 44.—Inoculated English (web) catheter with colon bacillus boiled 2 minutes showed no growth at end of twenty-four hours;

Experiment No. 45.—Inoculated English (web) catheter with staphylococcus pyogenes aureus boiled ½ minute showed no growth at end of forty-eight hours;

Experiment No. 46.—Inoculated English (web) catheter with staphylococcus pyogenes aureus boiled 1 minute showed no growth at end of forty-eight hours;

Experiment No. 47.—Inoculated English (web) catheter with staphylococcus pyogenes aureus boiled 1½ minutes showed no growth at end of forty-eight hours;

Experiment No. 48.—Inoculated English (web) catheter with staphylococcus pyogenes aureus boiled 2 minutes showed no growth at end of forty-eight hours;

Experiment No. 49.—Inoculated English (web) catheter with staphylococcus pyogenes aureus boiled 2½ minutes showed no growth at end of forty-eight hours;

Experiment No. 50.—Inoculated English (web) catheter with streptococcus pyogenes boiled ½ minute showed no growth at end of forty-eight hours;

Experiment No. 51.—Inoculated English (web) catheter with streptococcus pyogenes boiled 1 minute showed no growth at end of forty-eight hours;

Experiment No. 52.—Inoculated English (web) catheter with streptococcus pyogenes boiled 1½ minutes showed no growth at end of forty-eight hours;

Experiment No. 53.—Inoculated English (web) catheter with streptococcus pyogenes boiled 2 minutes showed no growth at end of forty-eight hours;

Experiment No. 54.—Inoculated English (web) catheter with streptococcus pyogenes boiled 2½ minutes showed no growth at end of forty-eight hours;

Experiment No. 55.—Inoculated English (web) catheter with bacillus pyocyaneus boiled ½ minute showed no growth at end of forty-eight hours;

Experiment No. 56.—Inoculated English (web) catheter with bacillus pyocyaneus boiled 1 minute showed no growth at end of forty-eight hours;

Experiment No. 57.—Inoculated English (web) catheter with bacillus pyocyaneus boiled 1½ minutes showed no growth at end of forty-eight hours;

Experiment No. 58.—Inoculated English (web) catheter with bacillus pyocyaneus boiled 2 minutes showed no growth at end of forty-eight hours;

Experiment No. 59.—Inoculated English (web) catheter with bacillus pyocyaneus boiled 2½ minutes showed no growth at end of forty-eight hours;

Experiment No. 60.—Inoculated English (web) catheter with colon bacillus placed in bichloride of mercury, 1 to 2,000, for five minutes; rinsed thoroughly in sterile water, put in bouillon into which gas generated by heating

ammonium sulphide was passed through a sterile tube, thus forming a compound which is neutral to bacteria. Put in incubator, growth at end of twenty-four hours;

Experiment No. 61. — Inoculated English (web) catheter with staphylococcus pyogenes aureus and bacillus pyocyaneus was placed for five minutes in 1:2,000 bichloride-of-mercury solution; was then thoroughly rinsed in sterile water, was placed in bouillon through which gas generated by heating ammonium sulphide was passed through a sterile tube. Placed in incubator. At end of twenty-four hours growth occurred;

Experiment No. 62. — Inoculated English (web) catheter with bacillus pyocyaneus was placed for five minutes in 1:2,000 bichloride-of-mercury solution, was then thoroughly rinsed in sterile water, placed in bouillon through which gas generated by heating ammonium sulphide was passed through a sterile tube. Placed in incubator, growth occurred at end of twenty-four hours;

Experiment No. 63. — Inoculated English (web) catheter with streptococcus pyogenes placed in bichloride of mercury, 1:2,000, for five minutes; rinsed thoroughly in sterile water, put in bouillon into which gas generated by heating ammonium sulphide was passed through a sterile tube, incubated, growth was observed at end of twenty-four hours;

Experiment No. 64.—English (web) inoculated with colon bacillus dried by passing air over it which has been aspirated through sulphuric acid, put in vapor formaldehyde twenty-four hours; there was no growth at end of twenty-four hours;

Experiment No. 65.—English (web) catheter boiled in tap water five minutes at a time on ten successive days, was in as good condition as in the beginning.

HYGIENE AND HYGIENIC LEGISLATION.

BY W. SCHEPPEGRELL, A.M., M.D.,

OF NEW ORLEANS, LA.;

EX-VICE-PRESIDENT OF THE AMERICAN LARYNGOLOGICAL, RHINOLOGICAL AND OTO-LARYNGOLOGICAL ASSOCIATION; EX-PRESIDENT OF THE WESTERN OPHTHALMOLOGIC AND OTO-LARYNGOLOGIC ASSOCIATION, ETC.

As bacteriology has traced out the origin of one infectious disease after another, it has also pointed out the intelligent means of combating disease. If tuberculosis of the lungs is due to the presence and activity of Koch's bacillus in the pulmonary tissue, and if the bacillus outside of the body is chiefly found in the sputum of persons affected with this disease, and if the inhalation of the dried product of such sputum is capable of infecting persons susceptible through inheritance, lowered vitality or other causes, to tuberculous disease, then the duty of the hygienist is clearly defined. These premises have been clearly demonstrated and are now accepted by the medical profession; hence it is our duty to use every means in our power to destroy the infectious character of the sputum, and to minimize its distribution where it can effect harm. Among the latter methods none is more valuable than the "Municipal Control of the Spitting Habit."

The potentiality for evil due to promiscuous expectoration in public halls, theaters and other places of amusement, is recognized by physicians generally, but it is accepted with incredulity by a large majority of the laity. This is principally due to the fact that the masses believe that tuberculosis, which is the principal and most fatal disease that may be conveyed in this manner, is due entirely to inheritance, not realizing that inheritance in these cases may mean simply a susceptibiiity and that infection is the main cause of one member after another of the family being affected by the disease when once it has developed in the household. Another potent reason for this incredulity is that the incubation of tuberculous disease is so long that the connection between the cause and effect is difficult and sometimes impossible to trace. Clinical experience, bacteriological research and physiological experiments have, however, established these facts so firmly, that they have been generally accepted by the medical profession.

As illustrating the present tendency toward hygienic advancement, we find that some cities have already enacted laws prohibiting promiscuous expectoration among which are the following: New York and Brooklyn, Newark, Columbus, Cleveland, San Francisco, Pittsburg, Washington, D. C., Rochester, Louisville, and Baltimore. Within the last month New Orleans has been added to this list, and as the history of this hygienic victory may not be without interest, and as, moreover, it may encourage other efforts in this direction, the main points of the discussion will be given.

On February 20, 1901, I read before the Orleans Parish Society a paper entitled "Dust as a Factor in Diseases of the Upper Respiratory Passages," in which I called attention, among other considerations, to the danger of contracting disease from the inhalation of dust infected with sputum of persons suffering from tuberculosis and other diseases. After the conclusion of this paper, the society unanimously passed resolutions favoring the municipal regulation of the spitting habit, and appointed a committee to urge the City Council of New Orleans to enact an ordinance protecting citizens from the injurious effects of promiscuous spitting and expectoration. On March 4, 1901, the president appointed Drs. Scheppegrell and Storck to this committee. At the date of the appointment of this committee there was pending before the City Council the Moss ordinance which practically covered the regulations desired by the Orleans Parish Medical Society, and the committee quietly awaited developments as its passage would secure the desired object. This ordinance was passed by the City Council. At the next meeting, however, it was vetoed by the Mayor,

the City Council sustaining his veto, and the ordinance was defeated. A few days later this committee, accompanied by Dr. William Brickell, called on the Mayor and expressed its regret that he should have found it necessary to veto an ordinance to which the committee attached such importance, and requested to know what his objections were. The Mayor, in the most courteous manner, explained that he had vetoed the ordinance on account of the impossibility of enforcing that part which referred to sidewalks. Without admitting the validity of this objection, the committee enquired if, this feature being omitted, he would no longer oppose the enactment of this ordinance, to which the Mayor agreed.

Having had the ordinance prepared in the regular legal manner by the City Attorney, it was placed in the hands of Councilman O'Connor to be introduced at the next meeting of the Council. In the meanwhile, a circular letter was sent to each councilman, explaining the hygienic value of the proposed ordinance, and requesting for it a favorable consideration.

At the next meeting of the Council, Mr. O'Connor, as agreed, introduced the ordinance which, according to rule, was referred to the "Committee on Law and Order." At the meeting of this committee, the amendment referring to "sidewalks and banquettes" was introduced, which had been the cause of the Mayor's veto in the previous (Moss) ordinance. I had a conference with Mayor Capdevielle on this subject, and he stated that if this amendment were left he would again use his veto power to defeat the ordinance.

I made an effort to have this amendment omitted, not because it was not an excellent provision, but because it jeopardized the passage of the entire ordinance. This proved unavailing, however, and it was hoped that the City Council would take action on the Minority Report in which the amendment was omitted. This was not the case, however, and the Council passed the ordinance including the amendment.

When the report of the meeting was published the following position presented itself: As the Mayor has vetoed the previous ordinance he could consistently do but likewise to the present ordinance. If, however, this ordinance was not passed, there would be little possibility of obtaining the benefit of any part of it during the remaining three years of the present administration, as the Council had in two instances shown its determination to let the whole ordinance stand or fall on its merits. The only hope, then, was to obtain for the ordinance such a weight of public opinion and to place its advantages in so strong a light, that it would become a law in spite of all opposition. When it is understood that every newspaper of New Orleans was opposed to the ordinance and freely expressed this opinion in their editorials, it will be seen that the task was no light one.

The morning after the meeting of the Council, the *Picayune,* one of the most prominent newspapers of New Orleans, published an editorial attacking the proposed ordinance. It stated that the ordinance would cause only trouble to the people, could not be inforced and that there were many other matters of more importance which were neglected by the Council in its zeal for impracticable hygienic laws. As this offered a fair opportunity for presenting the value of the proposed ordinance, I made in the next issue the following reply, which the paper entitled "Lecture on Spit and Sputum."

"To the Editor of the *Picayune:* I note with much surprise and regret your opposition to the ordinance prohibiting the spitting on the floors of public halls, theaters and other places of amusement and on sidewalks, which was passed by the City Council last night. As the Mayor was opposed to the last clause of this ordinance, it might have been more expedient to have omitted this for the present, but there can be no question that the whole ordinance is a distinct advance in hygiene and sanitation, and thus places us in line in this direction with New York and Brooklyn, Newark, Columbus, Cleveland, San Francisco, Pittsburg, Washington, D. C., Rochester, Louisville and Baltimore, each of which has a similar law on this subject.

"That there are many other matters that require legislative regulation, as you observe, is unquestionable, but there is certainly none which is as important as the ordinance which was passed by the City Council at its meeting last night. The difficulties which have been suggested in the enforcement of such an ordinance seems to have been overestimated. In the first place, women, as a class, do not spit on the floors of public halls, theaters and other places of amusement, or on sidewalks, and yet these are the ones who suffer the most from such practices. In the second place, gentlemen do not spit on the floors of their own homes, nor will they on the floors of theaters and other places of amusement when the expectoration will soil the skirts of the ladies whom they accompany or of ladies escorted by others. For persons who are polite only when compelled by law, there is always an officer in attendance at all the theaters. This ordinance may prove a temporary hardship for those suffering from colds, etc., but it is better for them to use a few extra handkerchiefs than to soil the clothes of the lady, and endanger the health of all present. Similar hardship exists in cases of smallpox, diphtheria, scarlet fever, etc., but we rarely hear persons advocating the rescinding of these laws which are burdensome to the patient, no doubt, but which are necessary for the public welfare.

"Regarding the spitting on sidewalks, the difficulty of enforcement appears also to be overestimated. Persons do not spit on sidewalks for personal gain, as is the case with robbers, nor in a passion, as is the case of those who fight or quarrel; it is done simply from carelessness, indifference, or through ignorance of the laws of

hygiene. The very existence of such an ordinance would, therefore, be sufficient to prevent law-abiding persons from spitting on the sidewalks, just as the existence of an ordinance preventing the spitting on car floors has decreased this nuisance, although no effort has yet been made to enforce it. There is no restriction in the ordinance against using the gutters for this purpose. It should be remembered in this connection that the danger of infection from consumption and other diseases through expectoration in the open air is materially different from that in rooms, theaters, etc. In the latter, the dried infective sputum spreads with the dust and may prove a source of danger for weeks and even months. Out of doors, however, the action of the sun is to destroy the infective character of the expectorated matter, the rain to wash it away, and the winds to attenuate it so much that the risk of infection bears no comparison to the inhalation of infective dust indoors. The greatest danger, omitting the question of decency and the unpleasant impression given by the sidewalks of some of our most prominent streets, is that the expectorated material will be swept up by the skirts of the ladies who may thus not only infect themselves, but may, indirectly, form a source of infection for the entire household.

"From a hygienic standpoint, there can no longer be any doubt of the possibility of infection from the sputum of consumption and many other diseases. These are not simply theoretical deductions, but they have been established by clinical observations and by experiment. As showing the general acceptance of this subject, I will quote a few paragraphs from the report of a recent meeting of the State Board of Health:

" 'The Contagiousness of Consumption.—The erroneous idea has long prevailed that consumption is always hereditary. The disease is hereditary only in an infinitesimal proportion of cases. The fact cannot be too strongly impressed upon the public that, in almost every instance, the disease is derived from the excretions of some individual affected with consumption.

"How Consumption is Disseminated.—The cause of this malady is a microscopic germ whose scientific name is the bacillus tuberculosis. All matters expectorated by a person afflicted with consumption contain legions of these bacilli, which retain their vitality even after the drying of the sputum, and to their diffusion may be attributed the spread of the disease.

" 'By Inhalation.—The sputum is expectorated on the sidewalk, street, ground, floor of theater, schoolroom or street car—in fact, anywhere—and, after drying, mingles with the atmosphere, and may develop the disease in persons susceptible to the disease, or whose normal resistance has been lowered from illness or other cause.' "

"The Orleans Parish Medical Society also in a recent meeting, unanimously passed resolutions requesting the City Council to pass an ordinance prohibiting the spitting on the floors of public halls, theaters and other places of amusement, and appointed a special committee to further this object.

"Even if there were some difficulty in the last clause of the ordinance, it is to be hoped that the benefit of the remaining part of the ordinance will not be sacrificed by its repeal. As a matter of fact, New Orleans cannot afford to do so. To spend millions of dollars for drainage and sewerage to improve its hygiene, and then deliberately cancel a law which to the hygienist is of equal importance and costs practically nothing, would be inconsistent and would make us the subject of ridicule.

"A few days ago the following telegraphic dispatch appeared in our daily papers:

" 'The Americans are to be congratulated also on the excellent sanitary conditions throughout Havana. Modern sanitation has been carried into every house. The streets are kept scrupulously clean, garbage is systematically removed, and not only the public but all private localities are kept in the best sanitary condition. This alone speaks much for the beneficial influence which the Americans exerted.'

"It would appear from this that our missionary work is more successful and meets with less resistance than our home efforts.

"W. SCHEPPEGRELL, M.D.,

"Chairman, Committee on Hygienic Legislation,
Orleans Parish Medical Society.

"New Orleans, April 10, 1901."

In the foot-note to this communication, the editor claims that I had not read the editorial carefully, or I would have seen that the *Picayune* was not opposed to the ordinance. Without debating these premises, the statement that the *Picayune* was not opposed was a strong point gained.

Desiring to show the views of the medical profession on this subject and believing that this would be of great weight, I requested Mr. Page Baker, the editor of the *Times-Democrat,* to send reporters to interview prominent physicians on this subject, giving the names of the president of the Orleans Medical Society, the president of the State Medical Society, and others. These interviews appeared in the *Times-Democrat* the following morning, although a number of the physicians named were not interviewed, probably on account of the difficulty of finding them at leisure. While the interviews with some of the physicians gave the editor material for a vigorous editorial against the ordinance, I believe that the general effect was good, especially the interviews with Dr. Edmond Souchon, President of the Board of Health, and Prof. Rudolph Matas.

As stated, the editor of the *Times-Democrat* found sufficient material in the interviews to criticize the ordinance adversely, and this I answered the following morning (April 13th) giving a synopsis of the interviews and showing that their general tendency was in favor of the

ordinance and giving historical proofs of its practicability:

"To the Editor of the *Times-Democrat:*

"I have read with careful attention your editorial criticism of the anti-spitting ordinance in to-day's issue of the *Times-Democrat.* I also note the interviews with physicians regarding this ordinance.

"A careful criticism will show that none of those interviewed are actually opposed to the ordinance, and the great majority favor its adoption.

"After carefully analyzing the opposition that has been brought against the anti-spitting ordinance, it seems to be generally admitted, even by those who do not favor it, that the regulations are useful, but that they are difficult or impossible to enforce.

"Regarding this point, I would call attention to the fact that the amended City Ordinance No. 13,073, C. S., of February 3, 1897, prohibiting the spitting on the floors of street cars, has resulted in materially improving the condition of our cars, and yet no effort has ever been made to enforce the ordinance. The moral effect of an existing law was all sufficient.

"Referring again to your criticism, it would seem that the literature of the opposition to such an ordinance must be extremely meager when both the *Times-Democrat* and the *Picayune* can find only the same quotation, viz., the report of the cases before Magistrate Olmstead of New York. This is in reality the highest praise that could be brought in favor of the ordinance, that the two largest daily papers of the South, with their immense exchanges and facilities for intercourse, should have been able to find only this solitary objection to such a hygienic measure.

"The literature on the other side of the question, however, is much richer. The greater number of the large cities of the United States have such an ordinance, many of which have been in existence for years, among which may be mentioned, in addition to New York and Brooklyn, Newark, Columbus, Cleveland, San Francisco, Pittsburg, Washington, D. C., Rochester, Louisville, Denver, and others. Nor do we need go so far from home to find cities advanced in hygienic matters. Our neighbor, Mobile, has had such an ordinance for over a year, and is having it rigidly enforced. The effect has been excellent, and George H. Heakes, a native of Mobile, who represents a large manufacturing interest, states that it is considered a valuable regulation.

"There is no need of awaiting the experience of New York in regard to such an ordinance, as it has already been in existence for years in many cities and has caused practically no friction, as the meagerness of the evidence against its enforcement forms the best evidence. Not only have they been enforced, but they have been sustained by the courts, as in the cases before the courts of Newark and San Francisco.

"Your suggestion to have the ordinance recommitted for amendment is impracticable, as the City Council has in two instances indicated its determination to pass the complete ordinance.

"As in the case of the ordinance regulating street cars, it would require but little enforcing, and the claim that there are not sufficient police for this purpose would apply equally to the cars. Even at the utmost, one fine would have so salutary an effect that we would hear but little further of the practice, as it certainly is no great hardship for a man to spit in the gutter, instead of on the sidewalk, and this seems to be the sum total of all the objections to the whole ordinance.

"As I have elsewhere stated, we cannot afford to reject this ordinance. New Orleans is being favorably commented upon over the entire Union for its manly efforts for sanitary advancement. To reject this ordinance, the importance of which is acknowledged by all hygienists, and to spend millions of dollars for drainage and sewerage would be inconsistent. That it may make us the subject of ridicule will appear from the following quotation from an interesting article by Dr. Elmar B. Borland of Pittsburg, in the *Journal of the American Medical Association:*

" 'Poor St. Augustine! This ancient landmark answered the writer's inquiries (regarding the municipal regulation of the spitting habit) thus: "Our native people would consider such an order an insult to their dignity. Cannot stop a Florida cracker from spitting." May we interpret from this answer that these people love darkness rather than light?'

W. Scheppegrell, M.D.,

"Chairman Committee on Hygienic Legislation, Orleans Parish Medical Society.

" New Orleans, April 12, 1901. "

In the meanwhile, desiring to bring to our aid a factor which is highly interested in such a law and which suffered most from the practices which the ordinance was intended to prohibit, I requested Mrs. L. M. Horner, the energetic and public-spirited president of the Local Council of Women of New Orleans, to present to the public the woman's side of this question, and in her excellent letter on this subject in the *Times-Democrat* of the 14th she fully realized my anticipation.

The letter which I had published on April 13th was the subject of criticism in an editorial of the same issue of the *Times-Democrat*, and the editor maintained that it was impossible to enforce the ordinance prohibiting spitting on the sidewalks as it was in the street-cars.

In the issue of Sunday, the 14th, the *Times-Democrat* again published an editorial against the proposed ordinance, following generally the lines which have already been given. The following day I answered these, showing that while no efforts had as yet been made to enforce the ordinance prohibiting spitting on the floors of street-cars, it had been productive of much benefit to the community, as shown by the improved condition of our street-cars. It also called attention to the fact that some portion of the enormous death-rate from tuberculosis must be due to the

neglect of such hygienic measures and that it would, therefore, be a grave and unjustifiable responsibility to reject this ordinance on account of some possible difficulty in its enforcement:

"To the Editor of the *Times-Democrat:* I have read with care your editorial in answer to my communication in favor of the anti-spitting ordinance. I do not dispute the fact that the *Times-Democrat* has always favored sanitation and hygiene, and it is precisely on this account that I am surprised that it has taken the present position regarding the ordinance at issue. The question of whether such a law be efficacious is not a matter of personal belief; it has been demonstrated to be a fact by the majority of the larger cities, as I have shown in my last communication. That so large a daily paper, which has always been in the vanguard of every movement for the benefit of New Orleans, should clog the wheels of hygienic progress is a source of no little surprise.

"While your editorial is written in your usual concise and logical style, it has not answered the propositions which I submitted. It has discussed practically only the parallel case of the ordinance to which notice is called on the street cars. I am therefore justified in considering the other points as admitted.

"I am perfectly willing to discuss the anti-spitting ordinance, which you state should not be enacted, on the basis of the parallel case prohibiting the spitting on the floors of street cars. This ordinance, which was enacted in 1897, has caused no friction, no attempt has ever been made to enforce it, and yet it has changed the condition of our car floors from the filthy condition formerly existing to a fairly respectable appearance. Every argument which you have brought out regarding the difficulty of enforcing the new ordinance applies with equal strength to the street car ordinance, and yet the latter has been productive of much good. What could have been the cause but the moral effect of an existing law on the law-abiding citizen and the remote fear of possible detection and fine on the others.

"That the condition of the cars has been improved is not a matter of surmise. Every officer of the street railroads to whom this question has been addressed has admitted this, and so has every one else whose opinion has been requested. As a matter of fact, any attempt to rescind this ordinance would meet with a storm of indignation.

"That the law cannot be enforced under the extreme conditions which you mention is freely admitted. But how many of our most valued ordinances could stand such a test? Let me also illustrate this with an *argumentum ad hominem:* The genial editor of the *Times-Democrat* and his family have gone to the Boston Club to see the Carnival procession. The servants, taking advantage of this absence, have gone to the corner of St. Charles Avenue to see the procession pass by, and the immediate neighbors and their servants, actuated by similar motives, are also absent, and the nearest policeman is mending the wheel of his bicycle. The burglar takes advantage of this condition of affairs and robs the house of prized valuables. You would hardly countenance the rescinding of the law regarding house-breaking because it is inadequate in such cases.

"Let us show the importance of the new ordinance by making a practical application. New Orleans intends to inaugurate a great street fair in the near future. If our sidewalks are to be in the filthy condition that is usually the case on such occasions it will undoubtedly give a bad impression to the many visitors that we expect regarding the cleanliness and hygiene of New Orleans. The moral effect of a city ordinance would undoubtedly have a similar good effect as it has had in the case of the street cars. If in addition to this a few small notices similar to those in the street cars were posted in conspicuous places and showing some such notice as the following: 'Spitting on Sidewalks Unlawful, C. S. No.—' a most wholesome effect would be obtained, and it would not tax the duties of the police force.

"To limit myself to the parallel case which you have suggested, I submit it to an impartial public as to whether the ordinance prohibiting spitting on the floors of street cars has been productive of more good than evil to the city. The former has been the verdict of every one to whom this question has been addressed. Under the circumstances, the ordinance prohibiting spitting on the floors of public halls, theaters and on sidewalks should be given a fair trial. If it should be found impracticable it can always be rescinded, and we will at least gain the credit of having made an earnest attempt to improve our sanitary condition and to ameliorate the discomfort of the ladies, who are the real victims of such practices. To do otherwise might be construed as an unwillingness on our part to join the ranks of the progressive cities, which I have enumerated, that have enacted similar laws and are deriving the benefit of such sanitary regulations.

"My object in this communication was simply to answer your argument regarding the street car ordinance. In examining, however, your 'Gist of the News,' which is of great convenience to your readers, and which indicates the, with the above noteworthy exception, progressive character of the *Times-Democrat,* I note the following paragraph:

" 'Statistics show that out of 185,532 deaths in New Orleans in twenty-seven years 23,193 have been caused by consumption.'

"It is now considered beyond contradiction that consumption is a disease of infectious origin. The State Board of Health at its last meeting has voiced the opinion of the medical profession when it stated that among the causes of consumption is the inhalation of dried expectoration which has been deposited on the floors of public halls, theaters and on sidewalks. Under the circumstances it is fair to infer that a considerable number of these deaths are due to the neglect of such sanitary precautions.

"If this ordinance has in view, among other considerations, such a praiseworthy object, it should at least be given a fair trial. To reject it because there is a possibility of its being impractible would be assuming a grave and unjustifiable responsibility.

"W. SCHEPPEGRELL, M.D.,
"Chairman, Committee on Hygienic Legislation,
Orleans Parish Medical Society.

"New Orleans, April 13, 1901."

This letter ended the discussion in the *Times-Democrat,* which made no further effort to oppose the ordinance. In its issue of Sunday, April 14, 1901, the *Daily States* attacked the proposed ordinance, and, after holding it up to ridicule, called attention to the fact that I had published an article entitled, "Dust as a Factor in Diseases of the Upper Respiratory Passages," in *American Medicine,* in which I had shown the injurious effects caused by inhaling the dust from shell roads, etc., and while championing the present ordinance, I had made no attempt to prevent the city from making a contract for oyster shells for road purposes. This editorial I answered the following day, explaining that I had also stated in the article referred to that the most injurious form of dust was that contaminated by infected sputum, and that the committee of which I was chairman had been appointed specifically to aid the passage of certain hygienic laws, and could therefore not deviate from this purpose:

"To the Editor of the *Daily States:* I have read, with much interest, your editorial on 'Mankind and Its Microbes' in the Sunday *States* of the 14th issue, and noted the quotation from my article on 'Dust as a Factor in Disease of the Respiratory Organs,' published at the special request of the editor in the *American Medicine* of Philadelphia. In connection with this, I would state that only the first section of the article was published in the issue referred to as shown by the word 'Continued' at its end, and you could therefore not know that the remainder of the communication was in strong support of the anti-spitting ordinance which forms the subject of the present discussion.

"Relying, therefore, on your well-known spirit of fair play, I will request you to publish with this the portion of the article which bears on this subject, and which in substance is as follows:

" 'A source of danger from dust, which is not so conspicuous as the dust in our streets but which is far more pernicious in its effects, is in public carriers as railroads and ferries, and in public halls and in places of amusement in which hygienic laws regarding spitting on the floors is not enforced. The expectorated material mixes with the dirt of the floor, soon dries and becomes a part of the dust of the air, which is inhaled, this being especially the case in winter, when the windows are closed. Bacteriologists have repeatedly shown the presence of pathogenic microorganisms in the sweepings of floors and the possibility of contracting disease from this source is no longer disputed. When the system has been debilitated by sickness, or the normal resistance has been lowered from any source whatsoever, the chances of obtaining disease from this source is enormously increased. In my opinion, many of the deleterious after-effects of grippe, of which we now hear so much, are not due to the effects of this disease directly, but to the lowering of the vitality and normal resistance, thus allowing the entrance of pathogenic germs from such sources as I have here described.'

"In regard to my supporting the anti-spitting ordinance and neglecting other public measures of importance, I would state that while I am personally in favor of the ordinance, and am heartily in earnest in my opinion that it will react to the welfare of New Orleans, my position in this discussion is simply as the representative of the Orleans Parish Medical Society. This organization, which thoroughly represents the medical profession of this city, unanimously passed resolutions urging such hygienic laws and appointed a special committee to further this object. You will therefore understand that, as the chairman of this, I cannot officially deviate from the *raison d'etre* of this committee.

"W. SCHEPPEGRELL, M.D.,
"Chairman, Committee on Hygienic Legislation,
Orleans Parish Medical Society.

"New Orleans, April 15, 1901."

The following day, April 16th, was the date on which the Council should take its final action on the proposed ordinance, and for this date I reserved my strongest argument. I had already shown the advantages of the ordinance from a medical and from a woman's standpoint; now I showed its practicability from a legal standpoint. In a communication entitled, "The Hon. Don A. Pardee on the Anti-spitting Ordinance," I first gave a general résumé of the subject, giving the names of the cities in which it was in force, and showing that the only objection which had been brought against the ordinance had been fully answered. I then submitted the letter from Hon. Don A. Pardee, Judge of the United States Circuit Court, in which he stated that the law was enforced in Atlanta, was well thought of by all good citizens, and had caused little trouble to the police. I believe that this letter carried great weight, and it was referred to by one of the Councilmen in defending the ordinance at the meeting of Council:

"To the Editor of the *Picayune:* The ordinance prohibiting spitting on the floors of public halls and theaters and on sidewalks should come up for final consideration at the meeting of the Council to-night. The only objection that has been argued against its enactment is that it will be difficult to enforce. It has already been shown that this law has been enacted and is regarded as a valuable sanitary regulation in such cities as New York and Brooklyn, Newark, Columbus, Cleveland, San Francisco, Pittsburg, Washington, D. C., Rochester, Louisville and Baltimore,

and even our neighbor, Mobile, is enjoying its benefits. Every report regarding its operation has been in its favor except the solitary case reported by the *New York Sun*. What higher praise can be adduced of its popularity?

"In addition to the cities enumerated, I find also that Atlanta has joined the rank of hygienic progress, as shown in a letter from my esteemed friend, the Hon. Don A Pardee, Judge of the United States Circuit Court, than whose name none carries more weight in this community, and whose judgment is respected by all classes. This communication, which is inclosed with the writer's permission, reads as follows:

"'United States Circuit Court,
"'Fifth Judicial District,
"'Sunday, April 14, 1901.

"'Dear Dr. Scheppegrell: I have noticed your interest in the hygienic ordinance now pending in the City Council in relation to spitting on sidewalks and in other public places, and the opposition of the newspapers on the ground of inability of the police to enforce such an ordinance. I write this to say that such an ordinance has been in force in Atlanta for some time, and has not only been well enforced without much trouble to the police, but is well thought of by all good citizens. In fact, as the ordinance is given publicity, it substantially enforces itself, as all respect the underlying object.

"'DON A. PARDEE.'

"This letter is submitted without further comment. To the unbiased mind it answers practically and conclusively the only objection which has been brought against the ordinance.

"W. SCHEPPEGRELL, M.D.,
"Chairman Committee on Hygienic Legislation,
Orleans Parish Medical Society.
"New Orleans, April 15, 1901."

The remainder of this subject is public history. The Mayor of New Orleans vetoed the ordinance and it was passed over his veto by the necessary vote of 16 to 4. The ordinance, which is now a municipal law, reads as follows:

"*Ordinance Prohibiting Spitting on the Floors of Public Halls, Theaters and Other Places of Amusement, and on Sidewalks and Banquettes.*

"*Section 1.*—Be it ordained by the Common Council of the City of New Orleans, That hereafter it shall be unlawful for any person to spit on the floors of public halls, theaters and other places of amusement, and on sidewalks or banquettes.

"*Section 2.*—Be it further ordained, That any person violating the provisions of this ordinance, shall, upon conviction before the Recorder of the District in which the offense has been committed, be fined in a sum not exceeding Five Dollars or imprisoned in the Parish Prison for a term not exceeding ten days or both in the discretion of the Recorder."

Although it is but a short time since the law has been enacted, its good effects are already apparent. Its reference to sidewalks, to which the principal objections were brought, has already given good results, and I hear from every quarter that the sidewalks are already much improved, although thus far no effort has been made to enforce the ordinance. In order to ascertain this from personal observation, I passed along two of our principal thoroughfares in company with a friend a few days ago, and not only were the sidewalks conspicuous in their improvement in this direction, but a distinct line of expectoration could be seen on the street, just outside of the sidewalks, and where it could not soil the feet of pedestrians generally and the skirts of ladies, thus showing the moral influence of the ordinance and also demonstrating the fact that the citizens of New Orleans are as a class a law-abiding people. It exemplifies the words in the letter of Judge Don A. Pardee in which he states, from his observation of a similar ordinance in Atlanta, that, as the law gains publicity, it practically enforces itself, as all good citizens respect the underlying principle.

As it has been suggested that, in view of the opposition which has been brought against the passage of this ordinance, no attempt would be made to enforce it. This point was investigated and it was found that the police have been instructed to arrest violators of the ordinance, using discretion, however, in the case of strangers and visitors.

In concluding the history of this contest for hygienic advancement, I wish to express my appreciation of the uniformly courteous treatment shown me by the editors of the various papers of New Orleans on whom I called during this discussion, and for offering every facility for presenting to the public views in favor of an ordinance to which they were themselves opposed.

Since the Orleans Medical Society has succeeded in procuring for New Orleans this valuable advancement in hygiene, other medical societies and the medical press should encourage similar efforts, so that in the near future not only all the large cities, but every town and village, will feel the benefits of such hygienic regulations.

ON PRIMARY SARCOMA OF THE LIVER; CRITICAL OBSERVATION AND CONTRIBUTION OF TWO NEW CASES.[1]

BY BINDO DE VECCHI, M.D.,
AND
GIUDO GUERRINI, M.D.,
OF BOLOGNA, ITALY.

THE cases of primary sarcoma of the liver reported by writers are so numerous that one may be led to believe that this form of neoplasm has been erroneously reported as difficult to diagnose and that the law of Virchow on the relationship between primary and secondary growths has met with an exception. Hence we believe that a critical review of the cases might be interesting and,

[1] Pathological Institute of the University of Bologna (Italy).

after closely examining forty-five, we have convinced ourselves that the majority of them should be excluded from the list of primary tumors. It is impossible in this short résumé to give in every case all the reasons which led us to make this exclusion and we refer to the original article for particulars.

Ten cases which are reported probably are not sarcoma, *viz.*, the cases of Naunyn, Lancereaux, West, Roberts, Lee, Pepper, Koltmann, Tooth, Hall, White, Maisenbach and Henschen. The case of Naunyn probably is one of proliferation of Glisson's capsule; that of Lancereaux one of fibroma; West's case is very doubtful, and Roberts' probably a fungous nematode; the cases of Lee, Pepper, Koltmann and White are carcinomata; Tooth's case is a leucemic or a tuberculous lesion, Maisenbach's a myxoma and Henschen's a cystic telangiectatic carcinoma. Seven other cases must probably be excluded also, *viz.*, those of Frehrichs, Wagner, Block, Ledue, Pellacani, Parker and Burnett, since sarcomatous nodules were found in other parts of the body, to-wit, in the skin, intestines, eyes, spinal cord, etc. Eight further cases (Warren, Warshawski, Hutyra, McKee, Axtell, Knoch, Krasnobajew) we have not been able to investigate thoroughly; probably some of these would also have to be excluded. The following table shows at a glance the result of our investigation.

Cases of Undoubted Sarcoma of the Liver.	Cases of Doubtful Diagnosis.	Cases Not Examined.
Hoerup.	West.	Warren.
Podrowzek.	Frehrichs.	Warshawski.
Rehn.	Wagner.	Hutyra.
Pintray.	Naunyn.	McKee.
Lancereaux.	Roberts.	Axtell.
Maffucci.	Lee.	Knoch.
Windroth.	Pepper.	Krasnobajew.
Delepine.	Koltmann.	
Arnold (2 cases).	Block.	
Walch.	Ledue.	
Byrom.	Pellacani.	
Hohlden.	Parker.	
Cesar Demel.	Messenbach.	
Pepere (4 cases).	Tooth.	
Dionisi (2 cases).	Burnett.	
Steinhaus.	White.	
	Henschen.	
	Israël.	
	Kummel.	
	Ruyter.	

Two cases of primary sarcoma of the liver have fallen under our observation, the autopsy notes of which are appended.

Case I.—Man, fifty-eight years old. Slight senile atrophy of the cerebral convolutions and hydrops of the ventricles, pericarditis adhesiva, myocarditis degenerativa, ludocarditis parietalis chromia, atheroma aortæ, emphysema pulmonum, pleuritis adhesiva progressiva, perisplenitis with slight chronic changes in the spleen, nephritis chronica, enteritis follicularis, neoplasma hepatis, cystitis chronica.

The microscopical examination of the tumor showed the presence of a great number of cells. Many of these were elongated and spindle-shaped with a vesicular nucleus; some were large and round and other still larger, with numerous nuclear figures. In the nuclei of the cells it was possible to observe numerous signs of cellular division of the type of either regular or irregular karyokinesis (mitosis pleuripartea, anomalous disposition of the chromatic loops, hyperchromatosis, etc.). This was particularly seen in the giant cells. In several places the protoplasm of the cells showed an evident homogeneous appearance. In other parts the nuclear substance did not readily take up aniline dyes. The vessels of the tumor were few in number, of defective walls and empty, but in a few places there was evidence of hemorrhage. We have made the diagnosis of sarcoma magnicellulatum polymorphum.

Case II.—Man sixty-six years of age. Rachileptomeningitis chronica, edema cerebralis, endocarditis chronica, myocarditis degenerativa, pleuritis adherens progressiva, anemia, edema et emphysema pulmonum, anemia renis, slight gastro-enteritis catarrhalis, perihepatitis chronica, neoplasma et cirrhosis hepatis.

Pieces of the tumor were examined by different methods with the following results: It consists of accumulations of small, fixed cells with, especially toward the center, larger cells with vesicular nucleus, granular protoplasm and droplets of fat. Signs of necrosis and mononuclear giant cells are rather abundant. The smaller cells sometimes appear in singular masses contained in a sort of capsule consisting of fibrillar connective tissue and permeating in numerous layers the entire tumor. In some places it is sharply outlined; in others it furnishes support to the small cells and by a series of sections the connection between cell and stroma is clearly demonstrated. We thus have, in short, regenerative features in the form of cellular division of normal or abnormal type, and degenerative signs as necrosis, cloudy or fatty degeneration of the cells, morphological or chemical destruction of the nuclei. In addition droplets of fat are seen accumulated between the fibrillar tissue often appearing like rosaries. Surrounding the areas of necrosis, giant cells are numerous which is probably a sign of reaction on the part of the organism. The vessels are also very numerous, of defective walls, but filled with blood. In places the tumor in fact appears like a cavernous angiosarcoma. Near the vessels and elsewhere are signs of hemorrhage which often are old, since only represented in the tissue or bodies of the leucocytes by pigment which gives the iron reaction (Stieda's method). Apparently normal islands of liver-tissue are also encountered, demonstrating the strong resistance of the organ to the invading process. The microscopical structure of the liver external to the tumor proper is also very interesting. The pericellular spaces are found enlarged; the cells are spindle-shaped or crushed and their protoplasm is granular and filled with a large quantity of pigment and fat. The connective tissue is increased, forming massive layers which invade

the acini; it consists of fibrillæ interspersed among which are fat-globules and pericellular elements and in places biliary vessels, with their epithelial cell, may be found, as well as heaps of tumo cells. Between the latter and the fibrillæ a close connection can be traced which is an important fact in the pathogenesis of primary sarcoma.

The first author who gave an opinion as to the latter point was Arnold. He considered two possibilities, *viz.*, proliferation from the connective tissue of the vessels or of the acini. Delepine admits a proliferation of the cellular elements of the vessels by the irritating action of the substances elaborated by the metabolic activity of the hepatic cells. Byrom regards the tumors as starting from the perilymphatic connective tissue while Kahlden looks upon the tissues around the vessels as the origin. Cesar Demel thinks the growth begins in the normal connective tissue of the liver. Since in our cases the liver was evidently cirrhotic, we are persuaded of another opinion and consider the neoplastic tendency to be attributable to a preceding cirrhosis. The full reasons we have given in our original communication.

NOTE UPON A CASE OF PRETENDED EXPECTORATION OF MYRIAPODS.[1]

BY ALLEN J. SMITH, M.D.,
OF GALVESTON, TEXAS;
AND
R. R. CURTIS, M.D.,
OF ROGERS, TEXAS.

IN November of 1900, Dr. Curtis sent to the Pathological Laboratory three myriapods which he had obtained from a young woman under his care, who asserted that she had expectorated them together with a number of others after violent fits of coughing. The patient was a young woman of highly-nervous type, and was from time to time, especially after exertion and at her menstrual periods, subject to rather severe attacks, which were regarded by her physician as hysterical. In these attacks she was apparently in a semi-conscious condition and complained especially of severe general headaches; such attacks were not accompanied by any elevation of temperature, nor were there any circulatory or respiratory symptoms. Her menstrual periods were somewhat irregular and attended with considerable abdominal pain, but the flow was about normal in quantity, character and duration.

About two weeks before Dr. Curtis received the myriapods, a member of the patient's family came to him with the statement that the girl had had several severe attacks of coughing in which she had coughed up some worms; and he, taking it for granted that the specimens were ascarides, sent her santonine with the usual instructions for preparation and subsequent purgation. In a few days he was notified that she continued to cough up worms, and as the description of the worms seemed unusual he asked for specimens; and several days later received three myriapods which were sent to the Pathological Laboratory for identification. In all a large number were said to have been expectorated, always after severe coughing; thus in five days she was said to have coughed up forty-five specimens of five different kinds.

Dr. Curtis never saw the girl in any of her paroxysms of coughing, and on close questioning found that, except in the case of the mother of his patient, there were doubts in the minds of those about as to the reality of the expectoration of the specimens. Of course, the whole story of the actual expectoration of these insects by the woman is a figment and one must wonder at the credulity of the mother, who, even after the physician had indicated the falsity of the occurrence, insisted upon its reality and strongly defended her daughter from the imputation of pretence. It was stated by one observer that invariably in such a paroxysm of coughing the girl would rush from the room, returning to discharge from her mouth the specimens. Evidently such escape from the observation of those about her was for the purpose of obtaining a supply of her pretended parasites.

The specimens examined in the laboratory were all of the same genus and species, *Parajulus impressus*, Say, (*Julus impressus*, Say, *Jour. Acad. Nat. Sci. Phila.*, 103, 1821), two females and one male. They are well-known vegetable eaters, living under the bark of rotten trees and beneath logs and stones.

Suspecting fraudulence in the case, the writers shortly after receiving the specimens examined the intestinal contents of one of them and found numerous easily recognizable fragments of vegetable material, portions of wood-cells and spiral ducts being easily distinguishable, at once setting at rest the claim of a parasitic nature for the insects.

The study of the specimens revealed a close conformity with the characters indicated by Bollman (*Myriapods of North America*, Bollman; *Bull. U. S. Nat. Museum*, No. 46, 1893), excepting that the females were slightly above his measurements, and that in both sexes the writers were unable to distinguish the dark spots described as partly concealed by the feet. Length, 32 mm. for male, 35 mm. for each female; width, 1.8 mm. for male, 2.2 mm. for each female. Chestnut brown color, with black median line and lateral row of dark dots; each segment above showing two pale lines; the line between the eyes distinct and dark. Specimens slender, not pilose nor smooth. Vertex shows median sulcus; setigerous foveolæ present. Antennæ slender, six-jointed, second largest, rather pilose. Eyes distinct, triangular in shape, the sides of the triangle curved; ocelli 45 (?), in nine rows. Segments 49-55; first segment distinctly striate, others less distinctly so. First segment large, subquadrate, sides broad. Last

[1] From Pathological Laboratory, University of Texas, 1901, No. 6.

segment produced into a short, thick spine, not projecting beyond the anal valves, sparsely pilose. Anal valves smooth, sparsely pilose, faintly marginate. Anal scale obtusely triangular, sparsely pilose. Repugnatorial pore small, round, partly concealed by transverse suture, which is emarginate, situated on posterior part of segment, commencing in sixth segment. Third segment without feet. Pairs of feet, 80-85, equaling the width of the body, moderately pilose; second pair small, with coxæ united into a long parallel appendage. First pair of feet of male large, six-jointed, with numerous tubercles on inner surface, moderately pilose. Genitals exposed, three pieces; the first long, thickly clavate, twisted, pilose; the second long, curved, tubular, smooth, slender; the third curved and bifid at end. Labrum tridentate; maxillary combs, nine in number.

In the above generic and specific description the writers have followed Bollman, modifying their descriptions as their personal observations of the above specimens demand.

MEDICAL PROGRESS.

Night-Sweats of Phthisis.—An efficient remedy, of simple administration and free from unpleasant or harmful after-effects is still to be desired. KARL DORN (*Deut. med. Woch.*, Oct. 24, 1901) has used with considerable success a soap, preferably of linseed or olive oil, containing ten per cent. of formalin in solution. For children a five-per-cent. preparation is better, because less irritating. The procedure is as follows: The body is smeared with the soap and then a brisk general massage is instituted, lasting for five minutes or more. The resulting lather is then sponged off and the skin thoroughly dried. This treatment is very refreshing to the patient and its constitutional effects can soon be noted in the improvement of appetite and the general condition. Care must be exercised in avoiding all mucous surfaces when applying the soap.

Carbonate of Creosote in Pneumonia.—During the past year several very favorable reports have been given in regard to the use of this drug in lobar pneumonia. L. WEBER (*Med. Rec.*, Nov. 2, 1901) adds to the literature on the subject his hearty approval of its use, believing that it must have a specific action upon the toxin, for its full use causes changes in the condition of the patient resembling closely those which appear at the time of crisis. The drug is given in doses of eight or ten grains five or six times per day and usually when a dram or more has been taken the temperature will rapidly fall to normal and the alarming symptoms will disappear. If the drug is then discontinued the temperature again rises, subsiding, however, if the creosote is once more resumed. The beneficial influence does not seem to be due to the bactericidal or the antipyretic effects of the drug, for, so far as experience has thus far shown, the improvement in symptoms is never accompanied by depression or disturbances in the gastro-intestinal tract. A more general test of the value of this drug is hoped for during the coming pneumonia season.

Cytodiagnosis of Urines in Pathological Kidney Conditions.—The diganosis of pathological kidney conditions by the observation of various varieties of leucocytes present in the urine is of recent origin. By the observation of certain precautions in technic one is able to obtain these cellular elements which emanate from the kidney. M. G. MILIAN (*Comptes Soc. Biol.*, Oct. 18, 1901) has studied many forms of kidney lesion from this point of view. In hematuria of tuberculous renal origin there is present a large number of mononuclears and lymphocytes, but only a few polynuclear elements. Pigmented cylinders are also present. In hematuria from epithelioma of the kidney no leucocytes are present. The hematuria of infectious nephritis accompanied by the elimination of microbes in the urine shows the presence of large numbers of polynuclear leucocytes. Cardiac albuminuria is not accompanied in aseptic cases by such cellular elimination. Febrile albuminurias may be divided in this respect into two classes: (1) those which show leucocyte elimination, (2) those which do not. Among the first are the albuminurias accompanying acute articular rheumatism and diphtheria. In the second class those complicating typhoid fever and pneumonia are found. It is not probable that in all cases of any given renal trouble the cytology of the urine is the same, but it is believed that specific similarities occur which can be utilized for diagnostic purposes within certain limits.

Causes of Bleeding during Pregnancy.—The diagnosis of early pregnancy is frequently very difficult on account of the regular or irregular flow of blood from the genital tract. It is possible for a woman to have apparently regular menstrual periods during her entire pregnancy and at delivery nothing abnormal found in the uterus. Diagnosis must here be made upon other signs of pregnancy. The usual causes of uterine bleeding during pregnancy (care always being taken to exclude the urethra, rectum and vagina) are, according to E. A. LAWRENCE (*Bristol Med. Chirurg. Jour.*, Oct., 1901), the presence of fibroids and pregnancy, a granular condition of the cervix, malignant disease of cervix or vagina, threatened abortion of an intra-uterine pregnancy and extra-uterine pregnancy. A granular condition of the os and cervix can be seen through a speculum and can be cured by freely scarifying the granular surface and applying strong nitric acid. When malignant disease is diagnosed the termination of pregnancy and operation are indicated. The difficult diagnosis really lies in distinguishing intra-uterine from extra-uterine pregnancy, although typical cases are, of course, easily recognizable. The three chief points in the differential diagnosis of these conditions relate to the history, the pain, and the bleeding.

The history is of little importance up to the time of bleeding, but the history of sharp knife-like pains followed by more or less shock is very important. Bleeding from the uterus is more profuse in intra-uterine pregnancy, and a profuse and continuous uterine bleeding would almost always negative extra-uterine pregnancy pure and simple. A woman may abort, however, with very little loss of blood and these cases are sometimes mistaken for extra-uterine pregnancy. Again, in extra-uterine cases, a deciduous membrane may be passed and an intra-uterine pregnancy diagnosed. Pain, as a rule, is more severe in extra-uterine cases and accompanied with more or less shock. A concealed intra-uterine hemorrhage may, however, cause considerable pain. The uterus enlarges, but not so fast in extra-uterine pregnancy as in intra-uterine, and the presence of a boggy mass in the cul-de-sac or either fornix is important in arriving at a diagnosis.

Sinus Phlebitis and Thrombosis.—So far as the ear is concerned, J. E. SHEPPARD (*Brooklyn Med. Jour.*, Nov., 1901) finds disease of the mastoid and middle-ear suppuration more often chronic than acute as the cause of lateral sinus affections. Softened by inflammation, the lining membranes swarm with germs, and these, becoming transmitted to the endothelium of the sinus, cause inflammation, desquamation and thrombosis. The deposit of fibrin may be on one side only or across the whole lumen. The clot breaks down, pus is formed, and is carried into the circulation. Sometimes an abscess forms outside the sinus without affecting the blood. Complications are basic leptomeningitis, extradural abscess and cerebral and cerebellar abscess. Rarely the clot becomes absorbed or organized without further symptoms, occasionally the pus escapes through a fistula in the diseased bone. The symptoms are of four groups, (1) due to mastoiditis and otitis media, (2) cerebral symptoms—headache, mostly limited to the affected side and aggravated by pressure over the mastoid; constipation and vomiting are not infrequent; vertigo, restlessness, hyperesthesia, and paralyses are not common and depend on complications; consciousness is usually retained; choked disc and optic neuritis are sometimes seen, but mostly accompany meningitis and abscess; (3) symptoms perceivable externally—edema of the upper part of the posterior cervical triangle, when present is a sign of value, also a circumscribed painful edema about the posterior edge of the mastoid process; a hard, tender, cord-like feeling of the jugular indicates extension of the clot downward, while edema of face and eyelid without exophthalmus means extension to the facial vein; pressure on the nerves at the jugular foramen may cause hoarseness, aphonia, shortness of breath, slow pulse, spasm of sternomastoid, paralysis of the deglutition muscles, or death from respiratory paralysis; (4) pyemia and septic symptoms. The diagnosis is unmistakable when to any acute or chronic ear disease are added rigors with rapidly fluctuating temperature, sweating, localized headache, vomiting, rapidly developing asthenia, and especially a tender cord-like jugular. Generally not all these symptoms are evident, however, and the diagnosis may be only suspected. The treatment is surgical.

Leucocytes in Typhoid.—From a careful study of the blood in forty cases, W. A. WINTER (*Dublin Jour. of Med. Sci.*, Oct., 1901) concludes that the number of red corpuscles gradually diminishes as the fever progresses, but with convalescence regeneration sets in. The number of leucocytes is diminished in nearly all cases throughout the fever. There is progressive lowering in the percentage of polymorphonuclears, an increase of large mononuclears and lymphocytes, and a decrease in eosinophiles. During convalescence the lymphocytes increase markedly, and the eosinophiles reach or even pass the normal number.

Significance of Hoarseness.—Mistakes in diagnosis usually result not so much from the ignorance of the physician as from the rapidity or incompleteness of the examination. So simple a symptom as hoarseness, although usually due to a temporary catarrhal condition, may be the only obtainable indication of a very serious lesion. P. W. WILLIAMS (*Bristol Med.-Chirurg. Jour.*, Oct., 1901) asserts that hoarseness which commences or persists without adequate and obvious cause should never fail to receive careful consideration, including an inspection of the layrnx. A pronounced anemic condition of the fauces and larynx is highly suspicious of beginning local tuberculosis and should lead to a thorough general examination. A cancerous growth may cause hoarseness and give no other symptoms whatever. Pain is not necessarily an accompaniment of this lesion and in fact does not usually appear till the growth becomes so large that successful removal is difficult. Peripheral paralysis of the recurrent laryngeal nerve fibers either before or after leaving the vagus is one of the commonest causes of hoarseness and is usually due to growths or tumors pressing upon the nerve in its course through the neck or thorax. Enlarged glands, goiter, cancer of esophagus and mediastinal tumors may be mentioned, but the most frequent cause is aneurism of the arch of the aorta and this may be the only recognizable sign of this grave lesion.

Action of Peptone on Stomach Motility.—The action of solutions of peptone on the movements and evacuation of the stomach is interesting in its application to the artificial evacuation of this organ by the pylorus without the production of emesis and the attending discomfort. It was formerly held that the ingestion of peptone produced active motivity of this organ with the prompt evacuation of its contents into the duodenum. JEAN-CH. ROUX (*Comptes Soc. Biol.*, Oct. 11, 1901) by experimental observations has disproven this view. He administered to patients 100 cc. of oil and immediately afterward

gave 2 grams of peptone in solution. In one case after twenty minutes the stomach was evacuated by means of a stomach pump and 60 c.c. of oil obtained. In another case 50 c.c. of oil were obtained after 45 minutes. It seems, therefore, that although the evacuation of the stomach is accelerated by the ingestion of peptone, yet it is far from being completed at the end of 45 minutes. Thus peptone seems to be a motor excitant of the stomach, accelerating the evacuation of its contents by the pylorus. Such evacuation is, however, not made in bulk, but slowly and progressively.

Granular Casts.—These casts are characteristic of epithelial nephritis, and are considered by M. PÉHU (*Bull. de l'acad. de méd.*, Oct. 15, 1901) to have prognostic value. In the acute stage, they are numerous, narrow, coherent, with compact granulations, and indicate an active cellular change. In the subacute, they are fewer, of larger diameter, and are accompanied by more hyaline casts. In the chronic stage, while the albuminuria persists, the casts become few, indicating the formation of a true renal cicatrix. An exacerbation is shown by the reappearance of numerous casts.

Gonorrheal Ophthalmia.—As soon as he sees a case, whether in the first twenty-four hours or later, JACKSON (*Intercolonial Med. Jour.*, July 20, 1901) gives an anesthetic and divides all the tisues at the external canthus right down to the bone. This renders useless the orbicularis muscle, and leaves the lids flaccid and free. The advantages are (1) freedom from blepharospasm and from pressure on the globe and rest to the lids; (2) ability to evert the lids completely and thoroughly to apply remedies and to examine the cornea thoroughly; (3) free bleeding from the congested tissues. After the operation he applies a twenty-grain solution of nitrate of silver, and on the following days a ten-grain solution. By a special nurse the eye is washed out every half to one hour with 1 to 6,000 bichloride of mercury, and a stream of weaker solution is kept running over the lids.

Pathology of Diabetes.—Diabetes, like not a few other obscure conditions, has received such brilliant illumination within the past few years through experimental research that our knowledge with respect to it has grown with great rapidity. SIMON FLEXNER (*Pro. Phila. Path. Soc.*, Oct., 1901) comprehensively considers the subject. The pancreas influences and regulates carbohydrate metabolism, but the cause of diabetes is by no means always resident within this organ. Complete extirpation of the pancreas causes in the dog a diabetes of a severe grade, the elimination of sugar by the urine reaching 10 per cent. or more. The acme of the secretion of sugar is reached from carbohydrate food, but a pure albuminous diet does not reduce the amount below 5 or 6 per cent. The amount of sugar present in the blood is increased. Hyperglycemia goes hand in hand with the glycosuria. No organ except the pancreas can act vicariously in regulating the carbohydrate metabolism of the body. That the pancreas in human beings shows marked pathological changes in cases of diabetes is shown by numerous observation. Of the causes of these changes the chief is supplied by concrements in the ducts. The failure of the functionings of this organ in man as a diabetic cause is independent of its digestive functions and probably depends upon an internal secretion supplied by it to the blood. There exists a close relation between the pancreas and liver with respect to sugar production, and it seems probable that the pancreas regulates through the nervous system the production of sugar by the liver. Although the proof of the hepatic origin of diabetes is inconclusive, it seems sure that in some cases diabetes results from disease of the liver, the pancreas remaining normal. Pathological conditions of the central nervous system and probably of the sympathetic and larger peripheral nerves may give rise to diabetes, but the relationship between such and the organs of carbohydrate metabolism is unknown. The existence of a renal form of diabetes is unproven, although the production of experimental phloridzin diabetes shows that the kidneys are not merely passively engaged in the elimination of the urinary constituents. It seems certain that the symptom-complex of diabetes is dependent upon no one set of functional and anatomical conditions.

Gastric Ulcer.—In the anatomical study of gastric ulcer (Prize thesis, *Bull. de l'acad. de méd.*, Oct. 15, 1901), the author establishes the following conclusions: (1) There exist several different types of lesion (ecchymosis, infarct, hemorrhagic erosions, cicatrices, superficial ulceration of the mucosa, etc.), which may be considered as initial alterations, in some way preparatory for the development of an ulcer; (2) the process which creates the loss of substance, where the ulcer is an acute process; (3) such simple ulcers are not confined to the esophagus, stomach and duodenum, but are found throughout the whole length of the intestine, in the bladder, the vagina, and possibly in the gall-bladder. These extra-stomachal ulcers indicate that the gastric juice and auto-digestion are not necessary for the production of ulcers of this type. That an important causative factor is a toxemia is indicated by the relative frequency of ulcer in alcoholism, lead-poisoning, chlorosis, gout, diabetes, renal and hepatic toxemias, infectious diseases, burns with large space for absorption, etc.

Midwifery.—The lateral position is best for all purposes and is preferred in forceps cases by R. E. MCKECHNIE (*Dominion Med. Monthly*, Oct., 1901) because it is easier to pull in the axis of the brim than when the dorsal position is used. He grasps the forceps with the left hand, the ulnar side toward the vulva, and with the wrist against the buttock as a fulcrum uses the arm as a lever. This gives great force and prevents the patient being pulled about. If the forceps slip, the power of the lever is lost until the fulcrum is readjusted, so the slip cannot be great.

As the blades pass inside the membranes, not touching the uterine walls, the author seldom follows by douching. In the case of twins, there is no need to wait for the second one, for the canal is fuly dilated, and no harm results from rapid extraction. Ergot should be used more frequently, as it helps the pains; if it causes tetanic contraction, it can be absolutely controlled by chloroform. Commonly with the use of chloroform increased hemorrhage may be looked for, as it lessens the contraction of the uterus. Therefore it is good practice to give a dose of ergot before beginning chloroform, so that the ergot may be ready to work as soon as the chloroform is done. Calcium chloride in dose of gram 0.35-0.7 (gr. v-x), three times a day, during the last month, will increase the coagulability of the blood. To avoid the necessity of catheterization, the author has the patient turn over on her stomach, then get up on her hands and knees, taking care not to assume the erect position. Micturition is then usually easy. He has never observed any ill-effect from this procedure, and considers that a retroversion or prolapse is quite unlikely in the first few days on account of the size of the uterus.

General Metabolism in Diabetes.—The fact that progressive emaciation and excessive nitrogen excretion are characteristic symptoms of diabetes has given rise to the view that there is some essential factor in this disease which causes abnormal activity of tissue destruction, and that the excess in nitrogen excretion is evidence of excessively active protein metabolism. It was formerly held that the essential feature of this disease is azoturia and that the nitrogen excretion regularly exceeds the intake. It is now known, however, that the loss in fat and nitrogenous tissues is, in ordinary cases, purely secondary due to the fact that the large amounts of food taken in are in great measure excreted practically unchanged. Thus the constant demands for energy require the excessive breaking down of the body proteids and fats. It is now known that the primary nutritional difficulty in diabetes relates solely to carbohydrate metabolism. This is shown in the storage of glycogen and the quantities of sugar in the blood and urine. Glycogen is reduced in amount and may almost entirely disappear from the liver. Diabetic coma is due to a form of intense acid intoxication not due to any special toxic agent, but to the mere excess of fatty acids which flood the blood. The substance which is undoubtedly chiefly active is oxybutyric acid. The main theories concerning the definite nature of the disturbance of metabolism are as follows: (1) That it is due to the over production of sugar; (2) that it is due to the imperfect oxidation of sugar and its consequent accumulation; (3) that it is due to insufficiency in the production of glycogen, so that sugars absorbed from the digestive tract or formed in the body constantly reach the circulation and the excess instead of being stored is steadily excreted. The first theory at present deserves but little consideration. The last, although based upon inconclusive grounds, has many facts to support it. The general tendency is to put faith in the theory of the imperfect oxidation of sugars supported by the fact that in diabetes the respiratory quotient is low. This subject has received exhaustive consideration by D. L. EDSALL (*Pro. Phila. Path. Soc.*, Oct., 1901).

Functions of Basal Ganglia.—Of three cases of insanity dying in the State sanitarium of Georgia, autopsies showed pathological conditions which seemed of value in determining the functions of certain parts of the brain. In one, the posterior two-thirds of the lenticular nucleus and the posterior half of the caudate nucleus were the sites of marked softening, the remainder of the brain remaining normal. In a case of general dementia the patient was suddenly seized with clonic contractions of the left side and complete loss of consciousness which continued for twenty-five minutes, when he died. The only pathological lesions found were two small hemorrhages in the optic thalamus of the right side, one being about the size of a pea. A case of chronic mania died of a severe enteritis and autopsy showed a large cystic tumor of pineal gland whose normal tissue had entirely disappeared. M. L. PERRY (*Med. Rec.*, Nov. 2, 1901), who reports these cases, concludes that the corpus striatum has no intimate relation with the motor or psychical spheres, and that a large destructive lesion of these nuclei may produce no symptoms; also that there is an area in posterior part of optic thalamus, irritation of which will produce unconsciousness and contraction of muscles of opposite side of body.

Obstetrics.—In eclampsia it is useless to wait as regards emptying the uterus, and, after seven months, GEORGE M. MCCOMBS (*Albany Med. Annals*, Nov., 1901) rapidly dilates under chloroform and extracts with forceps. Thus he saves the child. The mother he treats with blood-letting and saline solution, combating symptoms as they arise. For hemorrhage from placenta previa, he would probably pack until ready to operate quickly, then remove the packing, dilate and extract by version or forceps. Postpartum hemorrhage is always serious, and its correct treatment is by packing. After the birth he uses a small damp bichloride compress over the vulva covered by the regular napkin. This protects the entrance to the vagina, which is the abode of germs. He never uses the douche, as it washes away the natural germicidal secretions of the vagina. He uses chloroform guardedly and always gives ergot as the head is born; he then waits half an hour and finds that the placenta seldom adheres after this time. The curette is more opposed to aseptic surgery than is the douche, for it opens up new avenues of infection. As "dryness is an enemy of bacteria," he treats a septic uterus by wiping it out, and packing with dry sterile gauze, renewing it every eight to twelve hours. When the woman gets about he applies the abdominal bandage with a T-

bandage and pad support to the vulva, and prescribes a tonic of strychnine. He prefers to move the bowels with Rochelle salt or Seidlitz powder, rather than with castor oil. The cord he cuts short and wraps in sterile gauze, then applies a four-inch gauze bandage several times around the abdomen and keeps it on a week.

Malarial Hemoglobinuria.—The symptoms of malarial hemoglobinuria are described by O. LERCH (*New Orleans Med. and Surg. Jour.*, Nov., 1901) as follows: The attack begins with a severe and protracted chill and soon after the characteristic urine, containing albumin, hemoglobin, hyaline and granular casts, and renal epithelium is voided. The cachectic appearance changes to a deep jaundice and excruciating headache and backache, severe pain in the epigastrium and extremities, flushed face with injected conjunctivæ, copious vomiting of greenish liquid which may become black, great mental anxiety, profuse, cold, clammy perspiration, biliary diarrhea, high temperature and small, frequent pulse develop. The estivo-autumnal parasite is always at fault and the patient generally has had repeated attacks of fever, but climate and a certain individual predisposition are also active causes in setting up the hemoglobinuria. Several varieties of this must be considered; thus in some cases the attack will appear with the sporulation of the parasite; in another, the post-malarial, all the parasites have disappeared from the blood; and, finally, there is the quinine hemoglobinuria, where it appears as if this drug were at fault. The mortality varies from 10 to 50 per cent. Confronted with a case of malarial hemoglobinuria the first question to settle is whether the paroxysm represents merely a symptom of active malaria or whether it is of post-malarial origin. With the microscope this is an easy matter. In the former case quinine must be given, best hypodermatically, whether the drug is followed by blood in the urine or not. In the second set of cases rest, fresh air, oxygen, the cleaning of the emunctory channels and sustaining of the system are necessary.

Oöphorectomy and Thyroid Extract for Mammary Carcinoma.—Five years have now elapsed since this novel form of treatment was first proposed by GEO. THOMAS BEATSON of Glasgow. In a very poignant contribution (*Brit. Med. Jour.*, Oct. 19, 1901), he cites some further conclusions of his own, and histories of cases which have been treated by others. That the results are, as Mr. Watson Cheyne puts it, "very striking," cannot be doubted and it is of particular interest to those who dwell so under the shadow of the parasitic theory to note that the facts gathered from the procedure of Beatson seem to bear strongly against the views advocated by Dr. Park. The dose of thyroid extract can vary according to the case from 15 to 250 grains. In closing, the writer very modestly asked whether it seemed too early to advocate the employment of his form of treatment on other than inoperable carcinomata. Again, in view of the great success which had crowned its employment in apparently hopeless cases, was it not debatable whether, in the early varieties, it should be used in conjunction with the ordinary operation, or in place of it.

Complications of Obstetric Practice.—The treatment of various complications occurring during delivery and the puerperium is given by J. W. D. HOOPER (*Internat. Med. Jour.*, Oct., 1901), who insists on strict cleanliness throughout as the chief preventive of septic complications. Uterine douches should never be given unless the hand has been placed in the uterus or the presence of hemorrhage demands it. Curettage is seldom indicated and should not be performed unless, after three days have elapsed, there is an odor to the lochia, pain over the fundus, fever with or without chills and during the third stage of labor there had been signs leading one to believe that some membranes or a piece of the placenta had been left behind. If a postpartum hemorrhage occurs in a woman with relaxed uterine muscles, the treatment consists of massage of the fundus, followed if necessary by a uterine douche of sterile water, bichloride, 1:5000, lysol, ½ per cent., or acetic acid, 4 per cent., at a temperature of 120° F. If these means fail the uterine cavity and vagina must be firmly packed with sterile gauze. After a severe hemorrhage salines or an infusion are of great assistance to the patient in regaining the blood-supply.

Symptomatology of Apoplexy.—Since such a large percentage of all people over fifty years of age die of apoplexy, it is important to appreciate as early as possible any tendency toward that condition and especially any warning signal which may be had of impending danger. T. DILLER (*Med. Rec.*, Nov. 9, 1901) emphasizes the fact that apoplexy may occur without the production of either of the ordinary symptoms, paralysis or loss of consciousness, and the recognition of such an apoplexy is extremely important for it enables most valuable treatment to be instituted. Sometimes there is only a temporary cloudiness of the mind or with this there may be more or less disturbance of vision or even hemianopsia. Apoplexy of the retinal vessels is not an infrequent precursor of apoplexy of a cerebral vessel. Paralysis of a group of muscles or a hemiplegia may be present without any disturbance in consciousness and, on the other hand, complete loss of consciousness or even coma and death may appear without any paralysis. An apoplexy with softening may cause such mental disturbance that cerebral tumor may be diagnosed. In one case the symptoms which appeared, being common to both lesions, were headache, nausea, vomiting, vertigo and stupor. Cerebral softening may also cause a train of symptoms very closely simulating hysteria and several cases have been treated as such by eminent physicians. Furthermore, edema of the brain or abscess may be mistaken for apoplexy, on account of the similarity of

symptoms. It is therefore important that obscure cerebral conditions occurring in persons, especially when past mid-life, should arouse the suspicion of an apoplectic lesion resulting from arterial changes.

The New Surgery of Renal Calculus.—A British joker recently said, in speaking on the effect of the use of X-ray in renal surgery, "The policy of pin-pricks becomes needle-less." A verification of this jest is the goal of a paper by J. HUTCHINSON, Jr., (*Brit. Med. Jour.*, Oct. 19, 1901). It is axiomatic of renal and vesical surgery that the smaller the stone the greater the suffering, and *vice versa*. Hence, the minor value of pain as a factor in deciding for or against an operation, and the import of the rays, which, under proper management, can now be depended on for diagnosis in all cases, even in the absence of characteristic symptoms. It is true that in very fat subjects it is as yet difficult to get a good shadow; but patients suffering from renal calculus do not usually retain their fat. Except in extraordinary cases even this objection fails when the stone is either phosphatic or oxalic, since these calculi cast a shadow much more dense than those of uric acid. A reduction of the exposure to fifteen seconds has done away with the difficulty which arose from the respiratory excursions of the kidney, for during that period the patient can hold his breath. In conclusion it may be stated that (1) the X-rays give a positive diagnosis as to size, position and number of calculi; (2) they make possible nephrolithotomy with least possible injury to the organ and without bringing the organ to the wound's surface; (3) calculi should be removed through the renal pelvis whenever possible; this is contrary to the usual teaching, but such wounds heal better than those of the parenchyma; (4) before and after operating, the use of urotropin and salol is of great value; (5) calculi, however small, should be removed as soon as diagnosed; their danger bears no relation to their size.

Etiology of Apoplexies.—Since "a man is as old as his arteries," Osler says that longevity is thus made a vascular question and that to a majority of men death comes primarily or secondarily by this portal. Poor quality of arterial tubing may be inherited, but the influence of various poisons and the stress of life are undoubtedly most potent factors in determining arterial degeneration. Syphilis and alcohol have long been considered as important agents. W. K. WALKER (*Med. Rec.*, Nov. 9, 1901), points out that high functional activity frequently determines the location of the lesion, citing the instance of a hemianopsia occurring in a priest with unusually arduous labors, who was also an artist spending all possible time with his brush. Again, certain poisons seem to have a selective power, syphilis, for example, so frequently affecting the visual centers and the muscular mechanism of the eye. Recently, the belief that toxemias of gastro-intestinal origin are potent factors in producing vascular degenerative changes has been suggested and does not seem at all improbable in the light of recent discoveries in neuropathology. Appreciation of the far-reaching and destructive influences of the various poisons upon the blood-vessels, as well as upon the nerve-cells, brings practical results. Perhaps in no other class of cases is the influence of heredity more easily traced than in those due to vascular changes. It is not, however, a disease which is here inherited, but "a peculiar type of tissue, which renders the individual peculiarly susceptible to the influence of morbific agents."

Vaccination During Pregnancy and the Puerperium, and in the New-Born.—The results of vaccination in over a hundred cases belonging to these groups are stated by H. PALM (*Fortschritte d. Med.*, Oct. 15, 1901). Vaccination during the last four months of pregnancy was entirely successful, producing no troublesome phenomenon whatever. In view of the tendency of variola to run an especially severe course in pregnant women, the latter should receive prompt vaccination or re-vaccination whenever exposed to smallpox. Palm found that he could successfully vaccinate new-born infants of mothers vaccinated during the latter months of gestation; the fetus apparently is not protected by the vaccination of the mother. Vaccination is declared to be absolutely without danger during the first week or even the first day after birth. Even prematurely-born infants will bear vaccinationtion well and should be vaccinated in the presence of a smallpox epidemic.

Treatment of Acute Lobar Pneumonia.—Venesection gives such immense relief to the right heart and the pulmonic congestion in lobar pneumonia that J. N. HALL (*Phila. Med. Jour.*, Nov. 9, 1901) believes it should be oftener employed. Seriously embarrassed circulation is the indication for venesection. In a large series of cases ice-bags were applied to the chest with benefit. This writer uses turpentine stupes and sinapisms, and later a cotton jacket with camphorated oil. For sleeplessness as well as for painful cough Dover's powder with hot whisky were used with good results; an opiate is preferred to more depressing hypnotics. In complicating pleurisy a hypodermic injection of morphine was followed by a reduction in the frequency of the painful respirations from fifty to thirty per minute. The free use of strychnine is recommended in cardiac distress; it may be given hypodermically if circulatory depression is marked. In cases of hard, bounding pulse with flushed face liq. ammoniæ acetatis or the sweet spirits of niter gave as much satisfaction as either aconite or veratrum. During the height of the fever ½-ounce doses of infusion of digitalis every two hours frequently failed to lower the pulse-rate, but with a fall of temperature the slowing of the pulse was notable. In a few cases antipneumococcic serum was used, but without any noteworthy or particularly encouraging consequences.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

THE MANUFACTURE OF SERUMS.

IN a previous issue of the MEDICAL NEWS we gave an authentic and full account of the accidental inoculation and death of several patients from tetanus contaminated antitoxin in the city of St. Louis. We then reported that the horse from which the antitoxin had been taken had acquired tetanus in some unknown manner, although subsequent investigations have shown great carelessness in the care of the stables in which the horses were kept. The symptoms, however, became recognizable, only after a certain quantity of the antitoxin had been placed on the market by the local health department, in whose hands the manufacture of the serum was vested.

Closely following this lamentable accident steps were taken in several cities to guard against similar misfortunes, and in the *Echoes and News* columns of last week's issue we published some of the resolutions adopted by several societies.

This calamity opens an interesting and at the same time an extremely complicated series of medical, legal, ethical and social problems, involving questions of protection of the community from disease, of responsibility for accidents of this kind and of the rights of citizens, of physicians and of manufacturers of antitoxins, both civic and lay.

It is impossible for us to more than indicate in this place a few of the relations of these questions. It is of interest, in the first place, to call to mind some of the arguments offered by the representatives of the Tax-Payers' Association of New York City, some two years ago, in their meeting before the Cities Committee bearing on the standing of the State or the City as a manufacturer and seller of antitoxin. It was shown at that time, we believe, that a municipality is not ethically privileged to become a manufacturer and seller in the open market of a commodity which can be prepared by responsible business enterprise at a reasonable and just price.

Without in any sense pandering to the manufacturer of antitoxin or of vaccine, we believe that the evidence warrants the conclusion that any board of health, City or State, is privileged only to manufacture sufficient of these or other like commodities to provide for the sick poor of the community who are a charge upon its charity. To manufacture over and above such quantities and to make sale of the same for private or for civic gain, is, we believe, unjustifiable.

On the other hand, however, it should be borne in mind that the New York City Board of Health was among the first in this country to recognize the value of the newer serumtherapy and that it, with other health departments, made it possible for the community to procure for its suffering citizens remedial agents which no commercial house dared manufacture until the demand was created and the market assured; and, moreover, it is a fact, for New York City at least, that the monies which have been made by the sale of its serum products have enabled it to conduct experiments on a far-seeing plan which have been of inestimable service to science and to humanity. We believe, however, that the means for such experiments should be provided by direct appropriation and that no municipal health department should be reduced to competition with first-class manufacturing houses for the sake of making a little money with which to carry on scientific research. If a city cannot or will not make suitable allowance for such work, we do not wish to see its health department hampered by legal restrictions in the sale of its serum products. We think that the dignified and suitable rôle of the health department is, however, not that of a manufacturer for sale, but that of a controller, regulator and inspector.

An even more vital question is, how can we, as physicians, be guaranteed the highest grade of antitoxin or other serum which may be required in the combat with disease? Which will manufacture the best antitoxin or vaccine, the commercial house or the municipal health department?

Under ideal circumstances equally trustworthy products will be furnished by each, but ideal conditions are rarely found. Commercial greed, on the one hand, will cheapen the product as will political influence in appointments on the other, and of the two we believe that healthy competition of business houses will result in a better controlled product than can be expected from municipal manufacture. Experience in other lines of industry has emphasized this point too strongly to admit of much argument, although, as far as New York City is concerned, its health department has given us the highest class of serums, but the men connected with its laboratories have been exceptionally well qualified for the undertaking. In a shifting political régime, however, it is hardly to be expected that the best will always be appointed, and we have known the time when the New York City Health Department has been an opprobrium rather than an ornament.

A HYGIENIC VICTORY.

Six days did the children of Israel march around the walls of Jericho and blow blasts on their rams' horns; to no avail, but on the seventh day when they blew a blast all together, the walls fell down flat. Whether or not this historical detail hints at a remarkable property of acoustics, it certainly points a civic moral. When the people of any town do anything altogether the walls of prejudice and precedent will fall down flat.

New Orleans has just been going through this experience and has come out triumphant. The experience that Dr. Scheppegrell describes in his paper on "Hygiene and Hygienic Legislation" is an interesting commentary on the necessity for united aggressive persistency in accomplishing any reform.

Our readers would be startled and surprised to listen back a few hundred years and hear the discussions on the laws of decency that agitated our forebears; the plausible reasons they set forth for observing certain proprieties that not even a street gamin would think of violating now; the efforts to put in fashion superfine niceties that are now the commonest necessities of decent habit. Could we review the civic struggle for sewerage, the tussle for pure water, the fight for quarantine of infectious disease it would look as though we had had a hard time growing out of brutedom.

We think that Dr. Scheppegrell's paper would be worth preserving a hundred years, by which time doubtless spitting will have become a private ceremony, and tuberculosis a quarantined disease; and our great-great-grandchildren will read it as a curiosity, and say "To think they could have been so nasty in those days."

THE SIGNIFICANCE OF MINOR SURGERY AND THE RECENT GRADUATE.

Among the many changes of heart and mind which a few years of private practice bring to the medical man, none is perhaps more significant than that which he undergoes in his attitude toward surgery.

Very early in his student career, unless by some unusual chance his mind is turned in the direction of a specialty, he is strongly impressed with the tangibility of matters surgical. He witnesses the skill and intrepidity with which his surgical professors undertake capital operations and soon begins to itch with the desire of emulation. During his period of externe service—if he is fortunate enough to secure a hospital appointment—he consoles himself for the wearying daily round of septic hands, fractured bones, abscesses, etc., to which he is compelled to attend, with visions of the major operations at which he will assist when his out-patient service has come to an end and he has arrived at the dignity of house-officership.

When this happy time has at last come, the goal of his ambition is attained. He spends the ensuing year or more of his interne service in one glorious round of abdominal and other capital operations and is content. And if, perchance, good fortune—in the guise of an emergency—or good nature on the part of his chief permits him to play the leading rôle in the performance of an operation of importance, his happiness is ineffable.

Viewed from this pinnacle of achievement, the old days of his out-patient career dwindle into insignificance. He recalls the multitude of dressings he was compelled to do, the innumerable splints he had to adjust and readjust, and smiles fretfully at the constantly occurring delays in the smooth working of the clinic caused by the stupid reluctance of patients to come forward and have a lancet thrust into an absurd

felon or an insignificant abscess. He wonders how people dare waste the time of a surgeon in hesitating over such trivial matters when so many of—from his point of view—infinitely greater importance are awaiting his attention.

And then he goes out into the world, leaving the shadow and protection of a great hospital, to deal single-handed with humanity. He may not openly avow his attitude, but it is essentially as follows: "Of course, I am willing to repeat my uninteresting experiences of the out-patient department, but it is really only major surgery that appeals to me."

He is, therefore, keenly alert in the small field of work which opens up to him in private practice, for a cantankerous appendix or insinuating neoplasm. He views every pain in the abdomen with the distrust born of surgical experience and palpates every irregularity of contour with nice precision.

Finally, the opportunity to show his manual dexterity presents itself, but, to his extreme disgust, it is not an appendix, not a breast amputation, but a miserable ingrowing toe-nail.

He assures the patient that it is a mere bagatelle, that he will drop in some day, give her "a whiff of ether," slice off the nail and, incidentally, a small portion of the toe. And then—if he is endowed with a fair allowance of common sense—he acquires some information that stands him in the greatest stead during the remainder of his professional career. He learns that in his off-hand proposal to operate on that toe-nail he has unwillingly threatened the peace of mind and started up the antagonism of the patient's entire circle of friends and relatives. And if, by rare good luck, the proposal does not send the patient at once to Dr. X., who "never uses the knife" in such cases, the presumptive operator's troubles are just beginning for him. Grandmother knows the patient has a weak heart and would never stand the ether. Grandfather thinks that a bread-and-raisin poultice would be just as efficacious as any other means of attacking the evil. Mother once had a boil lanced on the back of her neck and it was months before it healed—and she is sure that daughter's flesh is just like hers. Father thinks just as mother does. The ubiquitous "friend of the family" knows a lady who had a similar operation and was just as badly off as ever at the end of a couple of months, etc., etc., *ad infinitum*.

Then the ambitious operator begins to get an inkling of the colossal proportions of the undertaking he has jauntily let himself in for and wonders who invented the absurd term "minor surgery" for operations of this sort. Viewed from the family's standpoint, it comes over him that in comparison with this the average capital operation of the hospital is a matter of trivial significance, and, if he is a wise man, he alters his attitude and views to fit the circumstances.

From this period in his career on the hankering for an appendix to remove or a breast to amputate is not so insistent and overpowering. Of course, if it is really imperative, he is ready to undertake either task, but then, there are so many things to consider—and his experience in private practice with what he used to call "minor surgery" has taught him many things.

BUFFALO AND ITS HEALTH COMMISSIONER.

OUR Buffalo confrères struck the keynote of medical ethics at the meeting of the profession called to express their desire that Dr. Wendé, the Health Commissioner, should be retained under the new administration. As Dr. Pryor said, in addressing the meeting, "It is not so much a question of the office or the man, but the essential thing is the ideal that every true physician is striving for—that ideal is the placing of life and death above the realm of politics."

Dr. Wendé has done magnificent work in the Board of Health. During his term of office the actual death-rate has dropped, despite the increase of population, and, according to the *pro rata* death-rate, Buffalo ranks as the healthiest city of its size in the United States. This is undoubtedly due, according to Dr. Wendé's fellow practitioners, to the non-partisan, scientific, business-like administration of the Health Department, which for the first time in its existence has been taken out of politics.

Newly-elected Mayor Knight, it is confidently reported, does not intend to reappoint Dr. Wendé, whose zealous work has occasionally interfered with politics *per se*, and gossip names as his successor Dr. Green, who has been Dr. Wendé's assistant, and who is a Republican, and a fellow Mason of the new Mayor.

Friendship goes a long way, and Dr. Green would undoubtedly fill the position well; but we feel with the Buffalo physicians that when a scientific man has served his city and humanity as disinterestedly and as ably as Dr. Wendé has done, his genius and the value of his service to the community might well be weighed against party and personal interests.

ECHOES AND NEWS.

NEW YORK.

Dinner to Dr. Thomas.—A dinner was given to Dr. T. Gaillard Thomas at Sherry's, Thursday evening last. It was attended by a large number of New York's representative physicians.

A Tribute to Dr. Thomas M. Markoe.—There was a black-bordered leaflet in the printed bills which commemorated the death, since last season, of one of the oldest of New York's Philharmonic patrons. As told in the leaflet, Dr. Thomas M. Markoe became a subscriber to the concerts of the society upon its organization in 1842 and continued as such during fifty-nine years of its history. His enthusiasm led him to attend the private rehearsals for the early concerts. and he thereafter continued to manifest the same intense interest in its artistic mission. He was a lover of music and an excellent amateur performer, seeking in the enjoyment of this art relaxation from the arduous practice of his chosen profession. The society recorded its tribute to his memory, "recognizing in him a most conspicuous member of that discerning audience, which by its presence and patronage has continuously sustained the society's work and encouraged it with intelligent approbation." The veteran society is not unmindful of its friends.

A Rogue to be Captured.—Pinkerton's National Detective Agency, through its New York office at 57 Broadway, advises us of the operations of a swindler and forger, who is forging the names of physicians in different cities and towns as indorsements to bogus checks passed by him upon banks in which the physician whose name is forged has an account. The swindler's *modus operandi* is as follows: Calling upon physicians he introduces himself as an agent for an association which contracts to supply its members with medical books at from 20 to 30 per cent. less than the regular rate, and solicits a membership fee of $1.00. As an inducement to sign the contract the swindler waives the membership fee, obtaining the signature of the physician solicited, at the same time requesting a bank as reference. In this way the swindler gets his victim's signature and the name of the bank in which he has an account. Several hours later he appears at the bank named with a fraudulent check requesting payment. Upon being refused payment he states that he will have a physician indorse the check (naming the physician who is a depositor and whose signature he had previously obtained in the method described above). The bank officials usually state that such an indorsement will be accepted. The forger then leaves the bank, forges the name of the physician solicited earlier in the day, and on presenting such check again at the bank is usually accommodated with the amount for which it is drawn. He assumes that the average bank would not question a physician's indorsement. This impostor has been quite successful in swindling banks by this method, and has been the cause of much annoyance to physicians whose names have been forged. He, in the past, has used such names as C. J. Merrill, Chas. J. Parsons, John T. Corson, H. A. Mann, D. A. Mason, and more recently in Connecticut he used the name of Henry A. Marling. This swindler is rather a dapper-looking young fellow, 30 years of age, 5 feet 8 inches tall; weighs about 140 pounds; is of slender build; has light complexion, light hair, blue eyes, rather large nose and is usually clean shaven. The Pinkertons seek the coöperation of physicians in the apprehension of this swindler, and suggest that if he calls upon any of our readers they evince no suspicion, but furnish the so-called solicitor with their signature and bank references, but immediately notify the bank where they have their account, advising them of this man's scheme. The local police authorities should at the same time be advised. If the Pinkertons, who are interested for the American Bankers' Association, are communicated with, they will give any information immediate attention.

New York Academy of Medicine.—On Wednesday evening, November 27th, the Section on Laryngology and Rhinology will meet. Dr. Emil Mayer will read a paper on "Affections of the Mouth and Throat in the Adult, Associated with the Fusiform Bacillus and Spirillum of Vincent;" Drs. Jacob Sobel and Charles Herrman will read a paper on "Ulcero-Membranous Lesions of the Tonsils in Children, Associated with the Fusiform Bacillus." Drs. Morris Manges and E. Libman will open the discussion.

On Friday evening, November 29th, the Section on Obstetrics and Gynecology will meet. The following papers will be read: "Etiology of Puerperal Fever," by A. E. Gallant; "Treatment of Puerperal Fever," by R. A. Murray; "Surgical Treatment of Acute Puerperal Sepsis," by H. N. Vineberg. Drs. J. C. Edgar, H. J. Boldt, H. J. Garrigues, S. Marx and others will discuss the papers.

PHILADELPHIA.

Resolutions of the Camden Board of Health.—At a meeting of the Camden Board of Health November 18th, it was decided to allow children to attend school regardless of vaccination and to advise that all vaccination be stopped for the present. This action was taken as a result of the six deaths from tetanus which have lately occurred in vaccination cases. One of the members of the Board stated that during the continuance of the dry weather any scratch or laceration was dangerous. A committee of three was appointed to coöperate with the county authorities in endeavoring to decide positively if the vaccine virus in use has been responsible for any of the cases of tetanus. One of the manufacturing firms has agreed to pay a portion of the expenses of a thorough test of the virus furnished by them and others.

New Ward at St. Timothy's Hospital.—The new Percival Roberts Memorial Ward of St. Timothy's Hospital, Roxborough, was dedicated November 16th. The building was erected by Mrs. Roberts as a memorial to her late husband.

Smallpox.—New cases for the week ending November 16th were 50, the deaths being 12. President Shoemaker of the Department of Charities and Correction has issued an order that while smallpox continues epidemic in the city no visitors will be allowed in the Philadelphia Hospital to see patients. Guards who are maintaining quarantine in the infected districts of the city are erecting booths for shelter during the approaching cold weather. These guards number considerably more than one hundred.

Tetanus Following Vaccination.—The residents of Camden are becoming alarmed over the deaths from tetanus following vaccination and many of them are afraid to submit to the operation. Five deaths have occurred within the last ten days and several other cases have been treated. At least one death has occurred in this city. Physicians have no hesitancy in ascribing the cases to carelessness in caring for the wounds, but it is exceedingly difficult to convince the laity of that fact. It is thought that the unusually dry weather of the past two months has caused the tetanus bacilli to be disseminated through the air to an unusual degree. One fatal case, a boy of seven years, was reported by his physician as having dropped the scab from his arm into the street. The boy replaced the scab and afterward developed tetanus. But one fatal case of smallpox has occurred in Camden.

Quinine Rashes.—Dr. H. C. Wood, Jr., by invitation, read a paper on this subject at a recent meeting of the County Medical Society. He discussed the subject under three heads, diagnosis, predisposing causes, and treatment, and gave a review of the literature on the subject embracing 61 cases. In the diagnosis two points are of especial interest—the involvement of mucous membranes and desquamation. In 14 of the 61 cases reported there was desquamation, and in 11 of the 14 the mucous membranes were involved. These facts bring scarlet fever into the question of diagnosis. The most potent cause is idiosyncrasy, age, sex, size of dose, etc., having little bearing on the production. Treatment is symptomatic. When the idiosyncrasy is known the drug should be given hypodermically. In discussing the paper Dr. Jay F. Schamberg said that the differential diagnosis between scarlet fever and quinine rash should be based on (1) the history of exposure to scarlet fever; (2) the greater intensity of constitutional disturbance in scarlet fever; (3) the desquamation in quinine rash is not so persistent; (4) there is not that peculiar desquamation of the fingers, especially around the nails, in quinine rash; (5) there are not the enlarged tonsils covered by a yellowish exudate, as in scarlet fever; (6) there is not apt to be the strawberry tongue in quinine rashes.

Method of Applying Hodgen's Splint.—Dr. George S. Brown of Birmingham, Ala., demonstrated in Dr. Hearn's clinic at the Jefferson Hospital, November 16th, his very excellent method of applying the Hodgen splint for fracture of the femur. The point of suspension is about eight feet above the floor on a movable gallows. Tent blocks on the four cords suspending the splint allow the easy adjustment of its position. Spring scales are inserted between the supporting cord and the four splint cords. When the splint is applied the gallows is placed directly over the leg. The scales show the weight of the leg. The gallows is then moved back until the scales show the amount of extension required. The advantages of the method are the ease of measuring the amount of extension, the readiness with which the angle of the leg can be varied, and the facilities afforded by the movable base of support in increasing or decreasing the amount of extension.

The Characteristics of Genuine Vaccination.—At the meeting of the County Medical Society, November 13th, Dr. Jay F. Schamberg read for Dr. William Welch and himself a timely article on the above subject. The different stages in the evolution of the vesicle were described and the subject of what constitutes a successful revaccination considered. The statement was made that a revaccination should not be expected to be like the primary one. It is no more reasonable to expect the typical course in a revaccination than it is to expect smallpox after vaccination. The pock should go through the various stages, but not with the severity of a first vaccination. The modified course of the revaccination removes all liability to the disease. One of the most frequent false vaccinia conditions is that in which about the seventh day there is, instead of a vesicle, a hard, reddened area resembling a nevus. This is not protective.

The Efficacy of Glycerinized Lymph.—At the Municipal Hospital glycerinized lymph is used to the exclusion of all other vaccine material and uniformly good results have been obtained. No one in the institution has had smallpox after a timely vaccination with the material mentioned. Its value in primary vaccinations has been tested in the case of nurses and others. Different results by various observers may be explained in one of two ways: (1) The material used by them was not equally reliable, or (2) they differ as to what constitutes a true vaccination. If the first be true, it points strongly to the Government control of all lymph used.

Details of Vaccination.—Attention was called to the fact that Jenner and others used only the serum of the vesicle. Now the lymph, vessel-walls, and epithelium are scraped and used. This may account for the numerous sore arms met with. Patients at the Municipal Hospital are vaccinated at once when an epidemic is present. Vaccination, when the patient has other disease, as diphtheria or scarlet fever, appears

to make no difference. If a child is vaccinated in infancy and again at puberty it should always remain immune. Exceptions may warrant revaccination when there is an epidemic. Tight-fitting shields are condemned. They may be worn a few hours while the material is drying, but if continued they do more harm than good.

CHICAGO.

Exemption from Smallpox.—The continued exemption of the city from smallpox is a source of gratification to the Health Department, and Commissioner of Health Reynolds is disposed to attribute it largely to the work done last winter by the contagious disease division, under the Chief Medical Inspector, Dr. Heman Spalding. During the first twenty-three months of the recent outbreak—March, 1899, to January, 1901, inclusive—a total of 480,629 persons were examined as to their vaccinal status, and of this number 135,358 were found to require vaccination, and were duly vaccinated by the medical inspectors, public vaccinators and other attachés of the Health Department. These figures show that much more than one-fourth of nearly half a million of the population of Chicago were unprotected against smallpox and were liable to contract the disease if exposed to the contagion. In February, 1901, a wholesale vaccination campaign was pushed by every available means, and during the twenty-three working days of the month 303,725 persons were examined, but only 44,904 were found to require vaccination, a proportion of less than 15 per cent. These figures show an improvement of 47.5 per cent. in the vaccinal status of the population, a reduction of 456,280 in the number of susceptibles out of the total 960,588 persons examined during the thirty months of the outbreak.

Check on Hospital Employees.—County Hospital employees and students of medicine who frequent the institution will have strict regulations to face or a set of new rules presented to the County Board by a special committee. Employees are prohibited from having any business relations involving patients or the dead with solicitors, undertakers, or claim agents. Friends of weak, discharged patients are to be notified when the patients are discharged. Alcoholic patients are to be barred. Detailed records of property possessed by the patients are to be kept by a custodian under bonds. History sheets of each case must be carefully kept. It is believed these rules will be passed by the Board.

The Hospital Idea in Maternity Cases.—Dr. Jos. B. De Lee, in a recent paper, stated that during the year 1900, 29,568 births were registered in Chicago. During the same twelve months 258 deaths of mothers were recorded. This shows that one mother in 115 cases dies. Granted that all the births are not reported, the percentage of deaths will again be reached when one adds in all the deaths at this time that are sent in under another diagnosis. Make the greatest allowance for errors common to statistics, and say there is one death in 300, or even one death in 800, is not this mortality too great if it can be avoided? And it may be. The amount of sickness, of permanent invalidism, caused by improper or insufficient care at this time cannot be shown by figures, but the books of every physician and the records of the dispensaries and the hospitals bear testimony to such woes. In this city, during the same year, 1900, 2,144 children failed to see the light of day, and 1,770 more died a short time after birth, a total of 3,914 in 29,568 births, that is, 13 per cent. of all children die in a few hours. This is not accurate, because not all the births are recorded, while the deaths all are, but the figures show an enormous infant death-rate, to check which something ought to be done. Statistics show that one-third of the blind in this State have lost vision through the ignorance and carelessness of their attendants at the time of birth. Enough has been said to show that childbirth at present is not as perfectly normal and safe as it is usually considered, but that there are many dangers. Many of these may be avoided by giving the physician-accoucheur the advantages enjoyed by the surgeon. It is an admitted fact that fewer women die in the maternities than at home. The Chicago Lying-In Hospital Dispensary Service in the Maxwell Street district and its lying-in hospital have had 1,908 consecutive obstetric cases without a death, which shows what may be done by proper precautions. The reasons that fewer women die in the lying-in hospitals than in their homes are patent at first glance. These hospitals are specially equipped to handle maternity cases. The demands of antisepsis are fulfilled as they never can be in a private home, however affluent. The physician has plenty of appurtenances wherewith to work, and he has plenty of help. The nurses of a lying-in hospital, separate day and night nurses, are under the supervision of a superintendent who has had years of experience and together they do much to protect the mother and child from sickness, to detect abnormal conditions, and to report them at once to the physician. The house physicians, too, have the patient under constant surveillance. The incubator, with its warmed, filtered, and moistened atmosphere, is at hand. If a woman has a commodious home, and can afford to fit it up like a hospital, and employ several physicians and day and night nurses, many of the objections to the home will vanish, but for the vast majority of women these conditions cannot be obtained, and therefore it is not fair to the mother, the babe, or the physician, when an obstetrical emergency arises, to condemn them to make-shifts of a private house. Furthermore, the hospital is more economical, and from a domestic standpoint there are distinct advantages. All commotion and confusion are avoided. The patient is relieved of all responsibility, is not worried by the petty annoyances of the home, her callers are limited to a safe number, and the infant is taught habits of regularity regarding feeding and sleep.

Property Purchased by Illinois Medical College.—This college has purchased a piece of property, 50 by 100 feet, at the southwest corner of Washington Boulevard and Halsted street, for $45,000. After making extensive changes in the building, it will be used as a medical college and dispensary.

Chicago Medical Society.—At a meeting held November 13th, Dr. F. C. Hotz reported a case of symblepharon of the lower lid which was relieved by skin-grafting. Dr. E. F. Syndacker described and demonstrated Kronlein's operation for exposure of the posterior orbital space without the removal of the eye. Dr. Frank Allport read a paper entitled "A Search for the Truth Concerning Tenotomies for Muscular Insufficiencies." Dr. C. P. Pinckard reported a fatal case of tetanus following an eye injury.

GENERAL.

St. Louis Medical Society of Missouri.—Dr. E. C. Renaud read a paper on "Sympatheticectomy in Optic Nerve Atrophy" before this Society, Saturday, November 16th.

Herb Doctors in England.—It is reported that some weeks ago the Apothecaries' Society, a licensed medical body, lost a case against an herb doctor, who sold medicines, so-called, which caused the death of a child, but who was protected by the court on the strength of an ancient law passed at the time of Henry VIII., giving herb doctors a special privilege.

Suicide in French Army.—The statistics published in the *France Militaire* show that cases of suicide are very frequent in the French Army, more so, perhaps, than in any other European force. Among every 1,000 deaths in the army from all causes, no less than an average of fifty (in 1896 exactly fifty and in 1897 fifty-one) are caused by self-destruction; while of every 100,000 men on the rolls of the army no less than an average of twenty-seven commit suicide every year. Among the colonial troops the number is even higher.

Cancer Study in Germany.—Kaiser Wilhelm has commissioned Professor Ehrbach, the well-known bacteriologist and physiological chemist, of Frankfort-on-the-Main, to devote himself henceforth exclusively to the study of cancer.

Case of Plague in London.—A case of bubonic plague was admitted last week into Hammersmith's Hospital. The patient is a resident of Chiswick and had been employed on a tug working between Brentford and Greenwich, on the River Lee, for three weeks before he was taken to the hospital.

Plague in Liverpool and Glasgow.—The presence of plague is officially announced in these cities. At least 7 cases have occurred in Liverpool with 2 deaths.

To Investigate Plague.—Assistant Surgeon John F. Anderson of the United States Marine-Hospital Service has been detailed by President Roosevelt to go to Liverpool and investigate the recent outbreak there of the bubonic plague. He will report to Washington on the prevalence of the plague and the possibility of its continuance and spread and the danger of its transmission to this country. He will also make such recommendations as will protect the ports of this country from the disease.

Virchow Fund Increasing.—In order to celebrate in some fitting way the eightieth birthday of Rudolph Virchow (October 13, 1901), it was decided last year by a committee of professors and physicians in Berlin, to ask for further subscriptions to the Rudolph Virchow fund. This fund was started ten years ago to celebrate the seventieth birthday of the great scientist by providing him with the means of facilitating scientific research by establishing scholarships and by encouraging special medical and biological studies. Subscriptions to this addition to the fund were asked for from physicians in all parts of the world and committees were formed in every country, to take charge of the local collections. About 200,000 marks ($48,000) had been collected from all over the world up to July 1, 1901, but only a very small proportion came from this country. Since the first of last January 50,000 marks have been added to the original fund. Of this 3,000 marks, approximately $720, came from the United States. The scholarships when they are founded are to be awarded to students of any nationality who stand first in a competitive examination which will be held once in a given period in Berlin. The number of scholarships and the details in regard to the examinations have not yet been decided upon. Subscriptions from Americans should be sent to Dr. A. Jacobi, 110 West Thirty-fourth street, New York. The American committee in charge of the subscriptions are C. A. L. Reed, President of the American Medical Association; H. P. Bowditch, President of the Congress of American Physicians and Surgeons; W. K. Welch of Johns Hopkins University; R. F. Weir, President of the New York Academy of Medicine, and A. Jacobi, Secretary.

A Local Typhoid Epidemic.—The following interesting account of a local typhoid epidemic in Germany is reported in the Marine-Hospital Service Bulletin. There are probably few parts of Germany which are so frequently smitten with infectious diseases as that known as the Ruhrkohlenrevier (Ruhr Coal District), which extends from Duisburg to Hamm, and takes its name from the River Ruhr which flows through the country in the direction from east to west. Generally the world hears nothing of these little epidemics, as most of them are limited in extent and not very dangerous. But it was quite different with the great typhoid epidemic which suddenly broke out in September in the district of Gelsenkirchen with a violence that has probably never been observed before. The notification cards which the physicians have to fill out arrived at the office of the district police authorities in such large numbers that it was quite evi-

dent that the various cases had a common origin. As early as the beginning of September, single cases of typhoid fever were reported, but no special importance was attached to this fact, as every year a number of such cases have to be recorded. Toward the middle of September the cases increased to such an extent that the authorities became alarmed, and immediately took in hand the combating of the disease with the greatest energy. As in most cases water has been found to be the bearer of the typhoid bacilli, the inhabitants of the district were warned of the danger of drinking water unless it had been previously boiled. The whole neighborhood of Gelsenkirchen is supplied by the waterworks for the northern coal center, and as the spread of the disease corresponded exactly with the district supplied by this water system, it was natural to suspect that in some unexplained manner typhoid bacilli had gotten into the water system and had there increased to an exceedingly dangerous extent. This supposition was strengthened by the observation of the fact that the main water pipe leads from Steele, a place on the River Ruhr about an hour's walk from Gelsenkirchen, where the water supply is taken in, through the commune of Rotthausen, which belongs to the Rhine Province, to Gelsenkirchen. Cases of typhoid fever occurred in all the houses in Rottshausen which derived their water supply from the main pipe, while the occupants of those houses located at a distance from the main pipe and who derivd their water supply from wells remained free from the disease. The announcement of Dr. Koch, who was hurried to the spot in order to place his services at the disposal of the authorities in combating the disease, that he intended to avail himself of the permission of the president of the district to lay open the whole system of pipes by excavations had the effect of forcing the managers of the waterworks to make the disclosure that from the River Ruhr a direct pipe led to a water reservoir, which was mostly used from Wednesdays to Sundays, and that therefore unfiltered water had been pumped into the pipes out of a river in which the drain pipes of the whole district were emptied, and this pipe with its loathsome contents was still in use up to September 25th, a date at which the disease had been raging in a terrible manner for fourteen days. Further investigations have been opened, and it is to be hoped that the avenging arm of justice will reach those who are to blame for the misfortune that has befallen the district.

Obituary.—Dr. Albert L. Gihon, former Medical Director of the United States Navy, died of paralysis last Sunday morning. Dr. Gihon was sixty-nine years old, having been born in Philadelphia in 1833. He attended college in Princeton and obtained his medical degree from the Philadelphia College of Medicine and Surgery. From 1853 to 1854 he was professor of chemistry and toxicology in this institution and in 1855 entered the navy as assistant surgeon, and was assigned to the sloop of war "Portsmouth," taking part in the battle which resulted in the capture of the Barrier forts in November of the following year at Canton, China. He served in various ships until 1860, when he was assigned to the Brooklyn Naval Hospital for a year. During the last three years of the Civil War he was on the "St. Louis," which did special duty as a privateer hunter. At the close of the war he became the senior medical officer at the Portsmouth Yard. He was awarded the decoration of Knight of the Military Order of Christ by the King of Portugal for his services on the Portuguese men-of-war "Principe Dom Carlos" and "Sa da Bandeira" and in the Portuguese colony at Dilly, on the Island of Timor. In 1870 he became surgeon of the fleet on the European Station. Dr. Gihon designed the model hospital ship which was exhibited at the Centennial Exposition of 1876, and the ambulance cot approved and used by the navy was designed by him. He became Medical Director in 1879, and later served at Washington, Mare Island, Brooklyn, and New York. In 1893 he was transferred to the post at Washington in charge of the medical headquarters. He was then senior medical officer of the navy, and was placed on the retired list in 1895, having reached the age limit of sixty-two years. Dr. Gihon wrote a great many technical books on medical matters, some of them having been used as textbooks. He also did editorial work for several medical magazines, among which may be mentioned the *Reference Handbook of the Medical Sciences, Annual of Universal Medical Science* and *Twentieth Century Practice.*

Dr. Isaac R. Small died November 13th, at his home, 175 Halsey Street, Brooklyn, in his seventy-seventh year. He was a graduate of the College of Physicians and Surgeons of New York and practised for nearly forty years in Greenpoint. He served one term as coroner of the Eastern District of Brooklyn.

Dr. Samuel Ashhurst of Philadelphia, died in London, England, November 13th. Dr. Ashhurst was born in Philadelphia, receiving his early education at Amherst College and his professional training at the University of Pennsylvania, from which he graduated forty years ago.

Dr. David C. Reynolds died November 12th at the age of seventy-one. He came to Philadelphia from Lock Haven in 1876. Dr. Reynolds was the founder of the Commonwealth Provident Association in 1888 and was its medical director.

Dr. William F. Norris died in Philadelphia November 18th. Dr. Norris was professor of ophthalmology at the University of Pennsylvania. Death was due to pneumonia. Dr. Norris came from one of the oldest Philadelphia families, being born here in 1839. He graduated in medicine in 1861 and served as assistant surgeon during the Civil War. Dr. Norris held many important positions in local and national medical societies and was the author of numerous papers and treatises on ophthalmological sub-

jects. He also wrote a widely used text-book on ophthalmology.

Dr. Jarvis S. Wight, a well-known Brooklyn physician, died Sunday at his home, 30 Schermerhorn Street, in his sixty-seventh year. He was a descendant of Thomas Wight, an emigrant from the Isle of Wight, who came to this country in 1635. Directly after his graduation from the Long Island College Hospital in 1864, he went to the front as an assistant surgeon in a Volunteer regiment, serving until the close of the Civil War. All through his practice, he retained a close connection with the Long Island College Hospital, holding the position of professor of operative and clinical surgery until the close of his life. He was also consulting surgeon at St. Mary's Hospital and at the Eastern District Hospital. He belonged to all the leading medical societies. He invented numerous surgical instruments and was the author of several works including the following: "The Weight and Size of the Body and Its Organs," "Myodynamics, or the Dynamics of the Muscles," "A Memorial of Frank Hastings Hamilton, M.D.," "A Biographical Memorial of O. W. Wight, M.D.," and "Suggestions to the Medical Witness." His son, Dr. Jarvis S. Wight, Jr., survives him.

CORRESPONDENCE.

OUR LONDON LETTER.

[From Our Special Correspondent.]

LONDON, November 9, 1901.

THE REPORTS AS TO THE KING'S HEALTH—BAD EFFECT ON TRADE—HOW THE RUMORS MAY HAVE ARISEN—BIRTHDAY HONORS.

THE rumors as to the King's health to which reference was made in my last letter have caused a good deal of excitement among people of all ranks, and, what is worse, are having a marked influence on the many branches of trade that depend on State ceremonials, and the displays and festivities which are the breath of life of a court. During all the long years of her widowhood Queen Victoria lived in retirement to the serious detriment of those who make it their business to purvey luxuries to the fashionable world. So depressing, indeed, was the effect of her long mourning on trade in London, that at one time it threatened seriously to impair her popularity. Court dressmakers, man milliners, carriage builders, jewellers *et hoc genus omne,* looked forward on the King's accession to a livelier state of things after the official year of mourning was over. But the fact that these cancer rumors, which have till lately only been current here in whispers, have now been bawled aloud in the press, has made both courtiers and their tradesmen very uneasy. Orders for coronation robes are being countermanded or held in suspense by peers and high priests and others who have the privilege of arraying themselves in gorgeous apparel on such occasions; and the result is that a large number of workers of one kind or another who had been engaged by the Court purveyors are being thrown out of employment. I can state with the most positive certainty that there is no shadow of foundation for the rumors. The Court physicians could not go holiday-making in distant parts, as they have been doing quite lately, were there but a cloud no bigger than a man's hand in the farthest corner of the sky; nor would they be going about in society with every outward and visible sign of minds perfectly free from care had they so portentous a secret locked in their breasts. One must have seen the keeper of a sovereign's health when the august patient is really ill to realize the nervous tension caused by such a responsibility. It has not been considered expedient to give any official denial to the rumors; in the first place, because there are many people who never believe a thing until it has been officially denied; and, secondly, because if this particular rumor were denied now, another to the effect that the King had tuberculosis or some other serious ailment would probably have to be denied the next week.

The fact is that King Edward has all his life spoken as if he had a plum in his mouth. Like all his family he speaks with a thick guttural voice and a German accent, which people who wish to be thought fashionable try to imitate, to the grievous discomfort of Englishmen, who like to hear their mother-tongue spoken as it should be. The royal voice has with the advance of age acquired a huskiness akin to that noted by the Lord Chief Justice in Falstaff, who attributed it to "hollooing and singing of anthems." I do not know whether our gracious sovereign is much given to the singing of anthems, but he is of full habit and bears about him the signs of a long perseverance in good living. He smokes a good deal, and suffers occasionally from the pharyngitis that is one of the penalties of over-indulgence in the "herb nicotian." Twelve or thirteen years ago he consulted Morell Mackenzie about his throat which was then troubling him. The royal patient thought it necessary to assure the physician that he did not drink like one of his brothers at whose palace gate Pale Death has since knocked. The Prince, as he then was, asked the physician if there was any sign of cancer. Doubtless the recent death of the Emperor Frederick had made him anxious, as it did thousands of meaner mortals. But Mackenzie was able to reassure him. Possibly the death of his brother, the Duke of Saxe-Coburg, better known perhaps as Duke of Edinburgh, and of his sister, the Empress Frederick, from cancer, may have suggested to His Majesty the possibility of a similar fate for himself. But as far as medical science can pronounce at present there is, as I have said, not the slightest appearance of a growth in the larynx, nor is there anything in the King's condition, local or general, calculated to give rise to the suspicion of cancer.

This by the way is the anniversary of the King's entry on what a more famous monarch called "this great stage of fools," and, in accordance with usage, a list of "Birthday Honors" is published in the newspapers. The medical profession is, as has of late years become the rule, conspicuous by its absence. One poor knighthood falls to its share, and that may be taken more as a recognition of official position than as a reward of scientific eminence. The man whom the King delights to honor is Mr. Anderson Critchett, His Majesty's oculist *en titre*. Mr. Critchett is a man of charming manners and great social accomplishments, but his professional position is largely due to the reflected glory which comes to him as the son of his father. It was thought to be certain that Mr. Malcolm Morris, the Secretary General of the Tuberculosis Congress, would have received an honor of some kind. He worked very hard to make the Congress a success, and it is generally admitted that it was one of the most successful meetings of the kind that have ever been held. The King himself showed a great interest in the Congress, and was very gracious to a deputation of the officers of the meeting who waited upon him to report the issue of the proceedings. It was expected that His Majesty would have shown Mr. Morris some mark of his favor then. Now it is pretty evident that he has been deliberately passed over, and the explanation is probably not far to seek.

The principalities and powers of the profession have been handled with considerable freedom in the *Practitioner,* of which Mr. Morris is editor, and those magnates have a very exalted sense of their dignity. There is nothing they less easily forgive than the crime of *lèse-majesté* committed against their own persons. Moreover, Mr. Morris is recognized as the originator of the movement against tuberuclosis which is steadily gaining strength in this country. This is an offence to certain high and mighty "leaders of the profession" who have the ear of some of those who have the ear of others who have the ear of the King. If it were not that these honors have among our title-worshipping public a distinct commercial value, it would be difficult to conceive that any self-respecting man would care to accept one. They are mainly only to be got by intriguing and plaguing the "lusty beggar." A title may, however, have value of another kind. A well-known Member of Parliament tells me that if you dine out much it is worth while to be a baronet because you have less chance of getting cold soup.

ACUTE GASTRIC DILATATION—PRIMARY CHRONIC GLAUCOMA AND IRIDECTOMY—HEMATURIA IN CHILDREN.

H. CAMPBELL-THOMPSON, at the Royal Medical and Chirurgical Society, October 22, 1901, read a paper on acute dilatation of the stomach and outlined the symptoms as follows: The increase in size gives rise to abdominal distention, which is not uniform, but fills chiefly the left and lower parts of the abdomen. Meanwhile as a rule the right hypochondriac region is comparatively or entirely flat. Such a swelling is strongly suggestive of a gastric inflation, but at times irregularities occur in so far that retraction and uniform enlargement have both been noted and reported. One factor is probably the amount of fluid in the stomach, for the swelling usually changes in form and dimensions after vomiting and after gastric siphonage. Peristalsis has not yet been observed with certainty, which seems to oppose the theory that spasmodic pyloric stenosis is the cause of the dilatation. Vomiting, if present, is usually without much straining and commonly brings up large quantities of brownish or greenish fluid. The urine is always partially and often entirely suppressed during the last twenty-four hours of life. In some cases which presented symptoms of retention a catheter proved the bladder to be entirely empty or containing only a few drops. The general symptoms are those of collapse, small thready pulse, rapid feeble respirations, low or subnormal temperature, excessive thirst, probably due to the vomiting of fluids. The postmortem appearances of the stomach are very characteristic; it is shaped like a cylinder, bent upon itself to form a V, with a sharp angle between the limbs which the lesser curvature forms. The walls do not lose their elasticity, although the size of the organ is so much increased, nor are they much thinned out. This is shown by the facts of the vomiting during life and of the rapid return to practically normal size after death if the fluid contents are quickly evacuated. It seems as if there were no definite abnormalities of the walls that can be discovered. The intestines as a rule are flattened, but may show some distention, more especially of the cecum and of the ascending colon. It seems as if the cause of the disease were some profound nervous disturbance which by provoking a hypersecretion rapidly filled up the cavity to enormous proportions. It is very likely that a hyperproduction of gas, as after drinking an excessive quantity of effervescing fluids, may also tend to produce the condition.

D. LITTLE, at the Ophthalmological Society, October 17th, related his experiences with primary chronic glaucoma and its relation to iridectomy. There is a growing unanimity of the profession among ophthalmologists pointing to a primary iridectomy or a sclerotomy backward from the corneoslerotic juncture. He then reviewed forty cases in which he had done this operation with or without a removal of the iris. On the whole he considered an iridectomy the more reliable and satisfactory procedure and at a later date often adds the linear sclerotomy of a persistence or a recurrence of the symptoms seems to demand it. It is always necessary to keep the patients under observation for a long

time after the primary operation has been done, both because the effects of the treatment must be followed and because an acute recurrence of the trouble in the same or in the opposite eye is possible.

C. Williams, at the Harveian Society of London, October 17th, read a paper on hematuria in childhood in which the causes were enumerated as parasites, chemicals, tuberculosis, and traumatism especially by calculi.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Section on Orthopedic Surgery.

Stated Meeting, Held October 18, 1901.

George R. Elliott, M.D., Chairman.

Infantile Paralysis Simulating Congenital Talipes Calcaneus.—Dr. A. B. Judson presented the case of a baby five months old with what at first view appeared to be left congenital talipes calcaneus. Passive motion was abnormally free; active motion was deficient. The position was that of talipes calcaneus. The history was given of a three days' sickness occurring when the child was two months old, in which there were fever, trembling and general cutaneous hyperestheria, but no vomiting, diarrhea or convulsions. The diagnosis of infantile paralysis was made and will probably be confirmed by partial spontaneous recovery during the next year. The cutaneous circulation was apparently normal and the general health of the infant was excellent. The left thigh and leg were ½ less in circumference than the right. The arms were normal. Congenital calcaneus was rare. Such a case with the resistant tissues and lasting deformity of congenital varus would be well worth careful study and description.

Dr. W. R. Townsend agreed with the diagnosis of infantile paralysis. He believed well-marked congenital talipes calcaneus to be very rare, although he had seen such cases.

Dr. Henry Ling Taylor said in reference to the statement about the rarity of congenital talipes calcaneus that, while he agreed that the severe forms were rare, the milder varieties were fairly common; they, however, usually corrected themselves without special treatment.

Crepitus in Cervical Pott's Disease.—Dr. Judson presented a case of crepitus heard in cervical Pott's disease in a woman forty years old, accustomed to house-work. Symptoms had been present about a year. Movements of the head had caused pain in the forehead and face called by the patient "neuralgia." She often supported the head with her hands and at night needed a number of pillows carefully arranged to hold the head in a comfortable position. When she stopped work for a time she felt better, but on returning to work the trouble was increased. The deformity was marked, being partly due to a forward displacement of the axis of the head, a condition invariably present in cervical Pott's. The width of the neck posteriorly was increased. There was no abnormality of the trunk or any other part of the skeleton. She said that at one time the head was much flexed and inclined to the left. Six months ago she noticed that motion of the head in rotation was accompanied by a cracking sound. On examination the crepitus was readily heard, simulating bony crepitus, but evidently due to tendinous or muscular slipping.

Dr. Townsend said that he could not agree with the diagnosis of cervical caries; he was inclined to consider the case one of osteo-arthritis which diseased condition had been well described by Goldthwait in the *Transactions of the American Orthopedic Association*, Vol. XII.

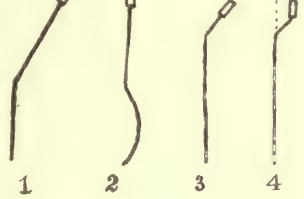
Dr. Elliott agreed with Dr. Townsend that the symptoms and objective signs were not typical of cervical caries. He would expect to find more real disability, more rigidity due to reflex spasm in spite of the fact that frequently the symptoms and signs of caries in the adult were frequently masked. Cervical caries appearing at the age of forty was not common, and at that age almost invariably progressive, which did not appear true in the present case. The crepitus, too, which was elicited so markedly upon free movement of the neck, rather pointed to another disease.

The word *caries sicca* he believed to be largely a pathological misnomer.

Dr. Taylor agreed with the two foregoing speakers. He thought the patient should have shown more severe symptoms and more tendency to progress were it a case of caries.

The indications for treatment, however, of osteo-arthritis and tuberculosis of the spine were the same, as far as protection and support to the diseased vertebræ were concerned.

Dr. Judson expressed himself as unable to amend his diagnosis. He considered the case as a typical one of cervical Pott's disease and recalled the symptoms in detail. He took the opportunity to call attention to an important sign of disease in this region. Figures 1 and 2 showed how the lordosis accompanying deformity in the dorsal region was unconsciously assumed by the patient for the preservation of his equili-



brium. This has been well shown in the photograph exhibited by Dr. H. Gibney at the meeting held October 19, 1900. In cervical disease, Figures 3 and 4, the equilibrium was not seriously disturbed, but the necessity of a horizontal visual axis led to extension of the head at the occipito-atloid articulation with the characteristic forward displacement of the axis of the head

seen in Figure 4 and in the patient who had been presented.

Osteotomies for Correction of Bow-Legs and Knock-Knees.—Dr. Homer Gibney presented six cases and described method employed. Three of the cases shown were very marked anterior curves of tibiæ entirely corrected. Tracings, photographs and notes from the records of the Hospital for Ruptured and Crippled were presented.

Dr. L. A. Weigel of Rochester said that he was somewhat in doubt as to what constituted a true bow-leg and the proper course to pursue in a certain class of cases. An outline tracing of the leg might show an apparent bowing while a skiagraph would demonstrate that the shafts of the leg bones were straight. He exhibited skiagraphs of two cases to illustrate. In one of the cases the deformity was corrected by osteoclasis, but the skiagraph showed that the legs were straightened by making the bones slightly crooked.

Dr. Townsend agreed with Dr. Weigel about straightening legs often by making them "crooked." He had found frequently that in cases where the deformity was ideally corrected the bones were actually very crooked and his experience with radiographs had been similar to that of Dr. Weigel.

Dr. Taylor called attention to the importance of correcting inward rotation of the tibia in cases of bow-legs. There often existed an inward twist of 20 degrees or more and this could only be obviated by everting the lower fragments at time of operation. In the cases presented by Dr. Gibney he noticed that two of the children showed a marked inward twisting of the feet. Too little attention had been given to this point by operators. Neglect to correct this rotation meant an incomplete correction of the deformity and liability of a recurrence of the bow-leg. He advised breaking the fibula as well as the tibia, well loosening the fragments, twisting the foot out as much as possible—the resulting eversion would not be too great.

Dr. R. H. Sayre remarked that in one of the cases presented in photograph by Dr. Weigel, the thighs as well as the legs were bowed, and the bowing was accounted for probably by twisting of the neck of the femur as well as the lower part of the femur near the condyles. In many cases the distortion was found close to the epiphyses, while the shafts of both tibia and fibula were straight. Operation should be performed at the point where deformity existed.

Coxa Vara.—Dr. Taylor presented a boy first seen by him in May, 1900, then six years old. He gave the history of having walked at the age of eleven months and of having been lame in the left leg ever since. There was one-half inch shortening of the left leg, the trochanter was elevated one-half inch, and the head of the femur could not be felt. The symptoms pointed to coxa vara, but he had not known of any other cases of this disease beginning at such an early age. A skiagraph showed that the head of the bone was in the acetabulum and that the neck was bent downward. There was no evidence of rachitis. The leg at present was smaller than the right; abduction and outward rotation were limited, other movements were free; shortening and elevation of the trochanters were the same. There had never been any pain.

Dr. Sayre said he should judge from the skiagraph that there had been a fracture of the neck of the femur; the inability to secure history of traumatism did not necessarily have any weight. The child had not been seen till six years of age and gave the history of walking at eleven months and limping. He judged that this might be a case of fracture or of epiphyseal separation.

Dr. Weigel suggested that, if there had been epiphyseal separation the action of the muscles would have tended to draw the trochanter and shaft upward, the head being retained in the acetabulum.

Dr. Sayre said that would depend on the extent of the fracture —in other words, whether it were complete or not.

Dr. Taylor said that there was a history of several falls, none of them severe nor followed by symptoms of injury. It was evident that coxa vara was present, whether the result of traumatism or malformation.

Dr. Weigel read a paper on "Skiagraphy in Othopedics," illustrating his discourse with many negatives adjusted in the X-ray stereoscope which he used. A brief reference was made to the technic of stereoscopic skiagraphy and the advantages over the ordinary method of producing X-ray negatives were fully explained. The technic was not difficult. He considered one of the principal difficulties in skiagraphy the proper interpretation of the negative in the stereoscope. The idea of depth was given which was not apparent when viewing the negative alone. By reversing the negatives in the apparatus the pictures could be viewed from the opposite surface.

Dr. Weigel also presented the subject of "fractures and dislocations in tuberculous joint disease," with illustrative skiagraphs. One of these was of a boy who was said to have double congenital dislocation of the shoulders, which proved on careful examination to have been tuberculous destruction of the joints, with partial dislocation. On one side an abscess cavity of large size communicated directly with the joint. In another case, involving one elbow-joint and forearm, the necrotic process gradually attenuated the shafts of the radius and ulna. Eventually a complete separation of the latter bone occurred about one inch below the joint and allowed the bones of the forearm to slide upward and backward.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, Held November 11, 1901.

The Vice-President, William McCollom, M.D., in the Chair.

The General Aspects of Corneal Astigmatism.—Dr. H. D. Saril said that by reason of

its predominating influence on the causation of asthenopia, kindred neuralgias, and various sequelæ, astigmatism merits early recognition and optical correction. This defect is largely congenital, heredity playing an important rôle. It is aggravated largely by persistent ocular effort, but may be modified by reverse conditions. The amount of innocuous accommodation possible for the eye to perform is a matter of personal equation. The greater the optical error, as a rule, the less the physical inconvenience, but in direct ratio to this is to be found the diminution of visual activity. Astigmatism exists to a greater or less degree in all human eyes; but the term physiological, as applied to this condition, is an arbitrary one. The annoyance caused by an uncorrected or, reversely, by a forcibly corrected astigmatism depends upon the occupation of the individual, as well as on the power of personal resistance. The greater burden falls on those engaged in scholastic or clerical work, and is almost *nil* for the laborer. It is evident, therefore, that one may be affected with headache, neuralgia, blepharitis ciliaris, singly or collectively, whereas another remains immune. The pupil is an important factor in regulating the configuration of the astigmatic pencil, and upon its size being favorable to the prevention of diffusion circles depends much of the correction of ametropia in general. The feature of greatest interest lies not so much in the quantitative or qualitative change in the refraction of a given meridian, as in the axial transition. In these latter cases a principal meridian to within any degree of a quadrant presents the same or a similar degree of astigmatism as its congener. The resulting condition is that, from being with the rule in certain cases, it becomes against the rule, and in others oblique. All varieties of optical vagaries are possible under these circumstances. When the astigmatism reaches 1.5 D. in childhood there is but rarely any marked deviation during many following years. As a rule, stability of refraction belongs to early middle life. As presbyopia develops, and particularly after it has been well established, the tendency of astigmatism with the rule (direct) to become against the rule (perverse) is very marked.

The subjective symptoms of astigmatism are those of asthenopia in general.

Encysted Empyema.—Dr. J. Blake White said that acute empyema is much more common, especially in children, than generally supposed; is difficult to detect when there is only a moderate exudation and is sometimes overlooked until constitutional conditions or lung perforation results. This latter accident more frequently follows the encysted variety of empyema, a circumstance explained by the more confined character of the cavity and the more yielding nature of the lung tissue constituting one wall of the abscess. Its existence is not so readily recognized by dulness on percussion or absence of respiratory murmur as the books state, and an examination based on these evidences will often fail to discover it. Individuals of strumous diathesis are extremely liable to empyema after a more or less severe attack of pleurisy or pneumonia. It was at one time thought that evacuation of the pus through a bronchus promised recovery, or was the best result that could be looked for. We now know that this natural means of emptying a pus cavity is the worst, as it infects a large area of lung tissue, produces pus pockets in many places, and permits septic absorption. Dr. White gave a detailed report of three cases. The fourth, on account of its similarity to one of the others, was not narrated. Two of them seemed to illustrate how readily an encysted abscess may occasion perforation of the lung. In one case evidences of permanent pulmonary disease, with tubercle bacilli in the sputum, ultimately disappeared when external drainage was established. In this case the drainage-tube was retained for about nine months. Resection of the rib was done in two of the cases, but not in the others. In regard to this procedure he said that, while some believe it should be performed in every case of empyema operated upon, his experience led him to regard it as unnecessary as a routine practice. In the very young quite as satisfactory results are generally obtained without resection, as with it. The main point is perfect drainage, and if this can be secured without resection it should be done. Such a result may be accomplished by using a rubber tube of sufficient caliber and resistance to maintain drainage as long as required and to overcome the pressure upon it caused by granulation tissue. Whether to resect or not must be determined by the special features of each individual case. Irrigations are to be deprecated except in rare instances. Their routine use is injudicious and sometimes dangerous. This objection does not apply to cases of gangrenous abscesses or to those of long continuance which are discharging pus. At the close of the paper Dr. White exhibited a modification of Beck's rib-shears devised by himself, which he said he had found very efficient.

The Early Recognition of Serous and Suppurative Pleurisy.—This paper was read by Dr. James K. Crook, and will appear in a later number of the Medical News.

Resection of the Rib Should Be Performed in All Cases.—Dr. Carl Beck said he was well aware of the great difficulty in making a diagnosis between abscess of the lung and encysted empyema. Thus, sometimes there is a large fibrinous clot surrounded by fluid. Fortunately, we have now a very efficient aid to diagnosis in the Röntgen rays. Dr. Beck then presented a very fine radiograph of the chest, and said he did not believe that abscess of the lung could be more clearly demonstrated than by such a picture. There could be no question as to the advisability of incision, but it was not sufficient; and for more than fifteen years he had insisted on resection of the rib in all cases of empyema. If there were always simple empyema, incision

alone might perhaps answer; but in over forty per cent. of the cases there are fibrinous clots present. By means of resection we can make a satisfactory exploration and a thorough evacuation. Dr. Beck stated that in his latest rib-shears the character and length of the curve was very much the same as in the instrument shown by Dr. White.

Perforation into the Pleura.—Dr. Egbert Le Fevre said that during the last few years he had come to entertain doubt as to the frequency with which empyema perforates the lung. In two cases some time ago in which death occurred rather suddenly he found at the autopsy that the perforation had taken place from the lung into the pleura, and not from the latter into the lung. Since then he had seen numerous similar instances in the morgue. These cases showed that from a bronchiectatic cavity perforation into the pleura may take place; so that he was still in doubt as to the frequency with which a localized pleurisy results in perforation of the lung. As to simple empyema, it was doubtful whether it was possible for perforation to occur from this condition; but if the empyema were localized, with adhesions, perforation might sometimes take place.

Former Mortality of Empyema.—Dr. T. E. Satterthwaite said that when he was house-surgeon at the New York Hospital seven cases of perforated wound of the chest were admitted in which pleurisy occurred. In three the effusion was serous and the patients recovered, but in the other four it was suppurative and the patients all died. At that time no attempt was made by surgeons to operate in empyema, and he was so impressed with the dismal results met with that in connection with Dr. A. McLane Hamilton he devised an apparatus for pumping out the chest. It consisted of a trocar and cannula attached to a Davison syringe, and was a modification of Morrill Wyman's evacuator.

Objections to Resection.—Resection is objectionable (1) because it deforms the chest by injuring the bony walls of the latter, and (2) on account of its liability to give rise to infection. But, in spite of such objections, it is sometimes required, and it is only the radical measures that have made the present mortality in empyema so small.

Measures for Avoiding Resection.—Dr. R. T. Morris said he would like to ask Dr. White whether he had ever used Murphy's method of injecting nitrogen for the purpose of absorbing the point of adhesion. By this means extensive rib resection can be avoided. Phelps' valve also serves a like purpose. It consists of a tracheotomy tube with a rubber dam. It should not be used when there are new adhesions, however, as it may then cause tearing of the lung. As to the extensive fibrinous lymph-masses referred to by Dr. Beck, these can be liquefied in about three hours by means of pepsin introduced through a small incision. But, while extreme rib resection may be avoided by such measures as these, the operation is sometimes absolutely called for.

Dr. White said that he had often observed evidences of apprehension on the part of the patient when touching the affected side. As to irrigation he said that a pretty wide experience and observation had convinced him that it ought not to be practised unless there was some special and positive reason for it. In one case seen in consultation in which he had advised against it, the attending physician saw fit to use irrigation and it resulted in a metastatic abscess of the right shoulder.

BOOK REVIEWS.

PROGRESSIVE MEDICINE. Edited by HOBART AMORY HARE, M.D., assisted by H. R. M. LANDIS, M.D. Vol. III. September, 1901. Disease of the Thorax and Its Viscera, Including the Heart, Lungs and Blood-Vessels—Dermatology and Syphilis—Diseases of the Nervous System—Obstetrics. Lea Brothers & Co., New York and Philadelphia.

THE feature which makes this quarterly digest prominent, when contrasted with the various year-books and others devoted to the business of providing the practitioner with a résumé of modern progress, is the narrative and critical form in which it is written. It must be confessed that the average American year-book or annual is a vague miscellany of scissor-clippings of abstracts, arranged in departments. A certain selective action may be exercised, but such collections of bric-à-brac have proved so uniformly unprofitable because of their non-critical character that this very feature, already alluded to, as found in Progressive Medicine, should be jealously guarded by the editor, or else it, too, will go the way of all works of this class.

The department must be handled by young men, already beginning to be known in their respective specialties, and the moment that the hand of the hack abstractor shows itself, the influence of the work will suffer. Dr. Hare has been both wise and fortunate in the choice of his collaborators.

CIRCUMSTANCE. By S. WEIR MITCHELL, M.D., LL.D. The Century Co., New York.

IN this story of Philadelphia people, the real well-to-do, well-tried old-family men and women live and move in a delightful society of friendly understanding and sympathy, until an adventuress of a very charming but harrowing type works her way into the home of the aged and irascible invalid uncle, fast approaching his dotage, and becomes his secretary. We trembled lest she might have come from New York, so great was the emphasis of the different members of the old gentleman's family that no one knew where she came from; but her author considerately hails her from the Far West, and discloses a very shady past; which, however, he conceals from these "sedate and reputable people,

with their unquestioning beliefs in themselves and their ancestors, of whom they said nothing and thought much."

Verily it is good for the manners and the morals of society at large to dwell in the Quaker atmosphere of dignity and uprightness and sweet friendship that pervades the homes of Dr. Mitchell's characters. They are all intensely human in spite of their misbehavior, and very compassionate with one another's failings in defiance of cast-iron consciences.

There are three types of physicians that live in the pages of this book; the hard-worked, crude, country fellow, who comes friendless to the city and by a chance "circumstance" meets Dr. Archer, the keen, successful, able man who is never too busy to give thought to his friends, and who manages the crochety Uncle John with tact and skill, until another "circumstance" calls in the complacent, indecisive, garrulous Dr. Soper, who fusses on to the end of the story.

There is enough love and villainy to make an entertaining story, but the plot turning on the hinge of "circumstance" is not the only interest. The chief charm for the professional man lies in the characters of the lawyer, the priest, the civil engineer, the financier and the physician, all young men in the prime of life who have made the best of "circumstances."

A HANDBOOK OF PATHOLOGICAL ANATOMY AND HISTOLOGY. With an Introductory Section on Postmortem Examinations and the Methods of Preserving and Examining Diseased Tissues. By FRANCIS DELAFIELD, M.D., LL.D., Professor of the Practice of Medicine, College of Physicians and Surgeons, New York, and T. MITCHELL PRUDDEN, M.D., LL.D., Professor of Pathology and Director of the Department of Pathology, College of Physicians and Surgeons, Columbia University, New York. Sixth Edition. William Wood and Company, New York.

IT IS usual with the conventional reviewer in taking up a new edition to dismiss it with an easy reference to "our former words of commendation," but in the present instance such a method is not at all justified. This edition is in reality a new book, Dr. Delafield having retired as a co-editor, Dr. Prudden has seen fit to recast the entire work, thus bringing it on a level with modern-day pathology. It has therefore lost all of its former patchwork character, excellent as that was, and has been wrought into a strong, modern fabric, with enough of the old to make it one of the most reliable books on the subject with which we are acquainted.

The student of the present volume is to be congratulated that many of the fine-spun nomenclatural differentiations have been modified or entirely wiped out; various lesions are recognized to have normal variation in morphology and types are not unnecessarily multiplied.

A word of commendation is due to the excellent chapter on malaria by Dr. F. C. Wood, and the very fine illustration of the nerve-cell by Dr. F. Bailey. The publishers have dressed the book in a commendable manner, the many half-tone illustrations having been handled with skill.

PHOTOGRAPHIC ATLAS OF THE DISEASES OF THE SKIN. By GEORGE HENRY FOX, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, N. Y., etc. Parts I. and II. Quarto. J. B. Lippincott and Company, Philadelphia and London.

ACNE VULGARIS FACIEI, eczema erythematosum, syphiloderma erythematosum, zoster pectoralis and dermatitis venenata should offer absolutely no difficulty in diagnosis to the practitioner who has the opportunity to consult the first part of this magnificent Atlas. For those of us who cast longing eyes on Fox's larger Atlas, conjuring with the coins in the purse, it is a distinct joy that we now find a reproduction of the splendid plates published at a moderate price.

The second part contains text and plates on acne vulgaris dorsi, phtheiriasis corporis, psoriasis guttata, pityriasis maculata, variola vesiculosa and pustulata. We believe that every physician is able to purchase such a work and, moreover, almost hold it a duty that he should have such a reliable means of diagnosis at hand, especially as the publishers have done their part in bringing out such a work at so moderate a figure.

JAHRESBERICHT UBER DIE FORTSCHRITTE IN DER LEHRE VON DEN PATHOGENEN MIKROORGANISMEN UMFASSEND BACTERIEN, PILZE UND PROTOZOEN. Unter Mitwirkung von Fachgenossen bearbeitet und herausgegeben von Dr. med. P. VON BAUMGARTEN und Dr. med. F. TANGL. Funfzehnter Jahrgang. 1900. Erste Abtheilung. S. Hirzel, Leipzig.

FOR the past fifteen years Baumgarten's Jahresbericht has stood for the best in its sphere and the present collection of literature of the year 1899 is no exception to the rule. There is little to be said concerning this work that is not already appreciated. It is an indispensable part of every bacteriologist's equipment and a helpful résumé for the general scientist, medical or biological.

One feature of the work emphasizes a fact that we have had the pleasure of pointing out before, and that is that through the labors of an American, Dr. G. F. Nuttall, our literature is more than well represented in this foreign work. A comparison of this volume with other year-books of German work in other fields makes us long to have more of such able representatives in the different branches of medical science.

CLINIQUES MÉDICALES ICONOGRAPHIQUES. Par MM. P. HAUSHALTER, G. ETIENNE, L. SPILLMANN, Agrégés à la Faculté de Médicine de Nancy, CH. THIRY, Ancien Interne des Hôpitaux de Nancy. Fascicule et Planches. 1-a 7. G. Carré et C. Naud, Paris.

THIS series of clinical illustrations promises to be a momentous one and from the first fascicle we should judge that the authors are to be con-

gratulated on presenting to the medical profession a wonderful series of photographs.

The great advances which have come about in the art of reproduction have made it possible to illustrate the salient features of many disease types which heretofore have had to depend upon descriptive writings of a not-too-precise character. Modern methods have done away with these long and tedious word pictures and the possibilities of constructing such atlases as this is one of the achievements of modern day science.

To the neurologist more particularly will this first fascicle be most appealing. The illustrations show a large number of atrophic spinal conditions—Aran Duchenne's, Erb's, Leyden's, Moebius', etc.; types of neuromuscular disease are shown in six plates and some fifty-three figures. The limitations of a work of this kind are well recognized, but that this Atlas will prove of immense service in the science of diagnosis admits of but little question. When completed the work is to contain sixty-two plates with over four hundred illustrations. The price, 50 francs, is remarkably reasonable.

The Century Book for Mothers. By Leroy Milton Yale, M.D., and Gustav Pollak. The Century Co., New York.

For a book that goes to the point, that says the plainest facts in the simplest way, and that serves the purpose of a practical guide in the rearing of healthy children, we recommend "The Century Book for Mothers."

The nursery is the center of more superstition, more old-wives' tales, and more glittering generalities than any other social center. And as it is the starting-point of all society, it is most necessary that those that superintend its management, *viz.*, the mothers of the race, should have some training other than the haphazard combination of memories of their own childhood, and the experiences of their friends.

But there is little help for the practical mother in the vague psychic treatises that abound at present, dealing with the questions of prenatal influences and the flower-like unfolding of the mind under the kindergarten system, and there is untold harm lurking in the books of household medicine of the homeopathic variety, which excite a mother's ambitions to treat fevers and indigestion and save doctors' bills.

What a mother is constantly asking herself is, What shall she do with a child that grinds its teeth, that wets its bed, or that has a sore mouth? Or she is worried as to whether her child weighs enough or eats enough, or sleeps enough, hardly considering that these are subjects that concern the physician quite as much as the care of her child when it has measles or whooping-cough.

But because a physician seldom sees a child in health, and because the keeping of it so much depends on the mother, these authors have written a plain and sensible treatise on how to care for children in every detail of their daily life that pertains to their bodily health.

The use of drugs, except in cases of accidental poisoning, they have purposely refrained from discussing; but no item of hygienic value have they allowed to escape. Especially interesting and skilful in its treatment is that portion devoted to the perplexities of the average mother, as voiced for years in the columns of *Babyhood*. In the answers to these questions the authors lay low many fallacies, and promulgate many ideas based on common sense.

The family practitioner in glancing over the book cannot fail to wish that every mother in his clientèle had read and assimilated it. It would make his visits less discouraging, and his treatment more efficacious.

BOOKS RECEIVED.

The Medical News *acknowledges the receipt of the following new publications. Reviews of those possessing special interest for the readers of the* Medical News *will shortly appear.*

A Text-Book of Bacteriology. By Dr. George M. Sternberg. 8vo, 708 pages. Illustrated. Second Revised Edition. William Wood & Company, New York.

The Century Book for Mothers. A Practical Guide in the Rearing of Healthy Children. By Drs. L. M. Yale and G. Pollak. The Century Co., New York.

Human Physiology. By Dr. J. H. Raymond. Second Edition. 8vo, 668 pages. Illustrated. W. B. Saunders & Company, Philadelphia and London.

The Principles of Hygiene. By Dr. D. H. Bergey. 8vo, 495 pages. Illustrated. W. B. Saunders & Company, Philadelphia and London.

A Text-Book of Diseases of Women. By Dr. C. B. Penrose. Fourth Edition. 8vo, 539 pages. Illustrated. W. B. Saunders & Company, Philadelphia and London.

Modern Obstetrics: General and Operative. By Dr. W. A. N. Dorland. Second Edition. 8vo, 797 pages. Illustrated. W. B. Saunders & Company, Philadelphia and London.

Report of the Commissioner of Education for the Year 1899-1900. Vol. I., Washington, 1901.

A Text-Book of Embryology. By Dr. J. C. Heisler. Second Edition. 8vo, 405 pages. Illustrated. W. B. Saunders & Company, Philadelphia and London.

Text-Book of Nervous Diseases. By Dr. C. L. Dana. Fifth Edition. 8vo, 633 pages. Illustrated. William Wood and Company, New York.

The Protozoa. By Gary N. Calkins, Ph.D. 8vo, 347 pages. Illustrated. The Macmillan Company, New York.

A Text-Book of Medicine. By Dr. Adolf Strümpell. Third American Edition. 8vo, 1242 pages. Illustrated. D. Appleton and Company, New York.

A Text-Book of Physiological Chemistry. By Dr. Charles E. Simon. 8vo, 453 pages. Illustrated. Lea Brothers & Co., New York and Philadelphia.

A Treatise on Pharmacy. By Charles Caspari, Jr., Ph.G. Second Edition. 8vo, 776 pages. Illustrated. Lea Brothers & Co., New York and Philadelphia.

Dictionary of Philosophy and Psychology. Edited by J. Mark Baldwin, Ph.D. Vol. I. Quarto, 643 pages. The Macmillan Company, New York and London.

Pediatrics. The Hygienic and Medical Treatment of Children. By Dr. T. M. Rotch. Third Edition. 8vo, 1031 pages. Illustrated. J. B. Lippincott Company, Philadelphia and London.

Electricity in Medicine and Surgery, Including the X-Ray. By Dr. W. H. King. 8vo, 296 pages. Illustrated. Boericke & Runyon Co., New York.

Essentials of Obstetrics. By Dr. Charles Jewett. Demi 8vo, 386 pages. Illustrated. Lea Brothers & Co., New York and Philadelphia.

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LXXIX. NEW YORK, SATURDAY, NOVEMBER 30, 1901. NO. 22.

SPECIAL ARTICLE.

A TRIBUTE TO DR. T. GAILLARD THOMAS.

ON Thursday, November 21st, about 300 of New York's representative physicians did honor to Dr. T. Gaillard Thomas by celebrating his seventieth birthday at a dinner at Sherry's. Dr. Jas. McLane officiated as toastmaster in a very spirited and engaging manner and Dr. Thomas, Rev. Dr. Greer, Dr. Weir Mitchell of Philadelphia, Hon. Judge Howland, Dr. W. H. Welch of Baltimore and Dr. Geo. B. Shattuck of Boston responded to the toasts, each in inimitable manner, making the occasion a most enjoyable and inspiring one.

Dr. McLane, in presenting his congratulations to Dr. Thomas, and in response to the sentiment "I speak not this in estimation of what I think might be, but what I know," said: "This is no ordinary occasion. The gathering is not to commemorate any great political moment, nor yet to consider any national event. The physician deals with the events of private life and this gathering is a tribute to the resources of friendship. It is a matter of mutual felicitation that so representative a gathering have assembled. All kinds have come together; general practitioners, surgeons, specialists, teachers, from this city, from other cities and from other learned professions. It is an expression of affection and esteem for one long regarded as a friend, and as an honor to the medical profession for so many years."

Dr. McLane said that it would be impossible for him to respond to the letter of his toast for "all that he knew" was so much that time would not suffice for its recital. He was one of Dr. Thomas' oldest pupils and attended his first lectures in the College of Physicians and Surgeons. For over thirty-five years he had been associated with him in the school as student, in the faculty and in private work. He could speak of him as a teacher, as one with a most fluent gift of speech, and a most magnetic lecturer, and as a man whose evident sincerity, thorough manliness and marked personality made him beloved and added great fame to the institution in which he labored. Added to this were his remarkable hopefulness and cheerfulness. It was one of his highest characteristics that he should look on the bright side of all events and in his professional relations with his patients this attitude of the true physician was ever uppermost. Dr. Thomas had learned that precious art of knowing how to live and his high sense of honor and integrity had won for him the highest esteem. "Our hearts warm in the glow of an abiding faith." Dr. Thomas had reached the years of three score and ten and was, in the language of Oliver Wendell Holmes, a representative of that truth that "to be seventy years young was more hopeful and happy than to be forty years old."

"Our friend now wears white roses on his brow in the place of the red. May the vintage of his life grow sweeter and kindlier with every sun that sets and may his life continue to brighten those that come after."

Dr. Thomas, in response to the sentiment "Wisely silent to your own worth, and therefore t'were a sin for others to be so," said that he was made very happy by this large and enthusiastic gathering and by the many friendly glances. Even this, however, was not the full measure of the pleasure; it was, he said, the feeling that deep down in the heart of the profession there was the endorsement of the fellows of his kin. "You, my brother practitioners," he said, "have to-night sealed my career with the sign of approval. This is the highest joy." During one-half a century this approval had been the light of his course and the prize to be attained; without it, his life would have been as the Dead Sea fruit.

"This year," he continued, "is the proudest year of my life. About me I see the faces which were familiar in college halls and in hospital wards which have drawn from me the very best within me. * * * Down through the vista of fifty years I seem to see myself as a young man, entering this great city of Manhattan without a single acquaintance, and as I look forward from that moment the memory of many of New York's proudest ornaments in the medical profession comes into the eye of retrospect."

Dr. Thomas then spoke of Valentine Mott, who was then the sinecure of all eyes, the man at the top of the ladder. He spoke of Drs. J. W. Francis and the elder Delafield and Martyn Paine and then Willard Parker and later his contemporaries, Alonzo Clarke, W. Van Buren, T. M. Markoe, Baker, Austin Flint and J. T. Metcalfe; all had passed away save the last. He recalled those early years when there were gathered about ten young men, G. T. Elliot, Donahue, Otis, Green, Bunsen, Sands, Draper, Loomis, Budd and himself; all had run a glorious course and he alone remained. His half-century in the profession had seen great changes in medicine. In all the 2,300 years, from the days of the teachings of Hippocrates in the island of Cos, to the present, more progress had been made in this last fifty years than in all the 2,250 which had preceded it. He alluded to the great ideas that had come to prevail in modern medicine and which had done so much to revolutionize it as a science and so much to perfect it as an art. Virchow, he said, had just laid down the foundations in cellular pathology, on which the vast structure of modern medicine had been built. Anesthetics had banished pain; the X-ray had given eyes to the blind

and had illuminated the dark places as daylight; the invisible bacterial host had been routed and the death-rate from childbirth had been reduced almost to a minimum and was soon to be stamped out. All future plagues were no longer to be dreaded in the light of modern sanitary science. Gynecology had been revolutionized by Marion Syms, the science of medical thermometry had greatly elevated the art of diagnosis and the genius of a McBurney had robbed appendicitis of its dangers. Napoleon's one hundred days of terror had given place to fifty years of hope and freedom.

"The older I grow in medicine," said Dr. Thomas, "the stronger grows the conviction that

T. Gaillard Thomas, M.D., LL.D.

the medical profession exemplifies that 'great heart of the Saviour of the world.' The physician is the great benefactor of modern times and I hope soon to see the day when his position is more fully appreciated and that soon there may be represented in the Cabinet of the President of the United States a Secretary of Public Health.

"The memory of this night," he said in closing, "will lighten the future, and from the depths of my heart I thank you."

The Rev. Dr. Greer responded to the toast "Let me be privileged by my place and message to be a speaker free," and he was. In a very pleasing and playful manner he referred to his first meeting with Dr. Thomas, some thirteen years before. The doctor was then a leader of a private drill in the riding academy and he admired him because he rode so well and he then believed that he must be a good physician because one that rides a horse well can do nothing ill. This, he said, was the secret of his success. Dr. Thomas was a born rider, but he also had other accomplishments; he was a born orator and he knew of many a vacant diocese which he might fill most acceptably. He thought, however, that he would first ask him to preach to his benighted medical brethren, since they were so much in need of spiritual illumination. "To meet and find a *man,* was it not the greatest of all human charms? for back of all professions and all successes, whatever the field, his was the charm of a *man.*"

Dr. Weir Mitchell, in response to the toast "I'm told you write in public prints; if true, it's natural you should know a thing or two," repudiated, in playful manner, the sentiment, saying that it was not true that he wrote for the public prints and it was therefore not surprising if he knew very little. It was not the glory, he said, of having reached seventy years that was Dr. Thomas' this night; he himself had done that, and did not count it great, but it was the noble use that Dr. Thomas had made of that seventy years that endeared him to the hearts of his brethren.

In other lands, he said, great honors and distinctions were heaped upon men for various reasons; it our own country it was the destroyer of life, the man of the Army or the Navy, the wrecker of property and the former of gigantic industrial combinations, and the lawyer, who were chosen for places of honor and distinction. He did not quarrel, he said, that such were given, but for the medical man honors and distinctions there were none. He thought that this ought to be remedied and he hoped that this wrong would be righted. "We all to-night, however, grant greater honor and distinction to our guest for his faithfulness to all we hold just, wise and honorable in this profession." His was a life such as Sir Philip Sydney described: "A friend, intelligent and noble." Dr. Mitchell then spoke of the work of our profession; much of it was drudgery, unpaid and unremunerated labor; years of work in the hospital wards and rarely ever was it recognized by outward show of honor. The good Samaritan was certainly a doctor. He was the first of a long line which had continued to the present time to exercise the privilege of leading a useful life.

In more jocose vein Dr. Mitchell suggested that a Doctor's Trust would do much to wake the public from their lethargy. Just imagine, he said, the result of a doctors' strike. "I am very sorry, my dear madam, I cannot see you to-day, we are on a strike." He further spoke of the value of the body of specialists as moving features in the disposition of much wealth. Thousands of patients go to a given city for consulting purposes. The value in cash is enormous to the shopkeepers and hotels by reason of this very feature.

Of our guest, in conclusion, he said that he represented all that was dearest and best in our

profession and wished for him many more years of usefulness.

Judge Howland in response to the toast "I am one of those genial souls that will use the devil himself with courtesy," said that he unfortunately had been brought up in that puritanical school that considered all pleasures wicked and indigestible, but with the sight of so many physicians at dinner he felt somewhat reassured. He was more and more impressed, he said, with the charm of physicians individually, but collectively they were truly formidable, recalling to his mind the story of the Irish bride, who riding away on her wedding night, looks up into the beaming face of her husband, saying, "Don't you feel ashamed of yureself, for bein' so hansom?"

He wished, he said, to add his note of congratulation from the legal profession. He felt proud and distinguished to call Dr. Thomas his friend; it was in the eternal fitness of things that Dr. Thomas should have a birthday of his own, after assisting at so many others.

The physicians, he said, were the only profession that had maintained their place in the march of progress of the world. The law has crystallized into a series of eternal truths and was more concerned with forms than with new and vital facts; the clergy already had found, they thought, eternal truth and were chiefly concerned in modifying their sentences of description, making it more poetically attractive, but the physician had no such limitations; the half-truths of yesterday were cast aside for the fuller truths of to-day. Progress was their keynote and their work always remained undone. Dr. Thomas was one whose work, even now, was never done; he had written his name high in the annals of the profession as second to none.

Dr. Wm. H. Welch spoke to the response "And, indeed, I believe no man ever taught better; each sentence hangs perfectly poised to a letter," and gave a short résumé of Dr. Thomas' career which as a teacher has given him a world-wide fame. It was in 1856 that he began studying in New York and was resident physician in Bellevue. He soon formed a quiz class in New York, the second of its kind, which had a marked success and which first brought out Dr. Thomas' unusual capacity as a teacher. In the United States, he said, it was a difficult thing to develop a gift of this kind or to acquire a reputation therefrom; the *privat docent* system of the German universities was much better in this regard, but the quiz system made a substitute. It has its abuses but also its useful purposes; with Dr. Thomas it soon brought him to the front and he became an adjunct lecturer in the university and later physician to Bellevue Hospital, where he was one of the first to bring about real advances in the science of exact diagnosis. Direct observation was the keynote of his method.

He was soon associated with Dr. J. T. Metcalfe as professor of obstetrics in the College of Physicians and Surgeons, and became, later, professor of gynecology in the same college. He rapidly acquired a great reputation and wide fame which is the proud possession, not of the alma mater of the College of Physicians and Surgeons alone, but of the medical profession of America. His style of lecturing was marked by gracefulness and marked felicity of expression, combined with a warm enthusiasm for practical bedside work. His was the spirit of personal inquiry and of personal investigation, sound gospel and still needed. He spoke not only by his lectures, but also by his work on gynecology, which has been published in six editions and 60,000 copies sold. He molded the ideas of a generation in gynecology more than any other teacher of this country. "There are many to call him master. He has numberless friends and admirers, and his colleagues appreciate the lovable character of the man, who has the best and the highest ideals."

Dr. Geo. B. Shattuck of Boston responded to the sentiment "No men can be more amiable than men of sense, who are doctors." He recalled the time when Dr. Holmes was to relinquish the chair of anatomy at Harvard University and referred to the address that Dr. Thomas gave on that occasion, when he said that "Dr. Holmes had taught them it is an important lesson that the man who became distinguished as a physician need not rest there—need not remain a man of one view or of one idea. Dr. Holmes had bridged over that chasm which from time immemorial has existed between the medical profession and the world, had done much to bring the profession of medicine into a pleasant, agreeable combat with society at large." The pupil had learned the lesson from his master, for Dr. Thomas had certainly done much to bring the public into closer harmony with medical thought. He spoke of his association with Dr. Metcalfe, saying that they both came from southern climes, being born near enough to the sun to ripen well, and they were both brought out by the atmosphere of New York.

Dr. Shattuck then spoke of other medical men who had not been men of one idea. The elevated railroad in New York City had been inspired by a medical man. The rapid-fire gun was an invention of a medical man and the saving of the great Northwest to the United States was the outcome of the efforts of a member of the medical profession.

Speaking more particularly on his toast "Why are medical men amiable? Why are they sought for?" he said it was because they were companionable men. They studied mankind at first hand and grappled with the material sides of existence, seeing much that is noble and much that is the reverse. All good and strongly-balanced minds were drawn to the study of practical problems and the medical man believes that laws regulate mankind. Many of these he knows, others he guesses at, and of still others he is ignorant—he rejoices, but is not exultant nor boastful, nor does he shrink—his watchword, 'Though I perish, seed is sown.'"

ORIGINAL ARTICLES.

COURVOISIER'S LAW.

BY RICHARD C. CABOT, M.D.,
OF BOSTON, MASS.

IN 1890 Courvoisier[1] analyzed a large number of cases of diseases of the biliary tract, recording all kinds of statistics regarding them. When tabulating cases with reference to the conditions of enlargement of the gall-bladder, he was greatly surprised to find that when the common bile-duct is obstructed, enlargement of the gall-bladder by no means always follows. In cases of obstruction due to gall-stones, the gall-bladder was rarely enlarged, while if the obstruction were due to any cause other than gall-stones, the gall-bladder was almost invariably enlarged. Thus, out of 187 cases of obstruction of the common duct, there were 87 due to stones. In 70 of these 87 cases (or 80.4 per cent.) the gall-bladder was found atrophied, while in only 17 cases was it dilated. On the other hand, out of 100 cases in which the obstruction was due to causes other than stone, 92 were associated with dilatation of the gall-bladder, while in only 8 cases was the gall-bladder small or normal.

So far Courvoisier was judging wholly from the analysis of literature, but in looking over his own cases he found that the figures were equally striking. Out of 17 cases of obstruction of the common duct by a gall-stone, there were but four with enlargement of the gall-bladder, while out of 18 cases in which the obstruction was due to causes other than stone, 16 were associated with enlargement of the gall-bladder. Perhaps as short a method as any for stating Courvoisier's law is as follows:

When the common duct is obstructed by a stone, dilatation of the gall-bladder is rare. When the common duct is obstructed by other causes, dilatation of the gall-bladder is common.

Two years later Mayo Robson, the well-known English surgeon, independently came to the same conclusion. In his pamphlet on "Gall-Stones and Their Treatment" he stated the law as follows: "Jaundice with distended gall-bladder is presumptive evidence in favor of malignant disease, but jaundice without distended gall-bladder favors the diagnosis of cholelithiasis." Mr. Robson does not seem to be aware that Courvoisier deserves the credit for this law, but of its truth he has no doubt. Among the cases recorded in his recent book on diseases of the gall-bladder and biliary passages, there are 38 in which a definite statement is made regarding the size of the gall-bladder in cases of obstruction of the common duct. Thirty-five or 92 per cent. of these cases go to corroborate Courvoisier's rule. Out of 23 cases of obstruction of the common duct by gall-stones, 21 were associated with small gall-bladder and only 2 with large gall-bladder. Out of 15 cases of obstruction by cancer, together with 2 of obstruction of the cicatrix, only 1, a case of cancer, failed to show a dilatation of the gall-bladder. In 92 per cent. of these cases, therefore, Courvoisier's rule is borne out. Ecklin (quoted by Osler) finds that out of 172 cases of stone in the common duct, only 28 or 16 per cent. were accounted for by dilated gall-bladder, while out of 139 cases of occlusion of the common duct by causes other than stone, 121, or 87 per cent. showed dilatation of the gall-bladder.

Kehr[2] whose experience includes 409 gall-stone operations is very explicit on the subject: "In obstruction of the common duct by a stone the gall-bladder is usually small and not to be felt; in obstruction by tumor (cancer) it is usually to be felt as a large elastic tumor under the right ribs."

This rule, therefore, may be taken as tolerably well established by the statistics already quoted, especially as there are, so far as I am aware, no contradictory statistics. Naunyn in his treatise on cholelithiasis, 1896, treats the rule as a well-established one and makes the absence of dilatation of the gall-bladder one of the main points in the diagnosis of stone in the common duct. But curiously enough Courvoisier's rule seems to have been very slow in penetrating the minds of American physicians and surgeons. This I can readily show by a series of quotations from the more recent American treatises on surgery and internal medicine.

In the American Text-Book of Surgery we find the following statement: "When a gall-stone is arrested in the common duct there is obstruction to the outflow of bile and the gall-bladder becomes enlarged and may be felt as a rounded pear-shaped tumor." In Park's Surgery (article on the surgery of the abdominal cavity by Maurice H. Richardson and Farrar Cobb) this statement occurs: "Impaction of a stone in the common duct usually causes marked dilatation of the gall-bladder." In Dennis' Surgery, edition of 1896, article by Abbé, there is no reference whatever to the facts on which Courvoisier's law rests. The same is true of the article by J. W. Elliot in the International Text-Book of Surgery. Among writers on the practice of medicine, Osler in his last edition, 1898, makes a very clear and pointed reference to the truth noted by Courvoisier. But in the edition of 1895 the same facts are apparently not recognized, or at any rate are not made clear. In Tyson's Practice, 1896, p. 334, the author says: "If the gall-bladder is dilated and can be felt at the edge of the liver there is probably obstruction of the common duct, and if there is pain and tenderness, the obstructive agent is probably a gall-stone." Wood & Fitz's Practice of Medicine and Pepper's American Text-Book, 1894, make no reference to the subject.

In view, therefore, of the fact that most American writers on medical or surgical aspects of diseases of the gall-bladder, either make no ref-

[1] Beiträge zur Pathologie u. Chirurgie der Gallenwegen, Leipzig, 1890.

[2] Kehr. Gall-Stone Disease, p. 91.

erence to the facts emphasized by Courvoisier, or, as in the case of the articles by Tyson and Richardson above quoted, make a statement directly contradicting that which has found general acceptance in England and on the Continent, it has seemed to me worth while to tabulate from the records in the Massachusetts Hospital all the accessible cases bearing upon this point. This I have been enabled to do through the kindness of Dr. J. H. Wright, of the Pathological Laboratory and of the visiting surgeons of the hospital. The result of my study has been to confirm far beyond my expectations the truth of Courvoisier's rule.

My material consists of 30 autopsies and 56 cases which did not come to an autopsy, but in which the condition of the gall-bladder and of the common bile-duct was seen and felt at operation. Among these 86 cases were 57 of obstruction of the common duct by gall-stones, and 29 in which the obstruction was due to other causes, almost invariably cancer of the pancreas. Out of the whole 86 cases there were but 4 which violate Courvoisier's rule. The gall-bladder was atrophied in 47 cases of obstruction by stone, normal in 8 and enlarged in 2. In one of these 2 cases the record states that the gall-bladder was "moderately distended," but gives no figures regarding its size. In the other cases, 6 ounces of bile were evacuated from the distended gall-bladder. These 2 cases form the only exceptions to Courvoisier's rule out of the total of 57 cases of stone in the common duct.

On the other hand, out of 29 cases of obstruction by cancer of the pancreas or other cause not stone, there were but two in which dilatation of the gall-bladder was *not* found. In one of these the gall-bladder was empty; in the other it was contracted around three gall-stones. With the exception of these 4 cases which constitute only 5 per cent. of the total number examined, every record of the Massachusetts Hospital series in which definite statements are to be found concerning the points at issue goes to confirm Courvoisier's rule.

The explanation of the difference in the behavior of the gall-bladder following the obstruction of the common bile-duct by stone on the one hand or by other causes on the other is considered by Courvoisier to be the following:

In the great majority of cases when a stone blocks the common bile-duct, there are or have been stones in the gall-bladder itself. The irritation thus produced has resulted in chronic inflammation with thickening of the wall of the gall-bladder, such that the gall-bladder is no longer distensible. In the great majority of cases it is contracted or atrophied. On the other hand, in many of the cases in which the common duct is blocked by cancer of the pancreas or other cause outside the ducts, the walls of the bladder are thin and easily distensible, so that the backing up of bile behind the obstruction readily distends them. This explanation is supplemented by another offered by Fenger in the *American Journal of Medical Sciences* for February and March, 1896. Fenger finds that the stone is not always firmly wedged into the duct, but may be loose or "floating." Hence he conceives that in many cases the stone in the common duct has a sort of ball-valve action, whereby the obstruction to the bile is not complete for any length of time. Mayo Robson believes that both these explanations are correct and that each accounts for some cases. Of course, if the common duct becomes blocked by cancer when the gall-bladder already contains and has been irritated by stones, we may have the association of non-lithogenous obstruction and a small gall-bladder. This was the case in one of those tabulated above from the records of the Massachusetts General Hospital.

Now what is the use of this law? Quite obviously, I think, it is of value in the diagnosis of cases of chronic jaundice, with or without enlargement of the gall-bladder. Excluding those cases of dilated gall-bladder due to stone in the cystic duct and also those of acute cholecystitis in which we rarely have jaundice, we find a group of cases in which the most important signs are chronic jaundice, more or less intermittent, and the presence or absence of enlargement of the gall-bladder.

Now if it is true that within this group we can distinguish the curable from the incurable, the operable from the inoperable, the lithogenous from the non-lithogenous cases, chiefly or mainly by observing the indications furnished by Courvoisier's rule, the importance of that rule is not open to dispute. The statistics that I have quoted seem to me to warrant the conviction that this rule can be relied upon to an extent rarely possible in a matter so uncertain as physical diagnosis.[1]

REPORT OF A CASE OF DIAPHRAGMATIC HERNIA[1]

BY H. D. HOWE, M.D.,
OF HAMPTON, VA.

ON October 10, 1900, I was summoned hurriedly to see A. W., who, while "scorching" on his wheel with head bowed low, ran full speed into a cart coming in the opposite direction. The involuntary effort to check himself caused him to receive the full force of the blow against the end of the shaft just below the left breast, instead of on his head. He was hurriedly conveyed to the Hospital, where I saw him.

At this time all the symptoms of shock were manifest and it required the usual remedies quite vigorously applied to cause reaction. There was a contusion, with considerable swelling, about three inches in diameter, the center of which was over the sixth interspace in the left anterior axillary line. Respiration was shallow on this side, but the respiratory murmur was clear and distinct, and the heart's action, while feeble at first from shock, soon became regular and fairly strong. There was no vomiting nor cough and the pain was of a stabbing nature,

[1] From advance sheets St. Paul Medical Journal.

made more deep by inspiration. Although no fracture of a rib could be detected, I strapped the left chest from lower margin of the ribs well above the site of injury. This gave considerable relief. Aside from a small superficial slough at the point of injury, which healed very quickly after removing the straps on the second day, there was nothing interesting in his rapid convalescence. There was never any vomiting or intestinal trouble. The only respiratory change was the lack of full expansion over the base of left chest. At the end of six days the patient was discharged and resumed his duties and studies in a military school.

From this time until the patient's admission on May 17, 1901—a period of over seven months—he never once reported for sick call and was able to engage in various athletic sports, although his companions state he was never as active as before his injury. The recent trouble began after violent exertion in a jumping match, from which, after a few trials, he had to withdraw on account of pain in his chest. On admission to the Hospital the following morning he complained of nausea and a dull pain up and down the lower half of the sternum. Physical examination revealed a decrease in the respiratory movement of the lower half of the left chest, with distant breath sound. The heart was displaced to the right and upward. Its sounds were normal. The abdomen was somewhat scaphoid, but nothing abnormal was detected by palpation. The bowels were obstinately constipated. He was given small amounts of peptonized milk and divided doses of calomel and soda ordered. This was all vomited and rectal feeding was begun the following day. High enemas of various kinds had no effect on the constipation, which was constant until death. There was at no time any abdominal tenderness. Vomiting, which had been persistent, was relieved by gastric lavage. This gave so much relief that the patient requested its continuance and the tube was passed each day until his death. The stomach would hold only a small amount before retching would occur, yet there is no doubt of the tube having entered the stomach because of the large amount of inky-black contents washed out. Owing to the extreme weakness and irritability of the patient and the inability to change his position, the stomach tube was of little diagnostic aid as to the position of the viscus.

For a period of ten days from admission the patient was nourished almost entirely by enema. Emaciation had become extreme. The question of exploratory laparotomy for the location and possible removal of the obstruction which it was thought existed at the pylorus was considered and decided negatively, as the patient's condition was extremely critical the last five days of his illness and it was feared even an exploratory operation would be immediately fatal. On the tenth day, during a sudden syncope, which followed his usual gastric lavage, I was able to detect a most beautiful succussion splash and tinkle over the left chest as high as the fourth interspace. The coin test was absent. Above the fourth interspace the breath sounds were clear and regular though rapid. The patient died in a few hours. During the entire period of his sojourn in the Hospital he was able to rest only in a sitting posture and would frequently jump out of bed, if the attendant's back was turned, claiming that he obtained greater ease by standing. The facial expression was that of a most hopeless and pitiful sufferer.

The postmortem was made six hours after death. Rigor mortis was extreme, emaciation considerable. The stomach, transverse colon, upper part of descending colon and fully one-half of the great omentum were found in the left chest cavity. The rupture in the diaphragm was one and a half by one and a half inches, and was near the center of the muscular portion, one inch to the left of the esophageal opening. The edges of the hernial opening were indurated and rolled upward in the thoracic cavity. The heart was displaced to the right and upward. The lung was crowded up above the fourth interspace, but was normal otherwise. The stomach was somewhat dilated and contained about eighteen ounces of inky fluid. The hernia was not strangulated and there was no inflammatory condition of the stomach or intestines. At a point near the junction with the colon, the omentum was strongly adherent to the pleura in the sixth interspace—the site of the contusion of the chest. There was an almost entire absence of the intercostal muscles at the point of the old injury, but no fracture of the rib was perceptible.

SOME OBSERVATIONS, GENERAL AND TECHNICAL, MADE AT THE CRAIG COLONY[1]

BY SMITH ELY JELLIFFE, M.D., PH.D.,
OF NEW YORK;
CLINICAL ASSISTANT, DEPARTMENT OF NEUROLOGY, VANDERBILT CLINIC, COLUMBIA UNIVERSITY; VISITING NEUROLOGIST, CITY HOSPITAL.

IN a visit of three months made to Craig Colony in 1899, for the purpose of studying the methods of treatment that have been so successful there, I was particularly impressed with the fact that the recognized presence of epilepsy did more to hide it than anything else. The most startling thing that the visitor to Craig Colony notices is not the prevalence of epileptic fits, but the absence of them.

In driving through the broad, rolling valley, with its winding ravine, one comes upon groups of men hoeing, making hay, digging and draining ditches, gathering and carting vegetables. In the orchards women are picking up apples and in the gardens weeding the beds. There is a tranquil, thrifty air to the scene, the rich loam of the soil, and the luxuriant aspect of the potato and tomato and cabbage fields, with the number

[1] From advance sheets of The Medical Report of Craig Colony.

of coloners at each task, which lead one to believe that he is on the lands of some well-to-do farmer. The impression is still deepened as one nears the great barns and poultry houses and sees more men leisurely working.

A little further and one is in a municipal center with the hospital, school-house, church and administration buildings, at the entrance to a village green with rows of cottages on either side. Glimpses of games, tennis, baseball, swings, a few bicycles, and groups of children under the trees, make the scene look like some Utopian village where everybody keeps his lawn in order and has good times. But with the exception of a few men in black-visored caps and a few women with white aprons, every man, woman and child in sight is an epileptic and might at any time need the care of one of the male or female nurses who assist and direct the workers.

In any problem, a common factor may be struck out and leave the relations of the component parts the same as before, and the factor of epilepsy, by virtue of its commonness, seems to be eliminated from the Colony life; or, rather, where in a normal village an attack would create a sense of horror and excitement, here it is passed over and barely noticed. The attendants are so quick to lay a patient down on the pillow that is always present even in the fields, and cover him up, that his fellow workers are scarcely aware of his seizure.

This method of eliminating all excitement and notice from the epileptic, seems to remove the dread and terror of the attacks, and has a perceptible effect in diminishing their frequency, as may be seen in many cases where improvement begins from the day of entrance, apparently from no other reason than that there was nothing to fear of danger, obloquy, or excitement in connection with a seizure.

The general method of treatment at the Colony as seen by an observer in its broadest lines seems to lie in whatever will take the mind of the patient from himself and his abnormal state and develop in him the normal qualities of manhood that have almost invariably been neglected in his life. In other words, it is a process of training to change the man from an idle, introspective invalid to a busy, useful, altruistic member of the community.

The most potent factors in this life are good food, open air, labor and sociability. But it is in the wise personal application of these factors that one sees the genius stroke that works the cure. A convict may have these same elements in serving out his term, but the epileptic at Craig Colony has them scientifically combined. He is made the subject of personal study, his heredity, his antecedents, his education, his social standing, are all taken into consideration, and he is given work that is congenial to him.

Many who come there do not know how to work. From childhood they have never been allowed to use a tool for fear of cutting themselves; to wash a dish for fear of breaking it; or to go to school for fear of creating a disturbance; therefore they live a life of idle stupidity, waiting for the next fit. Such persons at the Colony have Kindergarten and Sloyd training, and with the interest that comes with increasing deftness and occupation, they almost invariably improve and reach the point where they can engage in some of the Colony's real work.

The moral and mental effect of progressive work on the health of the epileptic has been shown in some who have never learned a trade because no one would employ them. They have here been given an opportunity to learn brick-making, printing, gardening, fine laundry work, sewing, shoemaking; in fact, almost any trade of normal village life; and such has been the effect of the combination of an interested mind and busy hands that several have gone away from the Colony, not only cured, but equipped to earn their living.

I learned with interest that, although the amount of work that each patient could do varied with the individual, the average was about one-third that of a normal man's labor.

The tact and patience of the nurse-assistants and teachers are at the basis of most of the improvement, because the epileptic has almost invariably been brought up in idleness, and labor presents itself to him in any light but that of a means of cure. It must be made interesting, it must be varied, it must be done with frequent intermissions for rest, it must be suggested as a favor, rather than a duty, and yet for the sake of the community's support, it must be done well.

It is sometimes weeks, even months, before a man finds his niche. He tries his unskilled hands at gardening, poultry raising, milking, shoepolishing, and perhaps finds his congenial occupation in waiting on table, or tending store. And when a man does find a congenial occupation, he generally improves in health and has less frequent attacks as his interest increases, and thereby repays by the value of his labor the effort made for him.

The cultivation of the social side of the epileptic appears to be as difficult as it is beneficial. Partly as a result of social ostracism and partly as a symptom of his disease, the epileptic is nervous, excitable and irritable. He is generally hard to live with in any circumstance, and in the aggregate he presents a very difficult problem that the Colony has, however, met with great success.

The social privileges that the patients have hitherto been debarred from are not only offered, but they are taught to enjoy themselves. The nurses teach the girls to dance, and every evening waltz music is heard. The young men are taught to play baseball, and the Saturday afternoon audience is taught to enthuse over the game. Picnics and games are made as mirthful as is possible to those that do not know mirth; but gradually the spirit of enjoyment serves to drive away the despondent apathy, and the actual en-

joyment of play saves the outbreak of temper which excites the attacks.

That such elaborated schemes of work, combined with amusement, are at the basis of the improvement observed in the Colony's patients, can be proved by noting the reverse side as seen from the experience of the lecturers and assistants. As an example: The master of the brickyard stated that on bright days when each man was busy hauling clay, puddling, pressing or piling bricks, according to his degree of efficiency, there would hardly be a fit among them; but let the day's work be interrupted by showers and the men obliged to congregate in close quarters for an hour in the shed, with leisure to grumble, and quarrel, and sulk, there would be fifteen or twenty attacks in that time.

In the same way, the matron of one of the women's houses stated that if each inmate did her task under pleasant authority, and the day was quiet and well ordered, with some pleasant recreation, the seizures were few and far between; but any scene or excitement that broke the even tenor of the day would be followed by an unusually large number of attacks.

Undoubtedly the mental attitude plays an important part in the frequency of the epileptic attacks, and it is interesting to observe how thoroughly this is impressed upon the minds of those in charge and all their assistants, so that their efforts and skill are all directed to keeping the patients' minds healthfully occupied and happily diverted; thus the evil effect of one person in an attack setting a number of others off only happens occasionally, and then serves as an illustration of how forceful is untoward suggestion and a perverted mental attitude in epilepsy.

One of the chief points of interest to a physician of city practice, where he sees his patients only at intervals, and then in the midst of their own peculiar social surroundings, is the complete revolutionizing of the ordinary haphazard life of competition into the healthful life of a village sanitarium, yet preserving enough of the community spirit to in part support life.

The problems of the resident physicians and superintendent include the civic problems of the mayor of a city, the trustees of a school, the deacons of a church; they require good practical grip on the laws of supply and demand, to feed a thousand people from the products of the soil and stock, and to turn the surplus to money value. They require an immense capacity for executive detail, and a perennial supply of tact to guide a village full of peculiar people into ways of health and usefulness, and at the same time keep a steady eye on the State appropriation and approbation.

Added to all this is the elaborate detail work of a purely medical nature, the study of peculiar cases, the unearthing of causes and experiments on various diet regimens, and the newest methods of treatment that the study of this branch of neurology is constantly suggesting.

My interest in Craig Colony as a social, philanthropic and medical institution increased daily as I perceived its far-reaching effect. Every patient there represents as many homes in the State, and perhaps five times as many working people relieved of the support of a non-productive member. It means the freedom for active labor of at least one member of the family who would otherwise be obliged to care for the helpless one. It means the economic use and development of all the labor that the epileptic is giving toward his own support. It means the greatest opportunity that any country has hitherto had for studying the disease in its hereditary, causative and therapeutic aspects.

And, by no means least, it makes life reasonable and bearable for most, while for others it strengthens and cures; so that, as a physician whose experience has been limited to city clinics and private practice, I hardly know which to admire most—the breadth of mind that evolved Craig Colony, or the conscientious, wise and energetic administration of its affairs.

RECENT EPOCH-MAKING IN MEDICINE—ANNUAL ORATION DELIVERED BEFORE MICHIGAN STATE MEDICAL SOCIETY.

BY SAMUEL BELL, M.D.,

OF DETROIT, MICH.;

PRESIDENT OF THE WAYNE COUNTY MEDICAL SOCIETY; MEDICAL SUPERINTENDENT OF LAKEWOOD PRIVATE HOSPITAL FOR MENTAL AND NERVOUS DISEASES.

AT a meeting of the British Pathological Society of London, April 6, 1875, the "germ theory" of disease was first formally introduced for discussion; the discussions were very animated and earnest and were continued at subsequent meetings. This conference was attended by distinguished medical men, some of whom were profoundly impressed by the arguments brought forward in favor of the "germ theory." The co-existence of bacteria and contagious disease was admitted, but Dr. Bastian, one of the most prominent speakers, contended that they were pathological products spontaneously generated in the body after it had been rendered diseased by real contagion. The grouping of the ultimate particles of matter to form living organisms was considered by the speaker to be an operation as little requiring the action of antecedent life as their grouping to form any of the less complex chemical compounds.

Status of Opinion.—Prior to this meeting in London, Henle in 1840, after mature deliberation, weighing all the evidence that had been collected, determined that the cause of infectious diseases was to be found in minute living organisms or fungi. Henle may be truly looked upon as the true propounder of the "germ theory" of disease. He not only collected facts but formulated opinions and investigated the subject with such great ability that Koch in after years promulgated the same opinions determining the relationship between bacteria and disease. In 1862, Pasteur published a paper on the "Organized Corpuscle Existing in the Atmosphere," in which he demonstrated that many of the floating particles

which he had collected from the atmosphere of his laboratory were organized bodies, and if these were placed in sterile infusions, abundant crops of micro-organisms were obtained; and by subsequent more exact methods and experiments by himself and others, showed clearly that the cause which imparted life to his infusions came from the air. Listerism originated in 1875, and when Koch published his famous work on the Wund-infectionskrankheiten (traumatic infectious diseases), in 1878, it spread slowly at first, but surely to all departments of medicine and surgery.

From time to time as the need was realized, men of genius have provided devices and instruments of material aid in their work; some of these have made possible subsequent discoveries. Among them may be mentioned the improvement of the compound microscope, the use of sterilized culture fluids by Pasteur, the introduction of solid culture-media and the isolation methods by Koch, the use of the cotton plug by Schroeder and Van Dusch and the introduction of the anilin dyes by Weigert. It is an interesting fact to note that after the discovery of the anthrax bacillus by Pollender and Davaine in 1849 there was a prolonged period during which no important discoveries of pathological organisms were made, but during this period important methods of technic were elaborated. This was again followed by a period during which important additions followed each other in rapid succession. In 1873 Obermeier discovered the Spirillum Obermeieri of relapsing fever. In 1879 Hansen made the announcement of the discovery of bacilli in the cells of leprous nodules. During the same year Neisser discovered the specific gonococcus of gonorrhea. In 1880 the typhoid bacillus was first observed by Eberth and independently by Koch. During the same year Pasteur published his work on "Chicken-cholera" and the pneumococcus was described by Sternberg. It was in the year 1882 that Koch made himself immortal by announcing to the world the discovery of the tubercle bacillus, and in 1882 Pasteur published a work on "Rouget du Porc" and Löffler and Schutz reported the discovery of the bacillus of glanders. In 1884 Koch announced the discovery of the "comma bacillus," the cause of cholera, and at about the same time Löffler discovered the diphtheria bacillus, and before the end of the same year Nicolaier the tetanus bacillus. In 1892 Cannon and Pfeiffer discovered the bacillus of influenza. In 1894 Yersin and Kitasato independently isolated the bacillus causing the bubonic plague. In 1894 Sanarelli discovered the bacillus icteroides, supposed to be the bacillus of yellow fever.

During the last quarter of a century the science of bacteriology has made triumphant strides, revolutionizing our ideas, especially in relation to infectious diseases, their etiology, diagnosis and treatment. Among the diseases upon which information has been of greatest value are tuberculosis, diphtheria, tetanus, bubonic plague, etc.

In 1875 there were few scientific men who had accepted the germ theory. The great majority, adhering to the doctrine of spontaneous generation, believed with Billroth that the presence of fungi where decomposition was in progress was an accident result of their universal distribution, or, being more conservative, that their presence in putrid wounds was produced spontaneously, or in unquestionable artificial media.

Diphtheria Antitoxin Treatment.—McFarland says that on his part, all possible skepticism of the specificity of the bacillus of Löffler was dispelled by an accidental infection that kept him housed for three weeks during the busiest season of the year. Without having been exposed to any known contagion from diphtheria, while experimenting in the laboratory, a portion of a living virulent culture of the diphtheria bacillus was drawn into a pipette and accidentally entered his throat. Through carelessness no precautions were taken and as a result of the accident, he says, "Two days later my throat was full of typical pseudo-membrane, which public and private examination showed contained the Klebs-Löffler bacillus."

Prof. Welch of Johns Hopkins Hospital has perhaps furnished the most reliable, as well as the largest, statistics upon the result of the antitoxin treatment of diphtheria. His report, excluding every possible error of calculation, shows an apparent reduction of case mortality of 55.8 per cent. Another very important point shown by Welch, illustrating the importance of early treatment, is that 1,115 cases of diphtheria treatment in the first three days of the disease yielded a fatality of 8.5 per cent. as against 546 cases injected with antitoxin after the third day yielded a fatality of 27.8 per cent. Thus was established the fact that after the toxin had set up destructive organic lesions in the various organs of the body, no amount of neutralization will restore the integrity of the parts; consequently, antitoxins must fail in these cases. The great necessity for early treatment was demonstrated.

Syphilis.—In 1884 and 1885 Lustgarten published a method for staining bacilli which he found in syphilitic tissue and assumed to be the cause of the disease. The most recent research upon the bacteria of syphilis is that of Van Niessen, who claims to have cultivated a syphilis bacillus from the blood of a few cases. In Van Niessen's inoculation experiments there were observed as evidence of the specificity of the organism discovered by him: (1) Abortion in pregnant female rabbits; (2) extra-genital primary lesions on the ears of inoculated rabbits in the form of nodes; (3) secondary ulcer and tumor formations and irregular lesions. The researches of others have up to the present time failed to confirm the above results, consequently the specific bacillus has not been fully established.

Bubonic Plague.—Considering our increased possessions in the Eastern Hemisphere, the importance of the recognition of this most dreaded of all diseases can be appreciated when our United States Marine Hospital Service reports the introduction of the plague for the first time

in the Western Hemisphere. Its appearance in Santos, Brazil, in October, 1899, marks an epoch in plague literature, as furnishing the very first recorded instance of the disease in the Western Continent. During November of the same year the disease was carried to New York by a British steamship. During the latter part of December, 1899, the plague made its appearance in Honolulu, and its appearance in California is so recent that the mere mention is sufficient.

This disease furnished a striking illustration of the scientific advance of modern medicine. It was not until 1894 that positive knowledge of its true nature became known. Prior to that time, all through the centuries, the subject had been enveloped in darkness, and there has been the same groping after facts, the same unsuccessful search for the true cause, the same struggle in ignorance against its ravages on the part of the physicians, sanitarians and public officials as has marked the history of that other dread disease, cholera, now also robbed of its terror by science. Now, the cause of the plague, its method of propagation and the means to prevent its spread, are matters of scientific knowledge. To Pasteur and his contemporary, Koch, is due the credit for the possibility of this discovery by their establishment of bacteriology as a science, and to a Japanese physician, Dr. Kitasato, and to the French Dr. Yersin we are indebted for the discovery itself.

The fact is now established that the plague is an infectious disease caused by a specific bacillus, discovered by Drs. Yersin and Kitasato. The anti-pest serum of Yersin and Roux has been tested and gratifying results obtained, and also from the Haffkine prophylactic serum, the latter for the prevention and the former for its effects upon the bubonic poison, neutralizing the same in the system. The French Commission, who have recently investigated the efficacy of the anti-pest serum in Portugal, report that in cases treated with the serum the mortality was 14 per cent., and in those without it 70 per cent. In a recent lecture given by Roux at the Pasteur Institute, a striking illustration is given of the efficacy of the treatment of the disease by the Yersin serum. "The Bombay manager of the local branch of the Credit Lyonnaise resided with his wife, children and a numerous retinue of native servants, in a dwelling in an infected portion of the city. His little daughter was stricken with the pest in a virulent form; was treated with the serum and made rapid and uneventful recovery. As a precautionary measure the whole family were subjected to inoculation and the same measure of treatment was offered to the native domestics. Some accepted and escaped infection, while six who declined on the ground of religious scruples were all stricken and five died. It seems that a more crucial test could not have been devised or a more triumphant vindication obtained."

The *British Medical Journal* reports the result of the Haffkine prophylactic in the villages of Bombay, showing the reduction of the mortality of those inoculated as 80 per cent.

The work of the recent Federal Commission in establishing the disputed fact that the plague existed in California was a signal triumph for modern scientific achievement.

Typhoid Fever.—Clinical value of the serum diagnosis. In 1896 Widal and Grunbaum, working independently, discovered that when blood-serum from typhoid-fever patients is added to cultures of the typhoid bacillus a definite reactive phenomenon occurs. This phenomenon is known as the "Widal reaction," and consists in complete loss of the motion of the micro-organisms, so that they gather into clusters or groups—agglutination. The Widal test was applied to 230 cases of typhoid fever among soldiers who had enlisted in the Spanish-American War and who were treated in the Medico-Chirurgical Hospital. Of these, 219 reacted positively, or 95.64 per cent. of the total number examined. The results obtained in Osler's wards in the Johns Hopkins Hospital by Block and Gwyn up to November, 1898, show that in 151 cases the reaction was present in 144. Granting the precision of method of serum diagnosis, it is doubtless of great diagnostic importance. As shown by the statistics given, the reaction failed to develop in only 4.5 per cent. out of the total of 2,393 cases of typhoid fever. And it is probable that this small percentage of failures would be reduced if the test (when negative at the first examination) were repeated every day or two until convalescence is fully established.

Stomach.—During the last ten years phenomenal advancement has been made in the diagnosis and treatment of disease of the stomach: The gyromele has been invented; the gastrodiaphane perfected; the perfect gastric electrode invented; the gastric bucket invented; X-ray pictures of stomach made; a quantity of lavage apparatus devised; gastroscopy made fairly practicable, and a number of gastric operative procedures devised.

Scope and Clinical Value of Blood-Examination.—Hematology being a comparatively new study and sufficient time not having supervened since the beginning of blood-examination for clinical diagnosis, the limit of usefulness has not yet been determined. Thus far the results have been very uncertain, disappointment sometimes resulting when the opposite was expected and again much light has been thrown when least anticipated. There are not as many diseases as we have fingers in which the diagnosis is made by blood-examination alone, but there are many diseases in which blood-examination is a decided help; not definite signs, but links in a chain of evidence are what we expect and get. On the whole, blood-examination is not second in results to examination of the urine. Both methods give definite results in a few diseases, and sidelights in many obscure conditions, even if the examination is negative. It has one very decided advantage, *viz.*, that the examination can be

made during the life of the patient, and like all methods of physical examination, if there is any cause, such as insanity, stupidity or unconsciousness, preventing the intelligent communication with patient, and in all febrile diseases much light can be given.

The Rôle of the Mosquito in Fevers.—It is now conceded to be a fact that the genus Anopheles conveys the parasites of malaria from man to man. A résumé of the literature on this subject would consume an entire evening. Important observations are now being made by original workers in the tropics and much information of practical value to the clinician is being worked out. The most striking fact which has apparently been definitely established and corroborated by recent experiments is that the cause of yellow fever is present in the blood of those attacked, and that certain mosquitoes can inoculate and that it is not transferable by the fomites. This is looked upon as a very important medical discovery, removing a large part of the mystery relative to the etiology of yellow fever.

Cancer.—Relative to the cause of cancer, Roswell Park of Buffalo and his collaborators at the State Hospital have been doing some excellent work. Park reports having been able to produce a true adenosarcoma in an animal by inoculation with fluid from the peritoneal cavity of a man suffering from colloid cancer of the omentum.

The Roentgen Rays in Practice.—Since the discovery, about five years ago, of the Roentgen rays, great advances have been made in the practical application of this mysterious form of energy. Somewhat reckless predictions have been made, born of enthusiasm at the startling revelations. However, time, which is of such great importance in testing new discoveries, has proven that the application of the rays is of great diagnostic and therapeutic value. At one time it was seriously feared that the prolonged exposure thought necessary for successful observation would interfere with its usefulness. Valuable improvements have been made in technic enabling the obtaining of very important results in brief periods and with our present knowledge, a diagnosis is possible in shorter time and with greater precision than could be obtained in any other way. With it, foci of tuberculous infection can be distinguished earlier than by the ear. It will show either unilateral or bilateral enlargement of the heart with any displacement of the organ. Emphysema, asthma, pleurisy, hydropneumothorax, pyopneumothorax, hydrothorax, and pneumonia, are all easily recognized and their limits demonstrated. Thoracic aneurisms are recognizable in their early stages. Cavities which have escaped detection by auscultation or percussion may be discovered. The presence of fluid in the pleural sac may be positively determined. Dr. Senn refers to the use of the X-ray during the late war as fully answering the expectations for diagnostic purposes. He says: "During the Spanish-American war the skiagraph enabled us to diagnose the existence or absence of fracture in a large number of doubtful cases in which we had to depend exclusively on this diagnostic resource. In fractures in close proximity to joints it has been of the greatest value in ascertaining whether or not the gunshot fracture extended into the joint. In the light of recent experience the X-ray has become an indispensable diagnostic resource to the military surgeon in active practice, and the suggestion the every chief surgeon of every Army Corps should be supplied with a portable apparatus and an expert to use it, must be considered a timely and urgent one." Its limit of usefulness has not yet been determined in medicine, but the X-rays have rendered valuable aid in the treatment of diseases of the skin, among them lupus vulgaris, lupus erythematosus, chronic eczema, vascular nævus, hypertrichosis, favus, and sycosis, and also in other pathological conditions of internal organs.

Neurology.—In considering the burning questions of the day one must include the bacterial toxins, serotherapy, organotherapy, autointoxication and the relations of the internal secretions to problems connected with the nervous system, that part of the human organism which in the main is accountable for man's lofty position which he holds among animals. The last decade has given birth to unprecedented activity in connection with the progress in neurology. The results obtained have led to a complete revolution in our ideas concerning the elements of the nervous organs and their mechanical relations and supplied us with a host of new methods of investigation in the prosecution of the study of the nervous system in health and disease. Entirely new avenues of research have been opened and problems heretofore thought beyond the reach of scientific inquiry now seem within human grasp. So numerous have been the methods of original research pursued that space and time forbid passing them in mental review.

I shall briefly mention a few of the main achievements in neurological science. Among the names which have shed new luster on the subject is one Ramon y Cajal; his connection with original work has been both brilliant and fruitful. If popular history can be relied upon, the story of the young Spaniard is remarkable from a medical standpoint. Developing in a country remarkable for its barrenness in original research, he applied for a position in microscopy, which was refused him. Being industrious and ambitious, his pride was wounded keenly. Disappointed, but not discouraged, he purchased a small library on histological subjects and microscopical appliances and began his original work, paying special attention to technic. He practically ostracized himself from society, worked like a slave and a decade later found himself famous. A brief inquiry into the contributions of this Cajal cannot fail to make clear why from different parts of the scientific world his productions attracted attention and gained for him a professorship at Madrid and notice and appre-

ciation by international audiences. This has been accomplished since 1888. Among the original contributions are: (1) the demonstration of the complete independence of at least the majority of nerve elements; (2) the appreciation of the widespread occurrence and significance of the lateral branches of the axis-cylinder processes; (3) the demonstration of the striking uniformity in general structure of the majority of nerve elements in all parts, despite minor morphological elements.

Since 1880, investigations of Golgi, His, Kölliker, Cajal and others have produced a complete change in our ideas, in relation to the elements of which the nervous system is constructed and also the mode in which these elements are architecturally put together. The Golgi method of staining tissue has become recognized in the whole scientific world, as the pictures of nerve-cells and their processes obtained by this method are incomparably superior to those obtained from any other method. Cajal, with his incomparable genius, made new applications of the Golgi method which created widespread attention and were looked upon in the light of a new discovery, and anatomists everywhere, in Germany, Von Kölliker and others, in Belgium, Van Gehuchten, in Sweden, Retzius, in England, Schäfer and Andriezzen, in America, Berkley and Strong and a host of others in this and other countries, set to work with this new method of osmo-bichromate mixture and silver nitrate and in a short time a new vista was opened up, and information supplied regarding the reciprocal relations of nerve units in the various parts of the cerebrospinal and sympathetic nervous system. The connection of the axis, cylinder processes of the cells of the neural horns with the axis cylinder, of the fibers of the motor roots of the spinal nerves, were first absolutely established by Weigert's method and the carmine methods of Gerlach. This in conjunction with improved technic in sectioning has contributed greatly toward the investigations in neurology.

The Neuron Concept.—In 1891 Waldeyer brought to the notice of the profession the doctrine of the individuality of the nerve elements. The neuron concept of the nervous system, in a nutshell is briefly, as follows: The nervous system, aside from its neuroglia, ependymal cells, blood-vessels and lymphatics, consists of an enormous number of individual elements of neurons. Each neuron in its entirety representing a single body or cell. The foundation for the neuron doctrine rests upon the following facts: (1) That the nervous system agrees with other parts of the body in being cellular; (2) the proof that in the embryo the nerve-cells exist as independent units, many of which are capable of wandering for considerable distance from the origin; (3) the fact that the nutrition of the nerve-cells is most easily explained from the standpoint of a doctrine which looks upon the nervous system as made up of units, which are not only anatomical but physiological.

Since this doctrine was advocated a large amount of work upon degeneration of nerve fiber and cells, has been done, especially by Marchi, which confirms the validity of the neuron doctrine; the latter being of value in enabling the histologist to follow the diseased nerve fiber to its termination. The conception of the neuron has helped to facilitate our understanding of some diseases, in showing that there is no cardinal distinction between gray and white matter, and it has helped to unravel the mystery which formerly surrounded those diseases that involved almost simultaneously the various systems of white fiber and the gray matter. Proportionately with the growth of the neuron concept the value of systemic diseases is lessened.

Psychiatry.—Do what we may, we cannot separate mental diseases from organic diseases of the brain and, indeed, diseases of many other organs of the body. The line of demarcation is so indistinct between the mental and physical conditions that in many instances one merges into the other. One of the foremost alienists of Europe said some time ago that psychiatry is on a level with the medical sciences of a hundred years ago, and that it was based wholly upon clinical studies and not upon pathological anatomy of diseased organs. A few years ago the American Medico-Psychological Association, whose membership is made up chiefly of men in charge of hospitals or asylums, where the insane are cared for, invited Dr. Weir Mitchell of Philadelphia to deliver the annual address. The eminent physician during the course of his remarks made some severe criticisms upon the lack of scientific work in hospitals for the insane, which aroused some indignation. That there is abundant material for scientific work, both clinical and pathological, in our large asylums, is undeniable and that there has been marked advance, both in the character of the clinical work done, also in honest endeavor along etiological lines, is conceded. That greater advancements have not been made is not to be entirely attributed to inertia on the part of those in charge, but is largely due, especially in relation to causation, to the well-known fact that the morbid pathology of the brain is more compiex than any other part of the human organism. Our asylum reports to-day, instead of being full of stereotyped data, are fast becoming storehouses of useful information, in relation to all that pertains to the care, cause and treatment of these unfortunates. To the practical psychiatrist the question of domiciliation does not overshadow every other desideration as it has done in the past. During the last decade the importance of the early diagnosis and treatment of mental disease, with accompanying pathological conditions, prompt separation from domestic surroundings and skilful treatment, mental, moral and physical, are questions which are of intense interest. The closer observation and recording of clinical facts and more systematic laboratory work by competent persons, either on the staff

or outside, have been established in many institutions. The pleasant, cheerful rooms and airing-court have taken the place of the darkened cell. We have the trained attendant, the beautiful grounds and modern architecture. The Kirkbride system took the place of the old quadrangular form of building, and now the cottage system in some form is fast superseding all others.

The work of Meynert on the cerebral cortex and the researches and experimental labors in Europe of Charcot, Flechsig, Wernicke and others, have done much to illumine hitherto considered impervious conditions. The work of the New York Pathological Institute under the leadership of the brilliant Van Gieson has received the recognition and commendation of many of the original investigators of this country as well as those of Europe; also the original contributions of Berkeley on the pathological lesion of the brain have stimulated the study of psychiatry throughout the hospitals for the insane of the United States. It is in keeping with this spirit and the honest endeavor on the part of those interested in the science of psychiatry, together with the increase of insanity ever and above the increase in population, which makes possible a psychopathic hospital in our State as established in connection with the older universities of Europe. At the present time there is no branch of medical science which offers so many interesting problems to solve. The past has been full of disappointments, but the future is full of hope.

We begin the twentieth century under most encouraging auspices. The century just closed will be known as the period of marvelous scientific achievement, pertaining to many of the departments of medicine and surgery and bringing to an end the age of dogmatic medicine. There are still many important subjects now receiving the most careful and profound consideration from scientific men in different parts of the globe; science in its march of progress knows no nationality, from Germany, Belgium, Sweden, Japan, Russia, Italy, France, Spain, England and our own country, come the reports of work embodying the true spirit of scientific research to an eminent degree. What of the future? That more brilliant achievements are soon to follow, few will doubt. Serotherapy is in its infancy and, although one of the crowning triumphs of the nineteenth century, in its use there are certainly great possibilities.

Psoas Abscess.—In these cases, even with very large abscess, R. W. MURRAY, LARKIN and others (*Liverpool Medico-Chirur. Jour.*, Sept., 1901) have obtained complete cure by incision in both lumbar and iliac regions, and sometimes also in the femoral region. The abscess cavity is thoroughly cleansed and the wounds all closed without drainage. The good results have been especially observed in children.

DEFORMITY ARISING FROM INJURY TO THE LOWER EPIPHYSIS OF THE TIBIA.[1]

BY B. E. M'KENZIE, B.A., M.D.,
OF TORONTO, ONTARIO, CANADA.

Case I.—In 1890 a boy eleven years of age had a gradually increasing deformity of the left foot. The following history was given: At two years of age he had disease of the tibia requiring operative intervention. The anterior surface of the tibia was marked by cicatrices. The foot was carried inward so that the body

weight was transmitted to the ground along a line passing to the outer side of the foot. This deformity was observed to increase constantly and the disability was more marked as time passed. The explanation which suggested itself as the causative factor in this increasing deformity was in a relative shortening of the tibia in its relation to the fibula. This relative shortening no doubt resulted from the inflammatory affection of the bone in infancy, which had caused a synostosis at the junction of the lower tibial epiphysis with the shaft and consequent relative loss of growth in length of that bone while the fibula made its normal increase in length.

Operation.—A section about one inch in length was removed from the fibula subperios-

[1] Read at the meeting of the American Orthopedic Association, June 11, 12 and 13, at Niagara Falls.

teally and the tibia was cut through at the same level as near to the lower end as was thought safe, and the foot moved outward in its relation to the leg, to its normal position. On account of the boy's age it was thought that the deformity would recur, hence the epiphyseal cartilage was removed from the lower end of the fibula. Healing was satisfactory and the result gratifying, the boy having a well-placed foot with about two inches of shortening. Some years subsequently it was found that the foot retained its corrected position and that the measures adopted had been entirely successful.

Case II.—T. W., sixteen years of age, while playing in a barn three years previously, had jumped from a height, fracturing the leg near the ankle. The adjustment of the fracture and recovery were uneventful, the leg and foot being found in good position with normal movement. After the lapse of nearly a year it was noticed that the foot was disposed to turn over upon its outer border and this tendency increased constantly as time passed, till at the end of three years the foot could not be kept directly under the transmitted body weight and walking was becoming increasingly dangerous.

It seemed manifest that either the primary injury consisted of a separation of the tibial epiphysis or that the process of healing in a fracture near the epiphyseal junction had caused premature osseous union between the epiphysis and the diaphysis.

Operative measures similar to those employed in Case I. were carried out, with the exception that the age of the boy precluded the necessity of removing the epiphyseal cartilage from the fibula. The result is highly satisfactory.

Case III.—Norman T., eight years, when playing in a harvest-field four years previously, had run in front of the knives of a reaping-machine, which cut the leg just at the ankle-joint, so that the only structures left uninjured were the tendo Achillis and the blood-vessels, nerves, and tendons behind the inner malleolus. The surgeon in attendance found that numerous pieces of bone had been shaved off. These were removed and the suturing of nerves and tendons carefully done. Healing was satisfactory and the result excellent, the foot being in good position and having good movement.

After a considerable lapse of time an inward displacement of the foot was observed similar to that described in the former cases. A similar explanation, I am confident, will alone account for the deformity. So far as I know there has been no operation performed as yet for the relief of the deformity in this case.

Separation of the epiphyses is not of frequent occurrence; and of the various epiphyses separation of that of the tibia is one of the less frequent to happen. Mr. Hutchinson, as quoted by Treves, in 1895 had seen 17 cases of separation of the lower radial epiphysis; 14 or 15 of the lower humeral; 13 of the upper humeral and 10 of the lower femoral. In a collection which he made of over 350 reported cases there were of the lower femoral 75; upper humeral 66; lower radial 54; lower humeral 52; internal epicondyle 38; lower tibial 27; upper femoral 26; great trochanter 11; upper tibial 10; tibial tubercle 6; lower ulnar 6; upper fibular 4; clavicular 3; upper radial, upper ulnar, and lower fibular 2 each; small trochanter 1.

I can find no reference in literature to the production of the deformity which has been described in this paper. Synostosis at a time when the growth is not complete, and consequent relative shortening of a limb are frequently noted; but I have not found any reference to deformity consequent upon early synostosis occurring in one bone at a part where there are two bones forming the proximal portion of a joint. I have not seen a similar deformity of the hand, but have seen a plaster model of a hand and arm whose deformity must have been caused by a similar epiphyseal injury.

12 East Bloor Street.

DANGERS TO PUBLIC HEALTH AND MORALS, ESPECIALLY TO YOUNG PERSONS, FROM QUACKERY, AS PROMULGATED BY PUBLIC ADVERTISEMENTS.

BY E. STUVER, M.S., M.D., PH.D.,
OF FORT COLLINS, COLORADO.

Quackery is defined by the Standard Dictionary as "boastful pretension, or ignorant or fraudulent practice; charlatanry."

True scientists and really great discoverers are modest and unassuming. From Hippocrates down to our own quiet workers nearly all great advances in arriving at a clearer and more thorough knowledge of the causative factors of disease and the best means of effecting cures and alleviating human suffering as well as the most effective methods of staying the ravages of plague, pestilence, and epidemic diseases have been accomplished by men who shunned publicity and notoriety, who spent long years of patient and arduous toil in perfecting their results.

Were these men sustained, encouraged and helped in their unselfish efforts to remove the ills, soothe the sufferings, and raise mankind to a higher and happier plane? The echoes of history reverberating down the corridors of Time answer with a most emphatic No! Instead of being helped, encouraged and rewarded, they were nearly always abused, vilified, and in some cases almost mobbed on account of the work they were doing. As illustrations of this, wtiness the struggles and persecutions through which the early anatomists and physiologists had to pass in their endeavors to gain a clearer and more comprehensive knowledge of the structure and functions of the human body for the purpose of curing or alleviating its diseases. Think of the ridicule and abuse heaped upon Jenner, the immortal discoverer of vaccination, whose great discovery saved many lives, relieved much suffering, and,

by lifting the dark pall of terror and dread, did much to raise mankind from the abyss of gloom and despair, and, while endowing all races and peoples with safety against this dread destroyer, inspired them with hope and comfort.

We need not go back to the remote past for examples of this perversity and misrepresentation; we have our own antivivisection societies, and other obstructionists who are "moving heaven and earth" and resorting to every means, fair and foul, in their efforts to impede the progress of science and obstruct the work of scientific investigators. In order to compare the conditions under which we at present live, and those which existed under the régime of empiricism and restrictions for which the obstructionists are so loudly clamoring, let us draw aside the curtain of history and gaze on the results of thousands of years of empirical experience.

Do this, and we behold plague and pestilence sweeping over the land, leaving desolation and death in their track. Here we see cities converted into vast charnel houses, the streets covered with dead bodies, and not enough well to care for the sick and dying; there we behold uncoffined corpses rolled into great trenches, or left as food for ravening animals or to pollute the atmosphere.

We who enjoy the immunity afforded by vaccination can scarcely believe that such ravages were caused by smallpox in London as are so graphically described by the historian Macaulay, who informs us that it was a rare thing at one time to find a person in that great city not disfigured or marked by the dread disease. When we emerge from the mephitic atmosphere, laden with ignorance, disease and death, of the London of two centuries ago, with its death-rate of 80 to the 1,000, into the clear light of sanitary and medical progress of the present time with its death-rate of less than 20 to the 1,000, in civilized countries, we feel like one who has passed through some terrible danger, who has been surrounded by invisible and relentless enemies, which, happily, have been routed or are being put to flight by the knowedge resulting from experimental investigations.

But why, you ask, are such things possible? How can human perversity go to the length of standing in the way of those things which are most essential to human development and the welfare of the race? How can reason tolerate such a suicidal course?

To the unselfish lover of truth and humanity the above may seem an insoluble question, but the careful student of men and events, who clearly sees the intimate commingling of good and evil in the world, appreciates the fact that while good is generally quiet and retiring, depending on the truth and justice of its claims to secure its ultimate recognition, error and pretension are bold and arrogant, and use every possible means to compel the world's recognition, and supplant the truth.

Quackery, owing to the boldness and effrontery of its claims as well as the insidiousness and wide diversity of the means used for its promulgation, has become firmly established and is making most strenuous efforts to maintain its position. While many things contribute to the continuance of its influence and power, no other one agency is so powerful; indeed, I believe I am justified in saying that all other agencies combined are less potent in maintaining its baleful prestige than public advertising and public notices in newspapers and magazines.

In proof of this statement I desire to call attention to the following facts: The statements, arguments and everything calculated to promote the propaganda of antivaccinationists, antivivisectionists, Christian scientists, osteopaths, vendors of quack medicines and sure cures of all kinds, as well as fakirs and swindlers of every class, nationality and description, who are using every means in their power to hinder and impede scientific medicine and sanitary science, are given laudatory notices and unlimited space in the newspapers, while the scientific physician is not even accorded space in the papers which published the pseudo-scientific vaporings, misrepresentations, and attacks, to answer them. Why is this? Because these fakirs pay well for their advertising space; indeed, they contribute a considerable part of the revenue of large newspapers, and as reputable physicians do not do this, the advertisers receive the whole support of the newspapers, no matter how false their statements or how nefarious or harmful their business may be. Then, too, when so-called commercial or business interests are at stake, behold how these self-constituted guardians of public health, conservators of public morals, and promoters of justice and truth do vilify those who are trying to do their duty and protect the public! How they cover up or pervert fact, and use every means in their power to hinder scientific investigations was well illustrated in the recent outbreak of bubonic plague in San Francisco. Such a policy as this, like the ostrich hiding his head in the sand, is extremely shortsighted and harmful, suicidal, indeed, we might say, because when the truth becomes known, the right prevails, and the guilty city or town must suffer the penalty of its selfishness and duplicity.

By the prominence given in the newspapers to the statements of those who oppose sanitary measures, such, for instance, as the opposition to vaccination, the isolation or quarantining of contagious diseases, and similar measures, many people are led to believe that such measures are unnecessary, and a harsh assumption of arbitrary power; also that they are only advocated by a small clique of health officers, so that, instead of hearty co-operation with the health authorities in their efforts to stamp out disease, cases are concealed and new foci of infection are established. This results in the spread of diseases and in much loss, suffering and death. In the same way the wide publicity given by means of public notices, to the opposition to scientific experiments

on living animals, which have for their object the discovery of new agents and measures for the prevention and treatment of such diseases as diphtheria, typhoid fever, yellow fever, bubonic plague, etc., have created such a popular prejudice against this beneficial work that it is with the greatest difficulty that the passage of restrictive laws are prevented. Every one who has ever studied the subject in an unprejudiced manner knows that many of the most useful and beneficent discoveries that have ever blessed humanity have been the direct result of these experimental investigations on living animals, and they cannot fail to see that the great publicity given to the loud vaporings and maudlin sentimentality of the antivivisectionists is a serious menace to the public health, besides interfering with scientific progress.

The large amount of space given by the newspapers to osteopaths, Christian scientists, and all kinds of blatant medical fakirs and vampires, is detrimental to sanitary science and public health, because it is largely through advertising that the exaggerated or false claims of these pretenders are forced upon the people. Many a man and woman has been duped, and themselves, as well as their children, made to suffer, through ignorance or cruelty because they believed the advertisements in their newspapers and were thus induced to entrust the health of themselves and their families to the care of these so-called "healers."

Had these same people come to them without the endorsement of a paper or magazine in whose honesty of purpose and integrity they had confidence, they would have laughed at them for their pains.

Truth, honesty, and virtue, and obedience to the laws of man, Nature and God, are the fundamental principles and crowning characteristics of a noble manhood and womanhood. I shall define crime, vice and sin as follows: Crime is a violation of the laws of legitimately organized society; vice is a violation of the laws of Nature, and sin is a violation of the laws of God. Any cause, influence, or instrumentality which weakens man's love and respect for truth, honesty and virtue, or lessens his obedience to human, natural and Divine laws, to that extent impairs the grandeur and nobility of his character, and lessens his influence toward society.

Taking these fundamental principles as a criterion by which to judge, let us see what influence quack advertisements exert on public morals. A systematic exaggeration and often misrepresentation permeates public advertising in every business, profession and calling of life. But while this is true of all vocations, nowhere is it so fraught with danger to the health and morals of the people as in connection with the exploitation of remedies and agencies designed for the cure or alleviation of the many physical and mental ailments to which the human race is subject. "A little learning is a dangerous thing." "Drink deep, or taste not the Pierian spring" is an injunction which would be of immense benefit to the great majority of people, if they would but apply it to the management of their physical ills, about which they are profoundly ignorant. Even eminent ministers, judges, and politicians, who may be very learned in their own particular callings, in most cases exhibit gross ignorance and crass credulity when they attempt to pass judgment on medical subjects. This is very unfortunate for the people, because, were it not for the fostering help and assistance of these eminent patrons, many of the humbugs and harpies who are now preying on society would pass into "innocuous desuetude," and die of inanition.

If a half truth is the worst kind of error, what must we think of the patent medicine advertisements, which with all the arts of the modern advertiser, try to delude the public into believing (and often do it, too) that their grain of truth mixed with bushels of the chaff of error is all pure seed and will germinate and yield a most bountiful and beneficent harvest? What a shock must the poor deluded victim experience when, instead of the rich and bountiful feast he was promised, he receives but a single bite. How must his regard for truth and honesty be affected by such wonderful results!

How beautiful his simplicity, faith and confidence in the truth and honesty of mankind *before* investing in the much-lauded *sure cure* for consumption, cancer, epilepsy, or some other incurable disease! How shattered all his aspirations *after* he has seen these vaunted pretensions, like apples of Sodom, fall to ashes in his hands! Surely, he must conclude that the standard of honesty and truth which permits the pious minister, the learned judge, or the brilliant and versatile politician to praise and recommend the nostrums by which he was deceived and defrauded, ought to be good enough for him, and he henceforth continues life on a lower moral plane. But, while exaggerated and lying advertisements are slowly but surely sapping the foundations of truth and honesty, a thousand times more harm is being done by means of an insidious and deadly virus with which they are poisoning the very foundations of virtue, and swelling the deadly stream of vice, crime and sin! Take up almost any of our great dailies, and what will you find? In one column you may read the flowery, rhetorical outburst of an eloquent divine as he descants on the purity of the press, and nearby the fervid appeal of the conscienceless fakir who no less eloquently recounts the virtues of his specific for "lost manhood." On one page may be found a dissertation on the home and its sanctity, the sacredness of human life, the proper education of children, and the inculcation of correct moral and ethical principles, while on the next you will see a glowing eulogy on the effectiveness of "Mr.——'s" fakir "tansy pills, as a "sure cure for ladies in distress." Carried away by the tide of great achievements, you will meet in another column the blazing and much pictured "ad" of "Dr. Cure-em-all," who

positively guarantees to cure syphilis and all blood diseases, and remove to the last dregs the results of youthful indiscretions. Here we learn how the worn-out old debauché may be restored to his pristine vigor, and be sent on his way rejoicing, perchance to bring into the world a stainless progeny in his old age; how the ills and satiety of the ancient leader of the *fast set* may be removed, and she be re-habilitated in the charms and beauty of youth and the roseate dreams of twenty years ago return in all their glory.

Is it any wonder, then, that, with such claims and promises as these daily brought before his eyes, the youth is encouraged to plunge into excesses that he would have avoided had he been plainly and honestly told that every violated law of Nature would surely be punished with unerring certainty, and that instead of the results of his profligacy and vice being easily, pleasantly and safely eradicated, they would be transmitted to enervate and curse his children for generations in the future? Would he be so reckless and profligate in "sowing his wild oats" if he felt assured that his condition would, in a large percentage of cases, consign a loving, trusting wife to a life of chronic invalidism or an untimely grave? On the other hand, would the young girl who is strongly tempted by the impulses and environments of youth be so likely to yield to temptation and abandon the path of virtue, had not the siren and delusive song of the advertisement, ever before her eyes, impressed on her mind that "——'s tansy pills" were an unfailing safeguard and a sure anchor of hope in the hour of dire necessity? If she felt that motherhood would probably be the penalty of yielding to passion, there would be a strong restraining influence to keep her virtuous. "*Decensus averno facile est.*"

"Vice is a monster of so frightful mien,
As to be hated needs but be seen,
But seen too oft, familiar with her face,
We first endure, then pity, then embrace."

These words of the poet very truthfully and vividly portray the influence that may be exerted by the vile, erotic and depraving advertisements which are ever before the eyes of the young, and the condition of those who, having abandoned the paths of truth and virtue, are rapidly whirled along towards the vortex of physical and moral destruction.

First high, noble and Christian sentiments are disregarded and become obtunded; then yielding to the influences of the insidious and fatal virus, minor indiscretions are committed; later vice, istead of being a monster of frightful mien, seen through the mists of a perverted mind and unrestrained passions, becomes a goddess arrayed in splendor and glory, and is gladly clasped to the bosom, and finally, the dim specter murder, in the form of the abortionist, becomes a welcome refuge to the unhappy victim who conceals the foul, cowardly and unnatural crime, and even attempts to excuse its commission.

While some may think this indictment is too severe, I am convinced that no one conversant with the facts will deny the truthfulness of the picture. That criminal abortion is disgracefully prevalent, every physician only too well knows; that it is a most serious crime, being no more or no less than plain murder, as viewed from a biological standpoint at least, all right thinking persons will admit; that it is leaving a broad trail of physical and moral death and devastation, and is a potent cause of degeneration in our people, is very well known; still with all these facts plainly before us the newspapers are permitted continually to publish their vile suggestions and incentives to this horrible crime.

In conclusion, I desire to present the following summary:

1. The great life-saving discoveries have been made by quiet, unobtrusive men.

2. Quacks and charlatans have never made any great discoveries in sanitary science, but, on the other hand, have always opposed scientific progress and investigation.

3. Quackery flourishes best in an atmosphere of ignorance, credulity, and pseudo-science, and is promulgated by boastful, arrogant pretensions, and public advertising.

4. Antivaccinationists, antivivisectionists, Christian scientists, *et id omne genus,* by opposing preventive sanitary measures and scientific investigations, facilitate the spread of contagious and infectious diseases, oppose the stamping out of diseases already established and impede investigations as to the causation, prophylaxis and cure of disease.

5. The newspapers, which derive a large part of their revenue from advertising, nearly always espouse the cause of the so-called commercial interests, regardless of the fact whether they are supported by truth and justice, or are opposed to the best interests of the public. This is well illustrated by the recent occurrence of bubonic plague in San Francisco.

6. The boastful pretensions and misrepresentations of quack advertisements (patent medicines) lower the public regard for truth and fair dealing and encourage falsehood and duplicity.

7. The bold and shameless introduction of advertisements, calling attention to and suggesting vile, immoral and even criminal acts, debases and demoralizes the young, and leads to disease, crime and degeneration.

MEDICAL PROGRESS.

Scarlatinal Nephritis.—The anatomical changes in the kidneys during the first week of scarlatinal nephritis consist in a circumscribed or more diffuse cellular infiltration. In the second week there is besides this degeneration of the epithelial cells of the straight and convoluted tubules with occasional embolic foci of necrosis. It is only in the third week, according to A. BABINSKY (*Klin. therap. Woch.,* Oct. 27, 1901), that marked changes are noted in the Malpighian capsules and glomeruli. The im-

portant clinical symptoms are: (1) Fever; this may still be due to the scarlatina or one of its complications. Sometimes it is entirely absent and even fatal uremia may occur without any rise. In most cases, however, there is a gradual or a more sudden rise up to 39 or 39.5° C. The most dangerous forms are those with highest fever. Finally, there is a group of cases in which every exacerbation of the nephritis is marked by a new rise. (2) Pulse; generally there is no definite relationship between this and the fever. The wiry condition of the pulse in uremia is peculiar. (3) Amount of urine; in typical cases this is diminished, yet there may be normal quantities of normal specific gravity voided and anuria with a fatal issue may set in suddenly; or there may be polyuria up to 2,000 c.c. in children from six to eight years. (4) Foreign elements in the urine; cases with large amounts of albumen are the most dangerous; when the urine contains hemoglobin and has a dirty, coffee-brown color, the outlook is serious, yet cases with over 4 pro mill. albumen have been cured. (5) Hydrops; in its mildest form this manifests itself in edema of the eyelids. More marked edemas of the skin and effusions into the serous membranes considerably influence the prognosis and are apt to be complicated with bronchitis and pneumonia. Only in cases which come to treatment during the first five days can prophylactic measures be taken. (6) Uremia; with this there may be arhythmia and a wiry pulse, delirium, crying spells, aphasia and singultus. The amount of urine is subject to considerable variation; there may be anuria or polyuria. Very often the mildest cases are followed by the severest attacks of uremia, in most cases, however, the outlook is fair. Of 88 cases of nephritis under observation the author lost 11, and of these 3 were complicated by other disorders. In 18, however, a chronic albuminuria remained, which in 5 developed later into chronic nephritis. The most careful prophylaxis and most painstaking therapy are unable to prevent the appearance of nephritis, but will do much to ward off the hydrops, uremia and subsequent chronic nephritis. The patients must remain in bed four weeks; during the first two only milk is to be given and during the last two a solely vegetable diet. It is best not to give any drugs at all and only to administer tannic acid in prolonged albuminuria or hematuria. Diuretics are only to be employed in the form of alkaline waters. The uremia is combated by means of venesection, sweating, chloral and chloroform. For chronic albuminuria, change of climate is indicated.

Catheter Fever.—The importance of absolute asepsis in the introduction of instruments into the bladder to ward off catheter fever is ably discussed by C. POSNER (*Deutsche Klinik.*, Vol. 10, p. 34). The hands demand an attention equal to that for a major operation and the instruments must be absolute germ-free—a condition which is easily obtained with those of metal, but is more difficult with the elastic catheters where disinfection in formalin-vapor or in streaming steam is suitable. The cleansing of the meatus is safely accomplished by means of soap and sublimate and for the urethra a weak solution of boric acid is serviceable, though less thorough, so that it is well to follow the introduction of instruments by irrigation with a 1:1000 silver-nitrate solution. For the development of fever, which in the majority of cases depends upon an infection, stagnation of the bladder-contents, which allows the germs to gain a good foothold, and often a loss of continuity, which permits the bacteria or their toxins to enter the system, are necessary. The mildest forms of infection do not show themselves by fever, but by a mere turbidity of the urine, due to pus cells, which goes to show that the deeper parts of the entire urinary system possess means of protection against the overflooding of the system with germs. This protection is least in the posterior urethra, owing to its connection with the prostate, which is rich in lymphatics. The loss of continuity is generally a direct result of mechanical injury; often, however, the sudden relief on drawing off the urine causes rupture of the vessels and thus a ready means of entrance for bacteria. But few cases depend upon absorption of toxins alone and here also an injured mucous membrane is necessary, since the healthy mucosa of bladder and urethra do not absorb. The symptoms of catheter fever resemble the invasion of any other fever; where absorption is prolonged a sort of intoxication manifested by dry tongue, small and irregular pulse, general malaise and, in the severest cases, subnormal temperature occur. The two chief internal antiseptics which have yielded good service in the treatment of catheter fever are quinine and urotropine. The latter is especially valuable in central vesical paralysis. The question of local treatment is much more difficult to answer and must be decided for each individual case. Where there is a fresh wound and the urine must constantly pass over raw surfaces, a permanent catheter often is excellent. In all cases free action of the skin, kidneys and bowels is to be secured.

Tuberculous Pericarditis.—In a case of this kind reported by DEMPSEY (*Dublin Jour. of Med. Sci.*, Oct., 1901), the fifth left intercostal space was incised under beta-eucaine, the internal mammary vessels tied, the pleura pushed aside, the pericardium incised, and about 1,500 c.c. (50 oz.) of clear fluid evacuated. This was subsequently found by culture and by microscopical examination to contain tubercle. The patient felt much

relieved after the operation, but suddenly died convexity of the aortic arch was thought to be pletely caseated state and situated close to the the same evening. A lymphatic gland in a comthe origin of the pericardial affection. The question arises as to the rôle played by the rapid evacuation of fluid in the sudden death.

Epilepsy.—"A really good prognosis can seldom be given," writes SIR WILLIAM GOWERS, "unless all the attacks are averted by the bromides in moderate doses, such as fifty or sixty grains a day." His treatment is by potassium bromide, no advantage of other bromides over this having been noted. In 1899, at the National Hospital for Paralyzed and Epileptic, there were used 3,664 pounds of potassium bromide, 313 pounds of sodium bromide, and 123 pounds of all other bromides. The bromide acne eruption may be entirely prevented by the addition of arsenic. Borax, zinc and a few other drugs are useful, and belladonna and digitalis may increase the effect of the bromide. Nitroglycerin does not influence the attacks, and opium may be distinctly dangerous.—"Epilepsy and Other Chronic Convulsive Diseases."

Physostigmine in the Treatment of Intestinal Atony.—The action of physostigmin on the intestinal tract has recently been tested by Traversa, an experimenter upon animals. Popular as this drug is in veterinary practice, the medical profession remains indifferent to its attractions. C. VON NOORDEN (*Berl. klin. Woch.*, Oct. 21, 1901) describes the clinical uses of Calabar bean and its alkaloid. In cases of extreme and obstinate tympany complete symptomatic relief followed the administration of $^1/_{100}$-grain doses of physostigmine. The drug was a symptomatic success even in cases of typhoid fever, a disease in which tympany may be exceedingly troublesome. Physostigmine salicylate is so powerful a drug that it is best to begin its use with very small doses. In case of accidental poisoning it is well to remember that the toxic effects of physostigmine are opposed by atropine.

Phantom Tumors of the Abdomen.—Irregular contractions of abdominal muscles or of parts of such muscles are perplexing and may easily be mistaken for abdominal tumors. MAX EINHORN (*Berl. klin. Woch.*, Oct. 28, 1901) points out that phantom tumors may be due also to prolapse of the left lobe of the liver, to exposure of the abdominal aorta, to local hypertrophies of muscular tissue, and to adhesions about the lesser curvature of the stomach. If the left lobe of the liver be prolapsed the pseudotumor is found in the median line close to the ensiform process; just above the resistant mass, in the region normally yielding hepatic dulness, an unusually tympanitic percussion note is obtained. Where the aorta forms the suspected mass, the latter is found deep in the peritoneal cavity, close to the spine; it is cylindrical in shape and pulsates vigorously. Such a tumor is frequently mistaken for an aneurism. A mass of muscular origin is superficial and lies to the left or right of the linea alba. The surface is not spherical, as in the case of prolapsed liver, but rather flat, although laterally a slightly curved surface may be palpated. In general phantom tumors present smooth rather than nodular surfaces. Palpation at various times yields different results; at times nothing can be felt. A marked grade of enteroptosis is a common accompaniment. A history of many years is usually given and helps to exclude malignant growth. Phantom tumors may occur at any age, and are often associated with a poorly-nourished condition of very long standing. Rapid loss of weight does not of necessity indicate a malignant growth, as is shown by the clinical histories which form a part of Dr. Einhorn's article. The rational treatment of phantom tumor, according to this author, consists chiefly of moral suasion and good nourishment.

Diagnosis of Inflammatory Exudates in the Iliac Fossa.—The extreme importance of leucocyte-counts in cases of purulent exudation is emphasized by CURSCHMANN (*Fortschritte d. Med.*, Oct. 22, 1901). Physical diagnosis, even with the aid of aspiration, may yield only negative results in these cases. But if other diseases causing marked hyperleucocytosis, such as pneumonia, can be excluded, then a leucocyte-count of over 20,000 indicates pus with practical certainty. In cases of non-purulent inflammation there may be a hyperleucytosis at the very beginning, but this rapidly disappears and as a rule is not even temporarily present. If a leucocyte-count of over 25,000 be made it probably means pus even in a very early case. Leucocytosis, according to Curschmann, is of greater diagnostic value than the temperature curve.

Surgery of Pulmonary Abscess, Gangrene and Bronchiectasis following Pneumonia.—The prognosis of abscess and gangrene following pneumonia, medically treated, is not very favorable. Many cases of both varieties can be successfully treated by pneumonotomy. D. N. EISENDRATH (*Phila. Med. Jour.*, Nov. 9, 1901) has gathered statistics showing a marked increase in the percentage of recoveries, especially in cases reportd within the last five years, over that of the preceding decade. One of the greatest difficulties is exact localization of the focus. The prognosis for chronic cases is not so favorable. The patients are usually operated on when in an emaciated condition, and the walls of the cavity are often rigid, so that they do not contract well after being drained; the free communication of a bronchus with such cavities is also a barrier. Better results seem to be obtained in these cases when the affected portion of lung is excised.

Typhoid Bacillus in Urine.—During the past twenty years various observers have noted the excretion of the typhoid bacillus in the urine and their collected figures show this condition to be present in about thirty per cent. of all cases examined. These statistics are given by M.

SCHUER (*Deutsch. med. Woch.*, Oct. 31, 1901) and to them he adds his own observations in a series of twenty-two cases, with a percentage of 22.7. His method was to take 5 c.c. of morning urine collected in a sterile vessel, mixed with a 15-per-cent. gelatin solution and spread out over the usual culture plate. After five days' incubation at 22° C. the resultant cultures were subjected to the usual confirmatory tests. He has found that severe cases of typhoid, with an albuminuria present, are more apt to show the bacilli in the urine, although milder cases do not form an exception, and also that, although found before defervescence, they are most frequent and in larger numbers during convalescence, and may be demonstrated for many weeks. It is therefore advisable to disinfect thoroughly all urine of typhoid patients and also the bath-water in which urine is often voided.

Bacteriology of Typhoid Pneumonia.—The presence of typhoid bacilli in the sputum of typhoid patients, who during the course of this disease have developed a pneumonic condition, has been demonstrated during the past few years by a number of observers, and it is now generally conceded that in a fair percentage of cases in which pneumonia complicates typhoid fever the typhoid bacillus is the specific cause of the lung lesion. The possibility that the typhoid bacillus may primarily gain entrance into the lungs and produce a pneumonic condition previous to the general infection of the body has also been admitted, but very few instances of such a sequence have been actually demonstrated. In this connection A. DIEUDONNE (*C'tlblt. f. Bak.*, Oct. 15, 1901) reports an interesting case. The patient was suddenly taken ill with a chill followed by fever. Percussion was negative, but auscultation gave roughened breathing and râles over the lower lobe of the right lung. The expectoration was "rusty." The following day physical signs showed consolidation of the lower right lobe. At this time the spleen was not enlarged. On the eleventh day characteristic rose spots appeared and the Widal reaction was positive. Typhoid bacilli were at this time recovered from the sputum. Later they were obtained in pure culture from the urine. Coincident with the occurrence of the general infection the spleen became enlarged. Recovery followed, the specific bacilli remaining in the sputum for seven weeks after convalescence. From prophylactic standpoints the recognition of this class of cases is of great importance, as hitherto the presence of typhoid bacilli in the sputum of such has not been fully appreciated and they have formed fruitful sources for the dissemination of these organisms.

The Clinical Significance of Atrophy of the Uterus During Lactation.—Atrophy of the uterus during lactation is largely physiological and is known to occur in most but not all nursing women. The degeneration of uterine muscle fibers proceeds more rapidly than the opposing process of regeneration and a normal shrinking of the organ results. L. FRAENKEL (*Arch. f. Gyn.*, B. 62, H. 7) studied 95 cases clinically and found that the atrophic tendency, beginning usually during the third month of lactation, ceases spontaneously when nursing is discontinued or even before. Amenorrhea occurring in a woman who has nursed her child longer than nine months is due more frequently to a new pregnancy than to atrophy of the uterus secondary to lactation. Gynecological symptoms other than amenorrhea occurring during lactation are in most instances associated with a uterus of at least normal size and hence should not be too readily attributed to uterine atrophy. As a rule it is wise not to order lactation discontinued when such symptoms occur between the third and seventh month of lactation, unless the symptoms are very marked indeed. Fraenkel does not consider the existence of a moderate grade of anemia an indication for putting an end to nursing. A good plan is to reexamine the uterus at intervals of four weeks in order to ascertain whether or not a progressive atrophy is taking place. Progressive atrophy being definitely established, lactation should cease at once; on the other hand, if the uterus be found to increase in size lactation may be permitted until the twelfth month. The writer concludes that pathological atrophy of the uterus is for the most part a result of excessive prolongation of lactation, although such atrophy is only found in a very small fraction of cases where nursing is overdone. It is worth while to guard against superlactation, inasmuch as the uterine atrophy resulting therefrom is not easy to overcome; the prognosis remains doubtful even when rational treatment is promptly begun.

Meningitis Due to Tubercle Toxins.—The action of bacterial toxins upon the tissues of the nervous system is of interest in relation to the pathogenesis of the nervous manifestations present in infectious conditions. ARMAND-DELILLE (*Comptes Soc. Biol.*, Oct. 25, 1901) has investigated the action of tubercle toxins upon nervous tissues. He employed the ethereal extract of tubercle bacilli. He inoculated dogs with this substance by lumbar puncture; some in the subarachnoid and others in the epidural space. These animals developed a paralysis beginning on the fifteenth day following inoculation. Upon autopsy those inoculated in the subarachnoid space showed a leptomeningitis, while a pachymeningitis was present in those which had been inoculated epidurally. These lesions extended from the dorsal to the sacral region. This work shows that the inoculation of tubercle toxins into the rachidian meninges is followed by plastic inflammation similar in symptomatology and pathology to that which supervenes in the course of certain cases of tuberculosis in the human subject.

Protargol in the Treatment of Gonorrhea.—As a test of the efficiency of local treatment of gonorrhea by means of protargol, KESJAKOFF (*Wiener klin. Rundschau*, Nov. 3, 1901) has tabulated a series of cases showing the time required for the disappearance of the gonococcus from the urethral discharge. In 12 per cent. of

his cases this occurred after a week; in 18 per cent. of the cases observed two weeks were required; in 30 per cent., three weeks; 20 per cent., four weeks; 14 per cent., five weeks; 6 per cent., six weeks. Kesjakoff's observations agree substantially with those of Meyer and Benario, Straus, Finger, and Ruggles.

Action of Emetine.—The action of emetine on the blood-vessels is of interest in relation to the effect of this drug upon congestive and inflammatory conditions. M. E. Maurel (*Comptes Soc. Biol.,* Oct. 25, 1901) has observed the results produced on the blood-vessels of the intradigital tissues of frogs by the inoculation of the hydrochlorate of emetine. His work shows that this substance is a powerful vasoconstrictor, increasing the normal circulation and reëstablishing a circulation which has become arrested. In the congestive zone surrounding a wound this action overcomes vasodilation and markedly reduces the degree of inflammation. This de-congestive action, so to speak, explains the excellent results which have been obtained clinically by the employment of ipecac in affections accompanied by congestion, notably in the digestive and respiratory systems.

Anterolateral Colpoceliotomy.—The advantages of the operation of anterolateral colpoceliotomy are stated by A. Duhrssen (*Berl. klin. Woch.,* Nov. 4, 1901), who proposed this operation some months ago. Dührssen shows that the division of the broad ligament does not interfere with the nourishment of the uterus, which is amply supplied with blood by the uterine and ovarian arteries of the opposite side. The indications for the division of the broad ligament are stated as follows: (1) The first stage of the operation, *i. e.,* the division of the ligamentum cardinale only, is indicated when a large ovarian abscess or a pyosalpinx is present which offers the prospect of cure through wide opening and drainage; (2) the complete division of the broad ligament is desirable when fixation of the uterus has resulted from chronic parametritis or from extensive adhesions between the adnexa and the pelvic wall. The division of the broad ligament is further recommended for purposes of drainage in cases of infectious purulent peritonitis; to facilitate effective tamponing in cases of hemorrhage from the surface of the uterus, from torn adhesions or from the ligamentum infundibulopelvicum; for the purpose of repair by suture and drainage in cases of rupture of the uterus. Should the uterus and the adnexa prove to be hopelessly diseased, the operator can proceed to total extirpation without loss of time due to the preliminary division of one broad ligament. While partial ligation of the broad ligament has long been practised in the treatment of parametritis, intraperitoneal abscess and diseased adnexa, Dührssen claims to be the first to propose complete division of the ligament in combination with anterolateral colpoceliotomy.

Origin of Polynuclearneutrophilic Leucocytes.—The origin of the polynuclearneutrophilic leucocytes has been the subject of much discussion. Ouskow regards them as derivatives of the lymphocytes, while Ehrlich maintains that they come from the myelocytes and are produced in the red bone-marrow. Dominici (*Comptes Soc. Biol.,* Oct. 25, 1901) holds that in the vast majority of cases they are descendants of the myelocytes, but claims that these are of lymphocyte origin. Thus the polynuclearneutrophilic is the last link in a chain the first link of which is the lymphocyte and the intermediate links myelocytes. The place of origin of the polynuclearneutrophilics is not exclusively the red bone-marrow, but they may also be formed in the lymph-glands and spleen. It would at first appear that this conception is merely a combination of the theories of Ouskow and Ehrlich; such is not, however, the case, as the first observer denies entirely the myelocyte origin while the latter affirms that they never normally come from lymphocytes. It is virtually an amplification of Ouskow's theory. Dominici admits that under certain conditions of abnormal myelogenous tissue a portion of the polynuclearneutrophilics may be formed directly from the lymphocytes without intermediate myelocyte formation.

Hot-Air Douche.—By means of the hot-air douche a marked local hyperemia can be produced on any part of the surface of the body and the cutaneous secretion can be increased; cell-activity is enhanced under the influence of hot-air currents and the output of products of metabolism increased. Assuming that neuralgias are ordinarily due to disturbances of circulation involving imperfect removal of the metabolic products of nerve-cell activity, B. Belzer (*Berl. klin. Woch.,* Nov. 4, 1901) points out the rational therapeutic relation of the hot-air douche to these cases. The author presents a series of clinical records showing the value of the hot-air douche (Frey's method) in cases of neuritis, muscular rheumatism, neuralgia, acute gout, angina pectoris, scleroderma, and chronic articular rheumatism.

Surgical Antisepsis by Potassium Permanganate and Hydrogen Peroxide.—If a solution of potassium permanganate is applied to a wound the tissues and organic substances present give up a portion of the oxygen which enters into their chemical composition and manganese dioxide is formed. This is of a brown color. When hydrogen peroxide is similarly used it gives up a part of its oxygen with an intensity which greatly varies according to the composition of the organic matter present. Auche and Tribondeau (*Comptes Soc. Biol.,* Oct. 25, 1901) advocate for surgical use the combined employment of these agents and claim that by such a more powerful bactericidal action is produced than when either is separately used. The permanganate is first applied and manganese dioxide formed. If now the peroxide is employed a chemical reaction is set up in which the peroxide is reduced as before and in addition the MnO_2 is changed to MnO. Thus a larger amount of nascent oxygen

is set free than when either substance is singly employed. As the bactericidal action of these substances is due to the amount of disengaged nascent oxygen and the intensity of the accompanying chemical process, it is readily seen that their combined employment is more efficient than their isolated use. Experimental observations have fully confirmed the theoretical deductions.

Chronic Non-Gonorrheal Urethritis.—It is customary to describe as chronic gonorrheal urethritis cases which last for years with occasional mild exacerbations, although gonococci may be sought for in vain in the urethral discharge. L. WAELSCH (*Prager med. Woch.*, Oct. 24, 1901) contends that such cases are not properly classified as gonorrheal provided due search for gonococci is made without success. In a case cited by this author more than fifty examinations of the urethral discharge were made, and the few bacilli and diplococci found were in every instance readily differentiated from gonococci. The clinical picture of chronic non-gonorrheal urethritis presents the following characteristics: Long incubation period; absence of an initial acute stage or of very acute exacerbations; mild subjective and objective symptoms; absence of gonococci throughout the disease; bad prognosis for cure. In these cases Waelsch found that he could not effect a cure by any of the modern methods of treatment. Germicides, astringents and local mechanical treatment were as unsatisfactory as were medicines given by mouth.

The True and False Tubercle Bacillus.—Until quite recently it has been thought that the peculiar staining reactions and morphology of the bacillus tuberculosis were sufficient to differentiate it from all other micro-organisms. Although the so-called bacillus of syphilis, smegma bacillus and lepra bacillus possess the same morphology as the tubercle bacillus, the fact that the first is decolorized by sulphuric acid and the second by alcohol, while the third stains readily with the ordinary dyes, renders the differentiation between these organisms and the tubercle bacillus absolute. During the last two or three years it has been discovered that certain bacilli found often on grass, in milk, in butter and in wine present staining reactions and morphology practically identical with those of the bacillus tuberculosis. For this reason it has been thought that the time-honored methods of identifying tubercle bacilli by stain and morphology are about to fall into disrepute and become obsolete. A. MOELLER (*C'tlblt. f. Bak.*, Oct. 25, 1901) has made a comparative study of these so-called pseudo and the genuine tubercle bacilli. He shows that while these pseudo-bacilli possess considerable variation in their morphology, yet the same applies to the tubercle bacillus and does not constitute a differential point of value. When grown upon artificial culture media these pseudo-bacilli multiply abundantly in the presence of other organisms, while the tubercle bacilli are grown only with great difficulty, even in pure culture, under the usual artificial conditions. Furthermore, pseudo-bacilli thrive abundantly at room temperature and the bacillus tuberculosis grows only at the incubator temperature. The pathogenesis of pseudo and genuine bacilli for research animals possesses many similarities. The lesions produced by the former are, however, largely exudative in character with a marked tendency to abscess formation, while the production of proliferative changes is characteristic of the latter. As the pseudo-organisms have been repeatedly found in the throats and mouths of human beings, it is evident that great care must be exercised in differentiating them from genuine tubercle bacilli.

X-Ray as a Depilatory.—The latest method of depilation before the profession is that effected by the X-rays. DAVID WALSH (*Lancet*, Nov. 2, 1901) used this method of removing superfluous hairs after July, 1897, when it was found that "focus-tube dermatitis" resulted in temporary loss of hair from the surface of the skin. Exposure to the X-ray made from ten to fifteen minutes with the tube a few inches from the skin causes the hair to fall out in about ten days. Still this does not destroy the bulb of the hair, and in two or three months the growth has returned. The writer has practised very successfully a combination of the X-ray and electrolysis, which is recommended in preference to electrolysis alone as a permanent cure for this condition. The region of the skin which is to be depilatated is exposed to the X-ray bulb as just described and at the end of ten days the electrolysis needle is placed in the pit made by the removed hair and allowed to remain there for twenty or thirty seconds. This method means that a large number of electrolytic punctures must be made in a small area. Sometimes a second exposure to the focus tube has to be made before the hairs become loosened. The author holds that this combined method shortens the process of depilation, but, like pure electrolysis, it should not be undertaken unless the patient has enough resolution and patience to undergo the requisite treatment.

Relation of Trauma to Tumors and Inflammation.—Just exactly what causal relationship exists between injury and the development of tumors and inflammation has always been a mooted question. B. JORDAN (*Münch. med. Woch.*, Oct. 29, 1901) has investigated the literature very extensively and finds that in not one single case of carcinoma can trauma be considered the real inciting cause, although to a superficial observer the history might prove conclusive. The evidences are somewhat stronger with sarcomata, and it is especially in cases of growths which develop about the extremities and at the site of callus from previous fractures that a previous injury may be held responsible. It is also probable that the various benign tumors, especially the bony one, are occasionally of traumatic origin. In order to have the relationship undoubtedly established the original injury must be observed and accurately localized by a physician; the tumor must correspond exactly to the

site of the injury; the time between the trauma and the appearance of the tumor must agree with the usual time of development of the latter, and, lastly, there must be evidence that tumor-development was not already in progress independent of the injury. Concerning the first statement, it is well known that the patient's own remarks are notoriously untrustworthy. With reference to the third, it is impossible to determine a definite time within which a tumor must develop, since this is apt to vary within very wide limits. As far as tuberculosis and acute osteomyelitis are concerned, there is little doubt that a blow or a fall may so diminish the vitality of the part that germs already circulating in the blood will readily settle there.

Remarks on Infantile Scurvy.—In most of these cases the diagnosis is not hard to make, but where the classical symptoms are wanting or only one is present it may be safe to give some definite answer if asked for a diagnosis, says J. McCAW (*Brit. Med. Jour.*, Nov. 2, 1901). The writer refers to a case which was brought to him; the child had been fed upon condensed milk and patent cereals for ten months. The baby had vomited blood and there was a slight diarrhea in which there was altered blood. There was complete absence of other symptoms. Orange-juice, one dram every two hours; small quantities of whey and cream, at varying intervals, with a teaspoonful of beef-juice every four hours, comprised the treatment. At the end of one week the whole condition was changed and the child soon recovered completely. Fowler's solution was given during the rest of the treatment.

Albuminuria.—Many persons are still fit subjects for life insurance despite the presence of albumin in their urine, according to B. J. STOKVIS (*Klin. therap. Woch.*, Nov. 3, 1901). In order to separate the truly renal from the extra-renal cases, a microscopical examination is essential, yet even the presence of casts does not absolutely prove a true kidney lesion. In this, the more permanent character of the albuminuria, the involvement of other organs and the presence of a number of other symptoms are to be looked for to assure the diagnosis.

Suprarenal Gland in Ophthalmology.—Preparations of the adrenal gland are very valuable in various affections of the eye, according to JOHN H. BOWN (*Brit. Med. Jour.*, Nov. 2, 1901). The writer prefers the suprarenal of the pig, as preparations of this seem to be more staple. It is used in the proportion of twelve grains to the dram. Stronger solutions may be used with impunity. In cases of photophobia with hyperemic eyelids and mucopurulent discharge, complete recovery will take place in four days. In hay asthma an occasional drop in the eye, in combination with a nasal spray of the same drug, the relief surpassed that obtained from cocaine. The eye-strain from hypermetropia is greatly alleviated and the patient may continue the use of his eyes without discomfort. One case of idiopathic hemorrhage into the vitreous, of a recurrent character, occurring in both eyes, was treated with the suprarenal extract and the oozing seemed to stop remarkably sharply.

Tests for Butyric and Acetic Acids in Stomach Contents.—These acids when present to any degree in the stomach contents mean fermentation, and hence their detection is of great importance. The tests for these acids have previously been very complicated and impracticable. M. I. KNAPP (*Med. Rec.*, Nov. 16, 1901) describes a very simple method of detecting these acids. One c.c. of the filtered stomach contents is extracted with about five c.c. of ether by shaking and allowing to stand for a few minutes. One drop of a ten-per-cent. solution of perchloride of iron is added to two c.c. of water. This gives it a faint yellowish tinge. A part of the extract is then floated on the top of the iron solution. If lactic acid is present a sulphur yellow ring appears; if butyric acid, an orange color, and if acetic acid is present a rusty-colored line appears between the two fluids.

Diseases of Uterine Appendages.—These are usually due to extension of morbid conditions elsewhere, writes A. P. CLARKE (*Amer. Jour. of Obstetrics*, Nov., 1901), and can often be cured without radical operation. A catarrhal or gonorrheal endometritis may set up a salpingitis or ovaritis, and all these affections may often be cured by dilatation and curettement of the uterus followed by local treatment. Applications of ichthyol-glycerin, repeated hot douches, soothing suppositories, counterirritants, may all be of use. Circumscribed hyperemia or hematoma may take place in the ovary from sudden suppression of the menstrual flow, and scarcely requires any treatment except rest and the avoidance of excitement. Oophoritis generally is connected with the puerperal state; it may result from laceration or septic infection of the cervix, or from large abscesses of the vaginal wall or the pelvic connective tissue. Affections of the cecum, appendix, rectum and anus appear as causative factors often enough to demand careful examination of these parts. Diarrhea and dysentery have been accompanied by much ovarian pain at menstruation, which disappeared with the intestinal trouble. Ovaritis is also caused by malposition of the uterus. Tumors of the uterine body, sometimes, are the cause of much hyperemia and flooding at the menstrual period. The ovary may be contused in labor by partial prolapse into the pelvis. Tubo-ovarian cysts, ovarian hydrocele, hydrosalpinx and pyosalpinx are common enough. Gonorrheal or purulent salpingitis is accompanied by adhesions to the surrounding parts, or contraction or closure of the lumen of the tube. This may cause dysmenorrhea and sterility; nevertheless, many cases of salpingitis terminate favorably without operation.

Pathology and Treatment of Migraine.—The lives of many people are so seriously marred by frequent recurrences of severe headaches that successful treatment of this most annoying condition becomes of vital importance to the physi-

cian. The individual attack is usually comparatively short and self-limited, so that various drugs may relieve the distress, but to be able to so change the constitution and habits of the patient that attacks of migraine cease to occur is, indeed, seldom realized. W. H. THOMPSON (*Med. Rec.*, Nov. 16, 1901) believes that too little attention is usually paid to these unfortunate patients, whose lives are often most miserable. Migraine can not be classed among the degenerative nervous diseases, for it is chiefly a malady of youth and of the prime of life, decreasing in old age. There are whole classes of people who seldom if ever are afflicted with it, and these include nearly all those whose occupation calls for physical work in the open air. Clergymen, students, shopgirls, professional men and housewives are especially prone to the disease. The secretion of bile is considered by the author as an important factor in the determination of migraine, and a sedentary life, with an inactive diaphragm, abdominal muscles and a sluggish circulation, certainly tends to obstruct the normal flow of this secretion. Imperfect digestion and chronic constipation naturally result. Many of these products of imperfect digestion are nerve poisons, and it is one of the important liver functions to destroy these gastro-intestinal nerve poisons. Measures must be devised in each case to cause as fully as possible, in accordance with modern civilization, habitual activity of the portal system. All severe cases are chronic dyspeptics with chronic constipation. Five grains of blue pill with a saline in the morning is a weekly prescription to be kept up for months. One to two drams of sodium sulphate with ten grains of sodium salicylate are to be taken in hot water every morning. Before each meal, a pill is prescribed of one-twentieth of a grain of bichromate of potash with three grains of bismuth subcarbonate. After meals intestinal antiseptics, such as naphthol, bismuth or ammonium benzoate, may be given. A good prescription is:

℞ Sod. sulpho. carbol. .gm. 0.30 (gr. v)
Kal. permangan ..... 0.06 (gr. i)
Beta naphthol ..... 0.06 (gr. i)

To be taken after meals and at night. For severe attacks of migraine the fluid extract of ergot in dram-doses, with elix. cinchona in water by stomach or rectum, is perhaps the most certain agent. The patient should lie perfectly still until all pain ceases and the dose may be repeated in an hour or two. Ten grains of lactophenin and two grains of caffeine citrate are also a valuable combination.

Malpositions of the Uterus in Unmarried Women.—A malplaced uterus may sooner or later, writes H. E. HAYD (*Amer. Jour. of Obstetrics*, Nov., 1901), offer an obstruction to the menstrual flow, either on account of the flexion which exists or the congestion, and associated thickening of the lining membrane. Besides dysmenorrhea, such obstruction may be accompanied by severe backache and bearing-down pains, pains in the groins, and reflexes, such as nervous dyspepsia, irritable bladder, hysterical aphonia, fits, clutching at the throat, irritable heart, pain in head or neck, and various visual defects. A rectal examination is often quite sufficient for diagnosis, and young girls should not be permitted to suffer on the score of modesty. A pessary can do very little good in these cases and its introduction is painful. Tampons, electricity or other non-operative measures afford only temporary relief. The author's treatment is to perform dilatation and curettage and the Alexander operation, which does not interfere with subsequent pregnancy.

THERAPEUTIC HINTS.

Acute Alcoholism.—A formula recommended by J. M. Anders is:

℞ Sodii bromidi .....gm. 30.0 (℥i)
Tinct. capsici ..... 4.00 (℥i)
Tinct. digitalis ..... 2.0 (℥ss)
Elix. simplicis ad..... 60.0 (℥ij)

M. Sig.: A teaspoonful every two or three hours in water.

Thrombosis of the Femoral Vein in Typhoid Fever.—This is best treated by elevating the part and keeping it at perfect rest. The following ointment may be applied along the course of the vessel three times daily:

℞ Ung. ichthyol,
Adeps lanæ hydros. aa.. 8.0 (℥ij)
Ung. belladonnæ .....16.0 (℥ss)

After the swelling has subsided an elastic stocking should be worn for a couple of months.—J. M. ANDERS in "Practice of Medicine."

Retroversion of the Womb.—A retroverted womb uncomplicated by disease is treated by M. ROSENWASSER (*Amer. Jour. of Obstetrics*, Nov., 1901) by replacement and the support of a pessary. If complicated by diseased womb or impaired pelvic floor, the pessary should be preceded by a plastic operation. If complicated by aggravated prolapse simultaneous plastic and suspension operations should be done. If the womb is fixed, treat for pelvic inflammation. A suspension operation, in ordinary conditions, should be resorted to only when mechanical support and the plastic operation have failed.

Uterine Fibromyomata.—In the treatment of metrorrhagia accompanying fibroids, H. D. INGRAHAM (*Amer. Jour. of Obstetrics*, Nov., 1901) has tried thyroid extract and desiccated mammary gland without much benefit. Ergot and hydrastis he finds of use and stypticin the best drug of all. The curette may be successful, but is a dangerous remedy. Electricity is safe, but has little value. When pregnancy occurs, with a large, rapidly-growing fibroid situated below the fetus in the pelvis, and nearly filling that cavity, there is nothing to be done but hysterectomy.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

SATURDAY, NOVEMBER 30, 1901.

NEW YORK MEDICAL RECONCILIATION.

AT the regular monthly meeting of the Medical Society of the County of New York, held last Monday evening, a movement looking to the reconciliation of the two medical organizations in New York State and County which at present claim the divided allegiance of New York physicians was happily initiated.

Dr. St. John Roosa proposed and the County Society unanimously adopted at the suggestion of the incoming President of the Society, Dr. Van Fleet, a resolution to the following effect: That a Committee of Five be appointed by the President of the Medical Society of the County of New York to meet and confer with a similar committee to be appointed by the New York County Medical Association in order to arrange the details of harmonious affiliation of the two organizations in County and State.

This resolution, let us hope, will prove the initial step in the reconciliation of elements that have always been a unit in their purposes of benefit for the medical profession, who have been coming ever closer together in recent years, as regards the best methods of accomplishing their common purpose and have been kept apart only by traditional differences with very little basis of real divergence of opinion.

Since the President of the American Medical Association declared last year that the question of the Code was not a vital element in the binding principles of that Association, there has been no good reason for the existence of two separate medical organizations in New York. It was on the question of the Code that the New York Medical Society was cut off from the American Medical Association. Now, that the National Association has come around to New York's way of thinking, it is preposterous further to exclude men who were ahead of their time, but were pioneers for the right.

A united medical profession in this country can accomplish great things. The fact that the profession of the powerful Empire State has been divided against itself has detracted much from all efforts at National legislation. A favorable opportunity seems to be presented now for the repair of the breach in the ranks that has weakened all such efforts. No sacrifice should be spared on either side to succeed in the beneficent purpose. Certainly the New York State Medical Association should be willing to do anything and everything for the reconciliation with the elder sister organization that will after nearly a score of years enable a united medical profession in New York to wield all the influence it should have. It would be easy at the present time to delay for a good while, perhaps, the benefits sure to accrue from reunion. It is to be hoped that no mere technical quibbles or political motives will be allowed to interfere with the good purposes proposed. The medical profession, not of New York State alone, but of the whole country, will watch jealously the proceedings in this matter. They will resent any unworthy or pusillanimous excuses that may be supposed to serve as pretexts to hinder reconciliation. A better time than the opening year of the new century could not be found for so hopeful a movement. May the year not die before we shall be able to state that the preliminaries of reconciliation are arranged, and that the assurance of professional union and strength is at hand.

HONOR TO DR. T. GAILLARD THOMAS.

"No company can be more amiable than that of men of sense, who are doctors," and doubtless a more amiable and more brilliant company of men could not be found than those that dined at Sherry's last week in honor of Dr. Thomas'

seventieth birthday. The three birthday dinners held recently, Dr. Jacobi's Festschrift, the Virchow celebration and this feast of love and reason, indicate the tendency among scientific men to pay tribute to those whom they esteem, by the expression of their good-will and admiration.

Dr. Thomas himself put it succinctly in his remark that the reward for which he had been working for fifty years was the esteem and approbation of his brothers in the profession. Only a physician can realize how single of purpose and high of mind another physician must be to win this universal approbation unmixed with envy or jealousy; and there is doubtless no keener sense of gratification to a man who has been true to his ideals in serving humanity than to feel that his brother practitioners, who know that he was tempted in all points like as they were, hold him honorable and unselfish, as well as a master in their art.

The tangible but impersonal honor of bronze and marble to link one's form and feature with one's name is inspiring to posterity; but, we feel, not so inspiring nor gratifying to the great man himself as is this growing custom of crowning him when ripe in years with garlands of friendship.

PROPHYLAXIS OF VENEREAL DISEASE IN NEW YORK CITY.

The special Committee of Seven, selected earlier in the present year by the Medical Society of the County of New York to prepare a report on the subject of the prophylaxis of venereal disease in this city, presented the result of their labors at the meeting on November 25th. The report, of which a very complete summary will appear in the next issue of the Medical News, is a model of painstaking effort, of judicious discussions, of suggestive collation of ideas from many sources, and of very practical purposefulness. It reflects great credit on the Committee which have had the matter in charge and especially on the Chairman and Secretary on whom most of the work devolved. The report comes very opportunely, now that the recent change in the political complexion of the city administration makes it possible that medical suggestions on this important subject will be looked to with more care than otherwise would be the case.

With regard to the question of decreasing the dissemination of venereal diseases by direct legal regulation of prostitution the Committee agree that it is out of the question. Not only is the temper of our people very much opposed to what they would inevitably consider compounding vice, but also legal regulation has in the countries where it has been tried proved almost universally a failure. It is much more probable that the laws regulating prostitution will be repealed in the countries where they now exist than that any other countries shall join the movement which many former advocates now admit to be doomed to fail.

With regard to segregation of prostitutes in one part of the city as a means of checking the evil it engenders, moral and physical, the Committee are of opinion that this, too, cannot be accomplished under present conditions. It can scarcely be done without some approach to legal toleration of the evil. This will inevitably seem to be a quasi authorization and will meet with decided opposition from a large class of our people. With regard to domiciliary segregation, however, this question is different. Moral and immoral tenants must not be allowed to occupy the same premises. Above all, families with children must be protected from contact with and contamination by immoral neighbors. For this no special legislation is required. The enforcement in moderation of existing laws will accomplish the purpose very fully. The Tenement House Commission is at present doing excellent work with regard to the most serious features of domiciliary contamination and their efforts must be encouraged. The Committee are agreed that all external signs of the presence of evil must be rigorously suppressed. All red lights, street or window solicitation, indecent exposure, etc., must be completely suppressed.

With regard to the enaction of a penalty for the transmission of syphilis, while admitting the difficulties in the way of enforcement of the law, the Committee feel that the presence of such a law on the statute books would be of great educative value, as well as occasionally enabling justice to be meted out to a criminal. As it is mainly the younger prostitutes who convey syphilis, the enactment of a law raising the age of consent is suggested. Procurers not only do a great moral evil, but also a great physical wrong since their victims are destined, not only to become affected themselves with venereal disease, but to become foci of infection for others. The laws in this matter must be enforced to the utmost and the public conscience aroused by every possible means to encourage the detection and the unmitigated punishment of these criminals.

The Board of Health as at present constituted has not only the right, but the duty, to control contagious diseases. There is no good reason why their efforts should be limited to the less widespread and less dangerous diseases of this class. Venereal diseases are eminently contagious and are calculated more than any others to undermine the health of the community and especially of its most valuable members, young adults. The Board of Health must be aroused to a sense of its responsibility in this matter and all possible measures for the protection of health must be enforced. This seems the most natural way to get at the gradual suppression of the evil. Patience will be needed for the accomplishment of lasting good.

Meantime there remains the educative influence that the medical profession can exert upon the community. The declarations with regard to the dangers of venereal disease and the difficulty of its cure must be very straightforward. Young men must be plainly told that sexual continence is consonant with health and sexual indulgence absolutely unnecessary. The necessity for prompt treatment must be insisted on and public opinion must be brought to understand that every dispensary and hospital receiving public aid should provide treatment for venereal diseases. On the other hand, the impression that venereal diseases are easy of cure must be removed. All advertisements of secret sure remedies, of special infallible prescriptions and of venereal quacks, who never fail to cure, should be absolutely forbidden, not only in the public prints, but also in the form of posters in public places.

As can be seen from this brief review nothing of importance has been omitted in the Committee's report. It contains no startling suggestions and no radical opinions. It is very happily temperate and judicious. The report can scarcely fail to do great good by calling public attention to conservative medical opinion on the various phases of this important question. We hope that it will be given due publicity and foresee a partial accomplishment of its highest purpose in its own thoroughly deserving educative influence.

IT IS noteworthy that in States where interference with scientific experiments is prohibited to societies for prevention of cruelity to animals, much less commercial cruelty to animals is permitted than in States where "humane" societies levy on the people for antivivisection propaganda. Chicago, for example, in its brutal treatment of horses and of cattle at the stock-yards, presents a disagreeable contrast with New York, whose Bergh Society is forbidden to interfere with scientific experiment by its charter. Despite the money annually wasted on the "humane" society, private effort must battle against overloading and brutality toward horses. The leaders in the Chicago "humane" society devote their efforts chiefly to battling against vivisection, which has simply humanity and science in view, since warfare on commercial cruelty means loss of revenue and social status.

ECHOES AND NEWS.

NEW YORK.

New Health Institute.—The Health League of New York City was incorporated at Albany, November 21st, with a capital of $150,000, to establish schools and hospitals for the treatment of the sick through the "nature cure," as opposed to treatment by drugs and medicines, and to manufacture prepared foodstuffs, clothing and apparatus.

Woman's Hospital.—The Woman's Hospital in the State of New York, celebrated at its annual meeting, held recently, its forty-sixth anniversary. This hospital, the first of its kind, was founded for the treatment of gynecological diseases exclusively, and in its peculiar field has won much success, largely due to the disinterested services of the attending physicians and surgeons. For some years the Board of Trustees have been anxious to build a more modern hospital, and subscriptions to the amount of $370,000, $32.000 of which has been received during the past year, are now in the hands of the treasurer. At least half a million dollars will be required for the new building; but it is probable that the funds now in hand will be considered sufficient to warrant commencing the building the coming year.

Appointment of Dr. Jelliffe.—Commissioner Keller has ordered the appointment of Dr. Smith Ely Jelliffe as Visiting Neurologist to the City Hospital, the position made vacant by the resignation of Dr. Frederick Peterson when he was appointed Commissioner in Lunacy.

PHILADELPHIA.

Smallpox Situation in Philadelphia and Camden.—The smallpox outbreak in Philadelphia seems to show the effect of the wholesale vaccination employed, over 800,000 residents having been vaccinated during the summer and fall. Last week's report is 46 new cases and 7 deaths. There are now 213 cases in the city. The total number since the first of the year is 655 cases and 97 deaths. In Camden there is a slight increase in the number of cases. The Board of Health investigation to determine the cause of

tetanus in the cases reported last week has not as yet developed anything pointing to vaccination as the cause. In one family two brothers were vaccinated from the same tube of virus. One is very ill from tetanus, the other has shown no signs of that disease. In Burlington ten horses are being inoculated with virus as a test of its purity.

New Fellowship in Pepper Laboratory.—Dr. George Woodward has donated to the University of Pennsylvania $20,000 to endow the "Woodward Fellowship in Physiological Chemistry" in the Pepper clinical laboratory. The work of the incumbent will consist entirely of chemical investigations of disease.

Gift to Jewish Hospital.—Meyer Guggenheim of New York has made a gift of $60,000 to the Jewish Hospital Association for the erection of a building for the treatment of private patients. The income from the building is to be devoted solely to the charitable purposes of the Jewish Hospital.

Obituary.—Dr. Philo H. Banks of Mifflintown, Conn., died in New Orleans, November 23d, of typhoid fever. Dr. Banks, whose family is prominent in Juniata County, was a recent graduate of Jefferson Medical College. He had been in the employ of the British Government Transport Service between New Orleans and South Africa and contracted the disease on his last voyage.

Lupus Treated by the X-ray.—At a recent clinic at the Jefferson Hospital Dr. J. Chalmers Da Costa exhibited a patient with a patch of lupus at the base of the nose. The diseased area had been exposed sixteen times, twice a week, to the action of the X-ray, the remainder of the face being protected by a leaden mask. This treatment resulted in an apparent cure, but in a short time after the exposures were discontinued the ulcerative process again began. The treatment is now to be repeated.

New Laboratory Opened.—The Philadelphia Clinical Laboratory has been incorporated under the direct control of women chemists. Milk, gastric contents, urine, etc., will be analyzed and examinations made of tissue, blood, sputum, etc. Mary Pennington, Ph.D., Director of the Chemical Laboratory in the Woman's Medical College, is president of the newly-incorporated institution.

Sixty-five Physicians in One Block.—The statement is made that within the radius of four blocks in the central part of this city is located more than one-seventh of its medical population. In one block alone, Chestnut street, between Eighteenth and Nineteenth, there are sixty-five physicians. This surfeit is explained partly by the fact that the area mentioned is almost the center of the city. Another factor is that it is the location of many of the most prominent practitioners and younger physicians have of late years been attracted thither.

CHICAGO.

Contagious Disease Hospital.—Plans are on foot for a hospital where contagious and infectious diseases will be exclusively treated. For the purpose of giving information and collecting funds, an office has been opened. A charter has already been obtained.

Antitoxin in Diphtheria.—It is said that an increase of fully one-third in the number of deaths from diphtheria in proportion to the number of cases reported has been noted during the past two weeks. The medical inspectors of the Department of Health report a distrust of the use of antitoxin, both by physicians and parents, which fully accounts for this result. Such distrust is, in the judgment of Commissioner Reynolds, wholly unwarrantable. He says: "Probably never before in the history of antitoxin has this specific for diphtheria been so safe to use. The deplorable results in a neighboring city furnish no criterion of the method of antitoxin production in general, and the fact that more than 140,000 injections of the remedy distributed by this Department during the past six years without a single such result should reassure those who have been needlessly alarmed."

Norwegian Lutheran Hospital.—Contracts have been let for the construction of a hospital for the Norwegian Lutheran Deaconess Society, which is to comprise several buildings from one to three stories in height, at a cost of $40,000.

Report of Mercy Hospital.—Improvements in the equipment and additions to Mercy Hospital are described in the annual report just issued. A new amphitheater, buildings for the nurses and a thoroughly-equipped laundry were built during the year. The Hospital was successful in its mission of caring for the sick, and the Sisters of Mercy who manage the institution are satisfied with the condition of its affairs. The financial report shows that $104,395.15 was received during the year. Cash on hand, October 1st, amounted to $1,123.42. The indebtedness of the hospital is $134,609.53. Nearly all of the regular income of the hospital is required to defray the ordinary expenses, and with their report the Sisters of Mercy issue a call to the benevolent.

Opposition to St. Luke's Society.—Erskine M. Phelps, C. D. Peacock, Murray Nelson, and Dr. E. C. Dudley have joined in a petition to the Health Department against the issuance of a hospital license to this society. The petition declares that the society conducts a hospital for the treatment of patients suffering from the liquor and morphine habits. It states also: "That the method of conducting and operating this hospital from the nature of the ailments treated therein has been and must of necessity be a nuisance in law; that patients suffering from alcoholism are daily carried up the front steps of the hospital by the attendants, many of such patients being intoxicated to the point of helplessness, while others are suffering from delirium

tremens, and after being overpowered by the attendants, are carried screaming, cursing, and struggling up the stairs into the hospital; that frequently patients suffering from delirium tremens have run screaming about the neighborhood." The hospital is not the same as St. Luke's Hospital.

Morphine and Allied Drug Habits.—Dr. David Paulson, at a meeting of the Chicago Medical Society, held November 20th, said that the alarming increase in recent years in the number of neurotic individuals is producing a proportionate increased demand for sedative drugs. The very fact that almost every issue of popular magazines contains nearly a dozen alluring advertisements of various remedies or institutions purporting to cure these drug habits is a strong indication that there are plenty of victims to patronize them. In order to cure permanently a victim of one of the drug habits, either the patient must be built up into such a state of health that he will have no occasion in the future to depend upon the drug, or else he must develop a fortitude to bear suffering. Unless one or the other of these conditions is established in the cure, the time spent in most instances is simply thrown away. Some idea can be had of the author's treatment by narrating one of the several cases reported by him. Physician; male; smoked ten cigars daily; used alcoholic stimulants moderately; used four grains of morphine daily; had been using morphine occasionally for many years, but constantly during the last four or five years; also used several grains of cocaine, definite quantity not known. He was cut down to one-half grain of morphine the day after consulting the doctor. Treatment first day: Warm electric baths; fomentations to the spine; massage; rested quietly seven hours; slept two hours. Second day: Fomentations to the spine, stomach and liver; warm electric baths; massage; very nervous and sick; severe attacks of vomiting; injected $^1/_{150}$ grain of atropine; slept between two and three hours. Third day: Warm electric baths; massage; fomentations to the spine, stomach, abdomen and head; warm enemata; slight vomiting attack; rested and slept between five and seven hours. Fourth day: Warm electric baths; Swedish shampoo; massage; dry hand rub; warm enemata; restless; slept between two and four hours. Fifth day: Warm electric baths; felt better; slept between five and seven hours. Sixth day: Warm electric baths; massage; fomentations to the spine; read newspapers; walked about the room; rested several hours; slept a few hours. Seventh day: Hot electric baths; wet sheet pack; cool sponge; rode in street-car; strength good; mind clear; slept between five and seven hours. Eighth day: Similar treatment as before; wakeful and restless; slept but a few hours. Ninth day: Spent most of the day outdoors; took two doses of sulphonal on his own responsibility; slept from five to seven hours; spray in the morning after rising; felt quite well. Tenth day: Sedative treatment in bathroom; dismissed his night nurse; took sulphonal, but did not sleep. Eleventh day: Took sedative treatment in the bathroom; ate a few apples; and slept one hour and a half. Twelfth day: Tonic treatment; slept six hours. Thirteenth day: Same treatment; slept seven hours. Fourteenth day: Same treatment, and slept from four to six hours; gained strength. Fifteenth to the twenty-fifth day: Gained ten pounds; then went away feeling well pleased. One year later, a private letter from patient stated that he was well, happy, and attending to a large practice.

Infectious Origin of Purpura Hemorrhagica.—Dr. A. W. Schram reported the case of a patient, F. W., a barber, twenty-one years old, with previous negative personal and family history, who was suddenly taken sick with general malaise. On the fourth day of illness hemorrhagic spots appeared on the limbs, and in the course of two weeks the patient's body was almost entirely covered with purpuric spots. There was bleeding from the gums, but no bleeding from nose, and no blood in the urine or feces. In the third week of sickness, the entire left side of face became paralyzed, involving the oculo-facial group, but no paralysis of tongue or palate. The chest was negative. Liver and spleen enlarged. Temperature 102° to 105° F. Pulse 120 to 150. Axillary, cervical and inguinal glands enlarged. Blood: Red cells varied from 2,280,000 per c.mm. to 1,370,000. White cells varied from 16,000 per c.mm. to 4,000. Hemoglobin, 22 per cent. to 12 per cent. Differential count of white corpuscles gave 90 per cent. small mononuclears or lymphocytes. Cultures from blood thirty-six hours antemortem gave pure growths of staphylococcus aureus on all media inoculated.

Pathology of Purpura Hemorrhagica.—Dr. W. H. Rubovits said in this case the hemorrhages and hemorrhagic infarcts in unaccountable numbers were revealed at the autopsy in the liver, spleen, pancreas, kidneys, suprarenal bodies, lungs, heart and pericardium, pleura, peritoneum, synovial membranes, muscles, adipose tissue and skin. A few petechiæ were found in the meninges of the brain. The brain, intestinal and vesical mucous membranes were entirely free from hemorrhages. If sections are made through tissue in which no macroscopical hemorrhage has taken place, the cause of the bleeding may be ascertained. Minute blood-vessels were found in the spleen in which a distinct rupture had occurred, apparently just before death, because only a small amount of blood had escaped, and therefore the details in the tissue changes were unobscured. Another factor to be considered in relation to the hemorrhages in purpura is the formation of very large numbers of minute thrombi and emboli. The alterations in the blood and the circulation in the blood of large numbers of micro-organisms, together with the constant degenerations of the blood-vessels which obtain in this disease, conduce to the formation of these circulatory changes. The search for the

pathological changes in the vessel walls revealed the presence of micro-organisms in the circulation. By employing the special methods for staining bacteria in tissues, the cocci were also found in the parenchyma, but in very small numbers in contrast to the large numbers found in the blood-vessels. Notwithstanding the presence of the cocci, the parenchyma of the liver, spleen and pancreas was practically unaltered, and that of the kidneys and lungs showed only slight changes, a diffuse nephritis and bronchopneumonia. Marked hyperplasia of the agminated and solitary follicles of the intestines, with slight alteration, was present. This is the common finding in purpura hemorrhagica, due to the accompanying gastro-enteritis, which is commonly present and usually marks the onset of the disease, as in this case. The changes which were found in the liver have been found in other cases of purpura. It is the only finding which differs essentially from an ordinary septicemia. Letzerich says that just as we first feel for an enlarged spleen in malaria, so should we first look for an enlarged liver in purpura. The postmortem record of this case states that the liver was of a pale-brown color, firm in consistency, moderately increased in size, and that on section the markings were very distinct. The hemorrhages were very numerous. Microscopically, the interlobular connective tissue was found to be greatly increased in amount, and to contain many leucocytes and large numbers of the minute thrombi which have been referred to. The parenchyma was in a healthy condition. The changes correspond to an interstitial hepatitis.

GENERAL.

Medical Society of City Hospital Alumni (St. Louis).—This Society met Thursday, November 21st. Dr. W. C. Mardorf read a report of an Unusual Case of Oïdium Albicans, and Dr. L. Bremer read a paper on Artefacts of Blood Examinations.

St. Louis Medical Society of Missouri.—Two Cases of Tetanus from Diphtheria Antitoxin; Recovery; Presentation of Cases, was the title of a paper by Dr. T. A. Martin, read before this society November 23d.

Smallpox in Kentucky.—Smallpox has been costly in lives and money to Kentucky. All except nine of the 119 counties in the State—those nine being remote from the main lines of travel—have had more or less experience with smallpox during the present epidemic, covering a period of nearly four years. A total of 394 distinct outbreaks is reported, eighty-five of these being fresh importations from other States. In all 11,269 cases are reported, with 184 deaths, a mortality of 1.63 per cent. Special hospitals were erected in sixty-three counties and municipalities, but probably a majority of cases outside of the large cities and towns were isolated and treated in their homes. Much of the expense might have been avoided and many of the lives lost might have been saved had heed been given to the warnings urging vaccination.

St. Bartholomew's, London.—The students at St. Bartholomew's Hospital, London, will in future receive clinical instruction in insanity at St. Luke's Hospital. Hitherto they have had to go considerable distance to one of the County Asylums, involving an appreciable loss of time in transit and some inconvenience.

Virchow Institute in Russia.—The Russian Government has decided to establish a Virchow Institute in Moscow.

Anniversary of Leopold.—The one hundred and fiftieth anniversary of the founding of the Imperial Leopold Caroline Academy of Sciences, the oldest scientific society in Germany, will be celebrated at Halle on January 1st, 1902.

Medical Mayors in England.—That medical men make most efficient public officers is proven by the number of physicians serving as Mayors of various towns throughout Great Britain; one of them, Dr. J. M. Hughes, of Ruthin, having recently been re-elected for the sixth time, and several others are serving extended terms.

Æsculapian Medicine.—At the recent Pan-Hellenic Medical Congress, held at Athens, Mr. P. K. Avadias, Inspector-General of Antiquities in Greece, stated that, contrary to tradition and general belief, the temples of Æsculapius at Epidarrus, Crete and Rome, were not originally schools of medicine, nor hospitals, nor were the priests in any sense of the word physicians. The practice of medicine had its origin in folk-lore, and was at all times independent of religion. The first physicians were called Asclepiadæ; but the term is not believed to indicate any connection with, or succession to, Æsculapius. Eventually, however, the temples of Æsculapius became the resort of the sick and diseased, who were ministered to by the priests, under the belief that the cases which were treated according to the then established rules of medical practice were under the direct care of the god Æsculapius; and the patients were therefore expected to submit with religious faithfulness. What we now recognize as suggestion played an important part in the treatment; and detailed histories of the cases so managed would make interesting reading at the present day.

St. Mary's Hospital.—The new hospital of St. Mary's, Islington, London, has begun active service with over 600 beds occupied. This infirmary is situated in the center of a thickly-populated district, the inhabitants of which are none too rich in this world's goods. It is to be regretted that the great mass of clinical material thus aggregated is not available for teaching purposes.

Progress of Plague.—Eighty-five cases of bubonic plague with fifty deaths were reported from the island of Mauritius during the week ending November 7th. The epidemic in Egypt is about stamped out; but it is still perniciously active in India. Glasgow is now considered free

from the plague; and no fresh cases were reported in Liverpool during the week ending November 9th. A curious case occurred in this latter city. A boy was admitted to the hospital suffering from enlarged glands in the groin, supposed to be due to an injury received at football. The fluid from the glands was examined and found to contain plague bacilli. The source of infection could not be traced; nor was it found that the boy had spread the infection in any way.

Epidemic of Scarlet Fever in England.—Scarlet fever was found to be epidemic in several districts, some widely separated, in London. Inquiry elicited the fact that the milk supply of the affected districts was derived from two local vendors, and through these latter the source of infection was traced to a case of scarlet fever in the family of a Staffordshire farmer. The output of milk from this farm was stopped, with the result that the number of cases of scarlet fever in the London districts promptly decreased.

Italian Hospitals.—One fact which is painfuly apparent to Americans traveling in Italy is that, while Italian medical men are well advanced as scientists they have not made their influence felt to any appreciable degree in the matter of hospitals or general sanitation. The average Italian hospital is, from an American point of view, incredibly neglected and mismanaged, while the best of them are open to severe criticism. As to the care of the sick in their homes, it is, with occasional exceptions among the upper classes, clearly medieval, even to the point of touching one's sense of humor when one sees modern science abruptly challenged and called to a halt by some queer survival of superstition and prejudice. It is equally evident that little progress can be made in these directions without the coöperation of women and of a properly organized body of trained nurses. Private patients, as well as public hospitals and asylums, have been, in the past, left as a matter of course, and indeed of necessity, in the hands of the various nursing sisterhoods of the Roman Catholic Church, and these, while they deserve full credit for unselfish devotion to their self-imposed duties, are, it must be admitted, if measured by modern standards, altogether unequal to the demand upon them. The few foreign nurses who have established themselves in the large cities find employment almost exclusively among their own country-people, and have little or no influence beyond the sickrooms of their patients. But in Naples, Miss Turton, an English woman, and Miss Baxter, a graduate of the Johns Hopkins Training School, have obtained a provisional footing and are, in the hospital wards which have been put under their care, initiating an experiment which already promises a fair measure of success. Miss Baxter is training Italian women for nurses, and, although she is handicapped in many ways, as can easily be understood without going into details, reports favorably upon their fitness for the work. Miss Turton, going from Naples to Florence, has opened a "Casa di Cūra," No. 48 Via Bolognese, for private cases, and there has her own training school, organized, as she herself says, "on English and American lines." This little hospital is well fitted up, delightfully situated, and provides all that is necessary for acute illnesses and operations, while travelers needing rest or special treatment can find those desiderata supplemented by most attractive surroundings.

Industrial Sanatorium in Colorado.—The Rocky Mountain Industrial Sanitarium, organized by Denver professional and business men last spring, is now in operation. On a ten-acre tract, five miles from Denver, fifteen or twenty patients in the early stage of consumption are virtually taking care of themselves. The rules of the institution compel a continuous outdoor life to be maintained summer and winter. Each patient is provided with a roomy tent, plenty of warm clothing and blankets, and a small stove to be used only in extremely cold weather. Experience has proved that with proper food and clothing, and a life in the open air and sunshine, artificial heat is unnecessary, and becomes absolutely unbearable to the patients, who without exception are gaining rapidly. The hope of the physicians and others interested in the enterprise is to form a colony of all consumptives who come to Denver, and thus take them off the streets of the city, and out of the hotels and boarding-houses, where they could never recover, and where they are a constant menace to the public health. While no one is allowed to profit, the institute must be self-supporting. The coöperative idea has already been put into force, for many of the patients are supporting themselves wholly or in part by doing the work on the premises. Margaret S. Dunne, who received high commendation for her work in army hospitals during the Spanish War, is the superintendent.

New Jersey State Hospital.—The new building of the New Jersey State Hospital was formally opened on the 21st inst. by Governor Voorhees. Governor-elect Murphy made an address.

Health of Cuba.—The report of Dr. W. C. Gorgas, U. S. A., Chief Sanitary Officer of Havana, says that the most prominent feature of the statistics for October is the fact that there have been no deaths from yellow fever in Havana, and not a single new case. It will be seen in the body of the report that three cases are reported, but these three cases were taken sick in September and carried forward into October. It will be seen that October, on the average, in the past ten years, has been one of the severest months for yellow fever. The maximum number of deaths from yellow fever since 1889, for this month, occurred in 1896, when there were 240 deaths; the minimum, in 1899, when there were 25 deaths; the average, 66.27 deaths; this year, no deaths and no cases. Last year, 1900, there were for October 308 cases and 74 deaths. This result adds another month as a practical demonstration of the truth of the mosquito-theory of the transmission of yellow fever. The results attained are

evidently due to disinfection on the lines commenced in February, as directed by the Military Governor with a view to killing infected mosquitoes. It has only occurred a few times since yellow fever became endemic in Havana, some century and a half ago, that an October day (and certainly never two successive days) has passed without a death from yellow fever. This year the whole of October was passed without a case or a death. This cannot be chance and cannot be entirely due to the general sanitary improvement. It might be considered a matter of accident, if the yellow fever record for October were simply slightly lower than the minimum for past years, and if the preceding months had been about the average; but the record for the whole year has been far under anything that has gone before, month after month showing the same good record. The conditions for having yellow fever are certainly as favorable as they were last year, the non-immune population being probably as great as it ever has been in Havana. The only change between last year and this is that since February all mosquitoes have been carefully killed in the neighborhood of every focus, as it has occurred. The infected house and all the adjacent houses, in every case, have been carefully disinfected. The fact that the marked improvement is not confined to October, but has taken place each month since attention has been devoted to the mosquito, is particularly emphasized by considering the yellow-fever year beginning the 1st of April. Since 1889, for these months, there have been on the average 362.16 deaths; the maximum, in 1896, 871; the minimum, in 1899, with 61; this year, 0. The change cannot be due to improvement in general hygiene, from the fact that last year, for this month, there were 74 deaths; this year, none. While there has been improvement in the general hygienic conditions, there could not have been so vast a difference as this would represent. The improvement in general hygiene is measured best by the general death-rate. The death-rate for October, 1900, was 24,33; this year, 1901, 20.17. The yellow-fever phase of the vital statistics is dwelt on, particularly on account of its vast practical importance to the United States. The great truth that yellow fever is transmitted by the "*Stegomyia*" mosquito, maintained by Dr. Charles Finlay against much ridicule for so many years, and recently demonstrated by the Army Board, must soon change all the methods of quarantine in the United States. In Havana, this year, work has proceeded on the hypothesis that the mosquito is the only way of transmitting the disease. Fomites have not been considered in any way. Clothing has not been disinfected nor any effort made, except to kill the mosquitoes which had bitten a sick person, and to prevent any more mosquitoes from biting, after the case was discovered. The results with this plan were so positive that it was soon seen that Havana could not be rid of yellow fever on these lines, but that each focus should be destroyed as it was renewed from the outside. The business interests of Havana were so closely united to those of neighboring towns that it was impossible to quarantine against them without causing entire business paralysis. These towns, early in the year, showed yellow-fever infection and a system of inspection of non-immunes was adopted, whereby every non-immune coming to the city from infected points in the neighborhood was registered and kept under observation for a week. In this way it was possible to get hold of all cases coming from these points—some 15 or 20 cases. Foci have developed in the city in each of the months of July, August and September, but they did not get beyond a few cases, and invariably disappeared after a disinfection, as described.

Obituary.—Henry Spencer Smith, F.R.C.S., Eng., a prominent surgeon of London, died on October 29th. He was the sole surviving charter member of the Royal College of Surgeons founded in 1843.

The deaths of the following eminent medical men are announced: Sir James Wilson Agnew of London, England; Dr. Marcel Nencki, the eminent physiologist of St. Petersburg and later of Berne, Switzerland; Dr. Arthur Koënig, of the Berlin Physiological Institute; Professor Karl Schuchardt, who was for some time assistant to Professor Volkmann at Halle.

Acting Assistant Surgeon Stuart Eldridge, of the Marine-Hospital Service, who was on duty in the office of the United States Consul-General at Yokohama, Japan, died recently. Dr. Eldridge was a native of New York, but had resided in Japan for many years. At the time of his appointment as an officer of the Marine-Hospital Service he was a member of the Imperial Board of Health of the Tokio Health Office and sanitary adviser to the Japanese Government. He was an honorary member of the New York State Medical Society and of the Alumni Association of Bellevue Hospital.

Dr. James P. Jackson died November 23d, aged fifty-seven years. He established the Missouri Pacific Railroad's first hospital at Washington, Mo., and the Wabash and Missouri Pacific's hospital service in Kansas City.

BYWAYS OF MEDICAL LITERATURE.

A SUCCESSFUL PHYSICIAN NOVELIST.

DR. JAMES BALL NAYLOR'S recent novel, "The Sign of the Prophet," promises to repeat the success of his first novel, "Ralph Marlowe." As the latter sold well up into the thousands and was for a time, from the author's standpoint at least, that very desirable success—one of the best selling books of the month, it is evident that Dr. Naylor has found literary occupation worth the while. The doctor is a practising physician at Malta, Ohio, and is, like so many other successful men of our generation, a self-made man. He worked on a farm, went to school at night and in the win-

ter taught school for a while, studied medicine and is now a successful novelist.

A succinct account of his career from his own pen appeared not very long ago in some of the literary journals. He puts it modestly in the third person. "His paternal ancestors," he says, "are Pennsylvania Quakers. His maternal ancestors are Virginia English. The family tree contains besides a sprinkling of Irish and Dutch as a condiment." He says characteristically "that he has worked on a farm, clerked in a drug-store, taught school, 'toted a grip' on the road, practised medicine and written for the newspapers."

Unlike most self-made men, the doctor does not too idolatrously worship his creator, although it is evident that he is not at all out of conceit with his own handiwork. He declares that "he got what little he knows by reading, writing and thinking. He believes that there is no school like experience, he bankrupts himself daily to gratify his taste for books, pictures and music, and rejoices in his penury. He loves dogs and children and never tires of the beauties of Nature. He could not live in the city if he would and would not if he could."

For the sake, perhaps, of brother physicians who may have literary aspirations, or for the sake of brother littérateurs who may not as yet have attained his success he gives some details of his methods of doing his work. "He thinks that he writes best of the things he knows best and he desires to stay close to them. He has a struggle with himself every time he sits down to write, then works like a galley-slave under the lash and enjoys it." He has a hobby and confesses to it thus: "He is an amateur photographer and wastes his substance in the riotous development of dry plates."

Dr. Naylor's books are pictures of life in a little middle Western town and are said to be drawn from life. He says that his first book was the legitimate child of experience and the details have a foundation in fact. The writing is cleverly done, the characters life-like, the story interesting, its development natural and unforced. In a word the medical profession would seem to have given another to the long list of popular novelists. Worthy elements in his success beyond the mere chance popularity of his books are undoubtedly present and so we may welcome another American literary physician.

OPERATIVE SURGERY IN AMERICA.

This is the title of an article in the October number of the *Nineteenth Century and After*, the well-known English monthly, by Robert Henry Nesbitt, M.D.

Dr. Nesbitt, who has seen the hospitals of England and this country, gives some points for the benefit of what he calls our English cousins. He finds the main distinction between English and American surgical methods to be that there is an evident dependence upon antiseptics in England rather than upon that extreme surgical cleanliness or asepsis which the American surgeon is accustomed to associate with his art. The only other important difference apart from individual peculiarities is the greater use of chloroform in England and the preference for ether in America. Dr. Nesbitt attributes some of our extreme spirit of surgical cleanliness to our environment. In the new tiled and porcelained operating-rooms so common in America it would be hard for any other spirit to prevail. It is a case of action and reaction, a new demonstration that one improvement in any matter always brings another in its train.

In the midst of hints directed to our English medical colleagues, Dr. Nesbitt has included some suggestive material that can scarcely fail to be of interest to the surgeons of every part of the world. We cannot refrain from quoting one valuable passage at some length.

"What I do wish to call attention to, however, is that bruising and tearing of tissue should be reduced to a minimum. Section should be done with a sharp knife—the sharper the knife the less injury—not with the fingers or the handle of the knife. Wounds should not be violently retracted nor stretched to give a better view. 'Pull harder,' is a poor expression for the operating-room. Fasciæ should not be dissected out beyond the limits of absolute necessity. In short, our wounds should remain simple incised wounds and not become contused or lacerated wounds through our own manipulations. During an active hospital service we sometimes see the wounds of one surgeon present those vexatious little delays in healing, such as superficial abscesses or stitch abscesses which irritate both patients and surgeons, while those of his neighbor, not more careful nor cleanly, heal without the slightest disturbance. The secret is that one man pulls and hauls his tissues and does blunt dissection, while the other has acquired the knack of doing his work with no injury beyond that absolutely necessary. The patients of the first surgeon may not die, but we and they expect more than that. Wounds should heal primarily."

EXPERTS.

The *Westminster Review* (London) for October has an article on this subject that is the usual antivivisection howl. It becomes increasingly difficult to understand how intelligent editors of reputable magazines admit this sort of rot to their pages. This is the usual collection of hints, half stated facts, garbled reports and insinuations. Fortunately the article is much shorter than is usually the case. This shows editorial good sense at least. The gist of the present attack on experimental medicine assumes that practically all physicians, absolutely all who are not outspoken in their condemnation of vivisection, are ready to experiment upon human beings and even to make their patients the unconscious subjects of scientific experiences. For people who will believe such statements there is nothing to be said. There is no common standpoint of recognized truth from which argumentation

against their opinions can begin. They must be left to their systematized delusions founded, as they are, on groundless imperative ideas.

PSYCHIATRY: ANCIENT MEDIEVAL AND MODERN.

This is an excellent historical review of the treatment of mental diseases in all times by Frederick Lyman Hills, M.D., of the New Hampshire State Hospital. It appears in the *Popular Science Monthly* for November. There are some striking facts in this history of the popular attitude towards insanity. For instance, the author says that it is probable that one-fourth of the 40,000 persons executed for witchcraft during the first 80 years of the seventeenth century in England alone were insane. While some of the poor insane were taken thus seriously, others were a subject of public exhibition. The famous hospital called Bedlam in London was converted in the reign of Henry VIII. into a house for the reception of lunatics. Up to the year 1770 the patients were exhibited to the public like wild beasts in cages on payment of a penny and they are said to have afforded much sport to the visitors who flocked to see them in numbers estimated at not less than 48,000 annually. Surely not a thought to dwell upon in these latter days.

The spirit that gave rise to the French Revolution and its awful horrors by a queer contrast proved the origin also of a proper realization of the duties owed by the State and the medical profession to the unfortunate insane and also we may add to the deaf and dumb and the blind. It was as a result of the recognition of inalienable individual rights brought about by the declaration of the "Rights of Man" that Pinel was able to obtain permission to remove the chains from the insane patients at Bicêtre and the Salpêtrière. The improvement in the treatment of the insane among English-speaking people is, curiously enough, largely due on both sides of the Atlantic to the initiative of the charitable spirit of that well known philanthropic body, the Society of Friends.

The history of psychiatry is interesting and of suggestive importance, because it represents the gradual development of the attitude of mind which recognizes the diseased state from which insane patients suffer. The progress to gentleness in the treatment of the insane represents the gradual evolution of unselfish philanthropy in the advance of culture. Recent years have seen the development of the open-door system and the almost complete eradication of all methods of restraint. The more wholesome feelings in this matter are an index of advance in true humaneness and a forecast of the still greater spirit of kindliness toward mental unfortunates that is to develop during the present century. History in this becomes a teacher of practical importance, because an incentive to earlier evolution of true popular notions in this great and ever increasing subject.

CORRESPONDENCE.

OUR LONDON LETTER.

[From Our Special Correspondent.]

LONDON, November 16, 1901.

THE GENERAL MEDICAL COUNCIL—ELECTION OF MEMBERS FOR ENGLAND, SCOTLAND AND IRELAND—FAILURE OF DIRECT REPRESENTATION—OPINIONS OF SIR JAMES PAGET—THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE—ILLNESS OF A PROMINENT PATHOLOGIST.

WE have here, as you know, a kind of medical Parliament or Senate, the General Medical Council, which is supposed to look after the education of candidates for admission to our noble profession and the professional morals of its members. In a previous letter I gave a sketch of the composition of this highly respectable, but only moderately useful body. The bulk of it is made up of representatives of our numerous universities, colleges and corporations which grant the license, as Molière puts it, *purgandi, seignandi, taillandi, coupandi et occidendi impune per totam terram,* or, to be accurate, such portion of the earth's surface as is comprised within the sphere of King Edward's sway. In addition to these, there is a handful of members of the Council who are elected directly by the profession. Of these "direct representatives" England has the privilege of possessing three, while Scotland and Ireland have each one. They are elected for five years, and their lease of representative life has now with one exception virtually run out. The exception is Mr. Victor Horsley, who was returned at a by-election four years ago. Mr. Horsley had announced his intention of waiving his right to sitting for another year, and of offering himself for re-election with the others. Almost at the last moment, however, it was discovered that, according to the wording of the Act, if he resigned before having served out his time, he could not stand as a candidate.

The medical profession of Great Britain will, therefore, in another week or two be called upon to take part in a general election in miniature. Owen Glendower boasted that he could call spirits from the vasty deep, but Hotspur unkindly asked if they would come when he called. This may be applied to the profession in regard to the election. Judging from the precedent of the last two or three, they will not come however urgently they are called. The fact is, the medical profession as a whole regards the election and the General Medical Council, its acts and deeds, as well as its alleged misdeeds, with profound indifference. The whole business is practically left to a small body of fussy nonentities who think that the professional world is out of joint and that they were born to put it right. Their aim is not to raise the general standard of scientific knowledge, of intellectual culture, and of personal character and conduct, but to make it a profitable commercial monopoly. Their ideal is a strong trade-union. The election will, therefore, turn

on such matters as the prosecution of quacks, the suppression of certificated midwives, and the "boycotting" of practitioners who make their own terms with friendly societies and similar organizations. The candidates—on the enumeration of whose names I need not waste a line—have been on the stump for some weeks, and the medical journals are full of their dreary oratory. Among the candidates for England is a homeopath, who, like the rest, is calling for the reform of things in general. They all profess to believe that everything could be put right, as by the waving of a magician's wand, if the General Medical Council were "reformed," that is, if it were to be composed entirely of "direct representatives." In order to appreciate the statesmanlike character of this demand, it is necessary to know that, in the judgment of all sane men who have given any attention to the subject and dare to speak out, "direct representation" has been an utter failure from the beginning and now threatens to become a disgrace to the profession. At recent elections men of no professional standing whatever have been returned, who, by their illiterate speech and their narrowness of view characteristic of the petty tradesman, have brought themselves and the constituents who chose them into contempt. The violence of others, for whom the excuse of want of education cannot be pleaded, has disgusted sensible men. Not long ago I heard a man, who may be taken as the type of a British doctor of the best kind, when some one spoke of the increase in the number of direct representatives that is being clamored for, exclaim with a groan, "More of that sort? Heaven preserve us!" This may be taken as representing a widespread feeling, but the incurable apathy of the profession in regard to medical politics prevents the feeling finding practical expression. Scarcely a third of the practitioners of England could be got to vote in the most fiercely-contested election there has yet been—that which took place four years ago when Mr. Horsley defeated Sir Walter Foster.

I have just been reading the "Memoir and Letters of Sir James Paget" by one of his sons which has recently been published. There are in it one or two passages which have a special interest at the present time. Paget was a member of the General Medical Council, and under date October 30th, 1896, we find him complaining to Sir William Turner (who is now its president) that "the whole work of the Council is constantly becoming more political." He goes on to say that "the direct representation will not improve it, but will steadily diminish its influence on the advancement of science and of all forms of useful knowledge." Paget spoke from most extensive experience of men and things in the medical profession; he was also a man of singular intellectual honesty, and his opinion on a matter of this kind is of the greatest possible weight.

Among those whom the King delighted to honor on the occasion of his own birthday was Mr. A. L. Jones, the Liverpool merchant whose name has come so prominently—and so persistently—before the public during the last two or three years in connection with the Liverpool School of Tropical Medicine. It has been a close run between him and Major Ronald Ross; it is doubtful, indeed, which of their names has shone most regularly in the journalistic firmament. Of course, neither of these illustrious men can be suspected of a vulgar desire for advertisement; they shine because they are luminous, and if their light has not been hidden under a bushel, the reason of this is doubtless that otherwise the world would have been left in darkness. The world, however, is proverbially ungrateful, and one hears that Liverpool is getting a little tired of Sir A. L. Jones, Knight Commander of the distinguished order of St. Michael and St. George; and it is even whispered that the medical profession of that city is beginning to feel that it has had almost enough of Major Ronald Ross. They are not so proud as they perhaps ought to be of the School of Tropical Medicine which they owe to the commercial enterprise of Sir A. L. Jones. It has been uncharitably suggested in a weekly journal called the *Critic* that the aforesaid Knight's munificence in fitting up scientific expeditions to the West Coast of Africa is intended to hypnotize the British public into the belief that the happy hunting-grounds which he has made for himself in that ill-favored region are in reality first-class health resorts.

As for the school, if advertisement in season and out of season can make it prosper it should be successful. Probably it does fulfil the object of its existence; at any rate those concerned in the venture profess to be satisfied with its progress. It certainly is excellently equipped and it has teachers of unquestionable ability. The only thing which it lacks is students. I have been told on good authority that last term the number of seekers after knowledge who knocked at its gates was—four. But as the prophetic soul of Sir A. L. Jones, dreaming of things to come, has quite recently induced him to found a college for students which it is said will in time provide accommodation for 200, it is evident that he puts his trust in the future. And the announcement of the fact has also, it may be presumed, its purpose in the present.

Dr. Lazarus-Barlow, one of the rising lights of pathology in this country, has been sick nigh unto death from the effects of a postmortem wound. It is said that he has had to undergo amputation of the arm. He is now slowly recovering.

INSURANCE EXAMINATION FEES.

To the Editor of the MEDICAL NEWS:

DEAR SIR: I was much interested in the editorial in your issue of November 2d on contract services. As it is in direct line with another great evil, I beg to say a word about it.

The various fraternal insurance societies ask an examination equal to that of old line companies

even to the urinalysis, and have the boldness to ask it all for the munificent sum of one dollar. And this does not include it all. We are further asked to do an agent's work by filling out the applications for membership and even urged to solicit new members.

The old line companies have set the price of these examinations at from $3.00 to $5.00, which is reasonable and fair—certainly not too much—and do not ask the doctors to do any extra work at all. They are willing to pay a fair price for good work and their medical directors are not beggars, but when I see a member of our noble profession asking his brother to work for one-third to one-fifth of what the work is worth I am shocked and ashamed.

What about the doctors who will make these examinations for "contract price"? They are only establishing a price for the rest of their work, and when the demand for the reduction is made they will probably be so afraid their next-door neighbor will get the case that they will readily cut the price in a similar manner to the insurance fee.

I would suggest that every medical society in the land take up this matter and do away with the absurdity of working for one-third to one-fifth price, and would add that, in my humble opinion, no self-respecting doctor will do $5.00 worth of work for $1.00 when it is for people able to pay.

I am free to reduce a charge for charity or even make no charge at all, but when it comes to reducing prices in order that this or that society may advertise the very low cost of insurance in order to compete with others, I protest.

In regard to fraternal insurance, I might also say that it is much the same as other things. People who try to get something for nothing usually get left, and the 2,000 defunct societies in our land will illustrate this fact.

CALCIFIED EPITHELIOMA—HEMO- AND CYTODIAGNOSIS IN SURGERY—RACHICOCAINIZATION—CHLOROFORM ANESTHESIA—ETHYL CHLORIDE ANESTHESIA—ANTITETANIC SERUM—CRANIAL TRAUMA WITH SURGICAL INTERVENTION—EPILEPSY WITH SURGICAL TREATMENT.

J. Reverdin (Geneva) at the Fortieth French Congress of Surgery, held at Paris, October 21 to 26, 1901, read the notes of a case of calcified epithelioma. The tumor was removed from the neck two years ago, was of bony hardness, and in gross appearance strongly suggested the variety described by Malherbe of Nantes. Contrary, however, to the teachings of this authority and his pupils a recurrence took place. It would, however, appear that the essential benignity of the calcareous epithelioma is less definite than they have supposed. Malherbe himself reported to Reverdin the fact of one recurrence. The author has correlated some fifty-three cases of this disease and found only two examples of recurrence, namely, the cases of Malherbe and himself. The author's patient refused a second operation, but was followed for some time. After a while the tumor grew to considerable proportions.

Tuffier (Paris) presented a discussion of the comparative value of hemo- and cytodiagnosis in surgery, claiming that they furnish the means of deciding between two classes of affection, the suppurative and the non-suppurative. One example, which he quoted, was the case of a woman, pronounced by a number of competent physicians to be the subject of an osteosarcoma, who was found to have a suppurative condition by an examination of her blood. This diagnosis was confirmed at the time of the operation. Again, the decision between a case of appendicitis and of typhoid fever can often be fixed to a degree of nicety by this method alone. Finally, the distinction between the various types of tumors can also be made out thoroughly. The cytodiagnosis conceived by M. Widal is equally a means of settling difficult points. Lumbar puncture will permit us to distinguish definitely between a fracture of the skull and simple cerebral contusion, provided blood is found in the cephalo-rachidian fluid.

Villar contributed a report of seventy-six rachicocainizations for various surgical operations, chiefly on the lower extremities and the subumbilical zone of the trunk. His first series comprised thirty-six cases, of which two only were failures and each of these was a laparotomy. No bad effects were noted in the other cases, beyond a cephalalgia of great intensity which seemed to be the only actual sequel of the injection. Three of these patients died, the first from shock due to acute intestinal obstruction; the second from the after-effects of a complicated fracture of the pelvis, and the third was hopeless at the time of the operation. In the second series, namely, forty cases, there were no deaths and no unfavorable sequelæ.

Peravie (Paris) narrated his experiences with chloroform as a general anesthetic in 2,000 cases. He had only one death which occurred at the end of the operation and made him believe that after all the anesthetic had little or nothing to do with it, because fatalities from chloroform alone usually occur very early in the course of the operation. The method of administration which he used is the small dose continuously given. The author said that every practitioner should keep notes of all his cases of general anesthesia and report the same, especially with the view of making comparisons with the injection of cocaine into the spinal cord.

A. Malherbe (Paris) commended a new method of giving ethyl chloride for general anesthesia during operations which last a short time. The procedure involves pouring from a half to a full teaspoonful of the drug into a tight cone, shutting off the air and compelling thus the in-

spiration of concentrated vapor. Full anesthesia supervenes in a very few seconds. If, however, the operation is to be prolonged, it is better to change off to chloroform so soon as the fact of long duration becomes evident.

LETOUX (Vannes) delivered a dissertation on the therapeutic value of antitetanic serum, basing his observations upon four recent cases, comprising three among farmers with wounds of the foot and one in a cook. In all the injury and infection were of comparatively recent date, ranging from seven to ten days. The treatment was begun as soon as the earliest symptoms of tetany showed themselves. It is not always necessary to resort to anesthesia and after all the injection of the fluid into the cerebral ventricles is not a difficult procedure. In the opinion of this observer, his prompt and complete cures were due to the generous injections he used. Ten cubic centimeters were thrown into each hemisphere.

BOUSQUET (Clermon-Ferrand) narrated six cases of injury to the cranium which required surgical intervention. In all those operated upon five days after the accident or earlier the results were ideal. Symptoms of cerebral compression soon appeared in all of the cases and the craniectomy permitted access to and removal of the cause of the difficulty. He also referred to another series of cases in which the operation was done too late. It is more and more evident that these cranial operations must be done at the earliest possible moment after the appearance of any symptoms, because delay often results in permanent or hopeless damage by the factors which cause the symptoms.

VIDAL (Périgneux) stated that by means of amyl nitrite he had been able to distinguish cerebral compression as the cause of a general epilepsy. Hemicraniectomy revealed a small, sessile, intradural fibroma. This was at once removed and a cure followed. The operation was done several months ago and since that time no vestige of the epilepsy has remained.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON PEDIATRICS.

Stated Meeting, Held November 14, 1901.

William L. Stowell, M.D., Chairman.

Automatic Siphon.—Dr. Henry L. Coit said that one of the principal difficulties in arranging for infant-feeding with the proper proportion of ingredients in the prepared food is the difficulty of easily obtaining cream of a definite percentage of fat content. He thinks that the siphon he presented will overcome this difficulty. It is a creaming siphon that will effect the complete separation of the cream at the cream line, or deliver a mixture of cream and skim milk, at any line to be determined upon. The ordinary quart milk-bottle is used as the source of the cream and milk. This is supposed to hold 32 ounces, but most of them do not hold much more than 31 ounces. There are differences in the contents, because the bottles are molded and some of them contain more glass than others. This gives rise to some inaccuracy in the delivery of a definite quantity of milk and cream, but not enough to vitiate the proportion seriously. The table on which the bottle rests must be level and the siphon must be inserted to the bottom of the bottle. The end of the siphon that dips into the bottle is funnel-shaped. This enables it to be filled easily with water, and this lessens the danger of the nursemaid applying her mouth to the end of the siphon in order to start the flow of liquid, which is always an objectionable proceeding. Moreover, the presence of the funnel makes it easier to clean the tube in running water, and when inserted into the bottle the funnel-shaped end causes the instrument to rest more evenly on the bottom of the bottle than would otherwise be the case. If about four ounces are allowed to remain in the milk bottle, with the usual milk, this will contain about 20 per cent of fat. When six ounces are left it contains about fifteen per cent; eight ounces, about twelve per cent; 11 ounces about 10 per cent, and 16 ounces about 8 per cent of fat. The ordinary milk as served to customers in cities is presumed to contain, according to well-known investigation, about 4 per cent of fat.

Top Milk.—Dr. Chapin has found that the best way to obtain a fairly constant cream is to allow milk to stand for about six hours in a cool place. The creamy layer, known as gravity cream in the trade, contains nine-tenths of the butter fat in the milk. If the first nine ounces of this are used, it may be considered to contain cream in the proportion of three to one to the amount of milk. If the first fifteen ounces are used, the proportion is about two to one. For the obtaining of this upper layer Dr. Chapin considers that the dipper, which he suggested some time ago, is cheap and clean and easy of employment. It is a simple matter to give the nursemaid the proper directions for its use. Above all things to be successful, the feeding of infants must be simple. If there is any dirt in milk it is well known that it sinks to the bottom and can often be seen in bluish black particles through the glass of the bottle. By the use of Dr. Coit's siphon, this dirt is not apt to be removed, or at least not removed entirely, because the upward flow through the siphon is gentle and does not disturb the lower layer of milk very much. The dirt remains to contaminate the upper layer of of milk, which is left in the bottle after siphoning to be used for feeding purposes.

Safety-Pin in Vagina.—Dr. Sara Welt-Kakels presented a safety-pin that had been removed from the vagina of a child of eight years of age. When the child first came under treatment it was suffering from a vaginal discharge that was at times bloody. This led the mother to think that perhaps the child was developing precocious menstruation. The discharge was considered an ordinary leucorrhea, and was treated by vaginal

irrigation with permanganate of potash solution and improved considerably. After a time, however, the discharge recurred and once more was streaked with blood. A small vaginal speculum was then inserted and grated upon a hard object. The safety-pin was found and removed. It was considerably corroded by the action of the vaginal secretions. Since its removal the discharge has not reappeared.

Coin in the Esophagus.—A child of thirteen months was brought to the speaker suffering from severe vomiting the origin of which was traced apparently to its having swallowed a penny. The child was given the coin to play with and it disappeared; afterward whenever food was taken vomiting occurred. The first physician who saw the case recommended the potato cure, but the potatoes were vomited. An operation was then suggested, but the mother refused to permit it. Dr. Kakels located the cent by means of the Roentgen-ray and found that it was situated in the esophagus about the level of the first rib. It was removed by means of a flexible bougie with the coin-catching attachment. There has been no vomiting since and the patient's general condition has improved very much.

Apparatus for Collection of Urine and Feces.—Dr. Kakels presented an apparatus that is used in Prof. Heubner's clinic for the collection of urine and faces for the purposes of observation upon child metabolism. A tube is fitted to the urinary apparatus in front and to the anus behind and the child is placed in a garment that enables these tubes to be readily held in position. Professor Heubner says that children do not stand being in the apparatus for long periods, but if a physician has occasion to collect urine, for instance, and wishes to obtain it in some less inaccurate way than is usually the case, this apparatus is extremely useful.

Widal in Typhoid in Children.—Dr. Milton A. Gershel read a paper on the value of the Widal reaction in children as illustrated by cases seen in the service of Dr. Koplik at Mt. Sinai Hospital. Typhoid in children in the hospital experience runs an atypical and often an anomalous course. The temperature curve is not infrequently irregular, the spleen is often not enlarged, and, besides, enlargement of the spleen is not as significant in children as in adults, because it occurs whenever rachitis exists or in intestinal disturbances generally. The method of applying the Widal test at Mt. Sinai Hospital was to determine whether agglutination of the bacilli took place when the blood was diluted to the extent of one to twenty. If there were still doubts, then the test was repeated with a dilution of one to fifty. Dried blood was used in all cases, except where the clinical course of the case aroused serious suspicious of typhoid and yet the Widal test continued to be negative. In somewhat less than half the cases typhoid fever in children ran the usual course. In the remainder it was suspected that other diseases were present. Among these were such conditions as tuberculous meningitis, or peritonitis, certain cases of pneumonia, and some seemingly simple intestinal conditions. In only 36 of over 100 cases was the Widal reaction positive at a first examination. Thirteen per cent of the cases gave the reaction before the seventh day of the fever, 46 per cent before the fifteenth day and 85 per cent before the twenty-fifth day. In more than half the cases, therefore, the Widal reaction left the diagnosis in doubt until well on in the third week.

Late Widal Reaction.—Dr. Lovett Morse of Boston, in the large series of cases collected by him, found that the Widal reaction did not occur in most cases before the end of the second week. Professor Musser pointed out in the Philadelphia series of cases that the reaction did not as a rule occur before the seventh day. In this series of cases at Mt. Sinai Hospital, eleven gave a positive Widal before the seventh day. Because the occurrence of the Widal reaction is delayed there is no reason for thinking that the disease is not typhoid if other symptoms raise the suspicion of its existence. In one case thirteen blood-examinations were negative before the positive reaction was finally obtained, yet all the time the case was running a typical typhoid course. Other symptoms, such as the diazo-reaction and even bleeding from the bowels, had occurred. In some cases the Widal reaction is only positive during convalescence from typhoid fever. In most cases the occurrence of a negative reaction has but very little significance. The experience at the Mt. Sinai Hospital points out that typhoid fever often exists in children in cases where it was usually unsuspected and where the symptoms apparently pointed to the existence of some other disease. In all cases presenting bronchial or meningitis symptoms that occur during the summer and fall the Widal reaction should be looked for. It often clears up the diagnosis of the case and shows the typhoid origin of the symptoms.

Exanthematous Typhoid.—In one case at Mt. Sinai Hospital the patient, after having been admitted with a rather high fever, developed an extensive exanthematous eruption. This aroused the suspicion of scarlet fever and the case was isolated. An examination of the blood showed that the Widal reaction was present. Later the disease ran a typical typhoid course. Dr. Koplik considered this to be one of the rare cases of exanthematous typhoid that have been reported by certain authorities, the existence of which has sometimes been doubted. In one case the patient seemed to be suffering from lobar pneumonia. Under ordinary circumstances a few years ago no other diagnosis could have been made. A typical Widal reaction was present and the subsequent history showed that the case was undoubtedly one of typhoid. Three other children in the family suffered from typhoid fever, displaying the ordinary symptoms of typhoid and the Widal reaction and cases developed in

the same house, on the floor above and below that on which the child had lived. In one of the cases at the Mt. Sinai Hospital all the symptoms of purulent meningitis were present. The child had the stiffness of the neck muscles, was stupid and not easily aroused and had the Koenig symptom. The Widal test was made and a positive reaction obtained. Afterward a needle was inserted into the spinal canal and some cerebrospinal fluid removed. This proved to be clear, but contained typhoid bacilli, thus confirming the Widal test. The child recovered, showing that the diagnosis of purulent meningitis would have been a mistake.

Importance of Widal Reaction.—Dr. Koplik said in the discussion that the employment of the Widal reaction at the Mt. Sinai Hospital has made it very clear that it is extremely important to make the Widal test whenever children suffer from febrile symptoms for which no sure cause can be given. There are many conditions in children which resemble each other and the diagnosis can frequently only be made by exclusion. It used to be said that typhoid was rare in children. This was only because of the difficulty of making an assured diagnosis of the disease. He has seen the Widal reaction positive in a child so well that it was playing around the ward, though with a slight febrile temperature. The case did not prove a severe one, but it can be easily understood that in the midst of a large family or in a crowded tenement-house such a case might easily prove a center for the spread of infection. In meningeal cases, especially, it is important to make the Widal test, since one does not always care to make a lumbar puncture, and, moreover, the diagnostic significance of the cerebrospinal fluid is not always final.

Frequency of Typhoid in Children.—Dr. Berg of New York said that it is not ten years since a great specialist in children's diseases said in New York that he doubted if typhoid fever ever occurred in children under five years of age. Now we know, mainly as the result of the Widal test, that the disease is not uncommon even in very young children. If they are exposed to infection they are quite as liable to take the disease as adults. Undoubtedly the Widal test is of extreme importance for the diagnosis of typhoid. It is the most omnipresent symptom. Dr. Cabot of Boston has collected five thousand cases of typhoid fever in 97 per cent. of which the Widal test was positive. The Widal reaction is not of importance for the early diagnosis of typhoid fever. For this purpose the blood-count is undoubtedly better. There will often be found a diminished number of white blood-cells on the first or second day in bed with typhoid fever. The demonstration of the lowered leucocyte-count is rather easy and if taken in connection with other clinical symptoms may be of very great importance in pointing out the existence of typhoid fever in a doubtful case long before the Widal reaction develops.

Bovine and Human Tuberculosis.—Dr. David Bovaird of New York read a paper on primary intestinal tuberculosis in human beings and its relation to bovine tuberculosis. The recent paper of Professor Koch before the International Tuberculosis Congress has made interest in this subject acute. Dr. Bovaird has been collecting data on the subject for some years. The number of cases of primary tuberculosis of the intestines supposed to be connected with bovine tuberculosis directly are extremely rare. Bacteriologists are not agreed whether human and bovine tubercle bacilli are varieties of the same microorganism or are individual bacteria with certain extrinsic similarities. Tuberculosis in cattle is not at all rare. It is, however, not as frequent in this country as has been sometimes asserted. Professor Osler points out that in Baltimore about three per cent of the more than 5,000 cattle that are slaughtered yearly are tuberculous. In Boston less than 1 per cent are found to be affected with tuberculosis. The German Government called attention to the fact that bovine tuberculosis was not liable to be communicated to human beings by eating the flesh of tuberculous animals, unless nodules of tuberculous infiltration occurred in the muscles. This is, however, extremely rare. With regard to the milk of tuberculous animals, it is dangerous only when the udder of the animal is affected and tubercle bacilli thus find an entrance in numbers into the milk. Adami, however, has found tubercle bacilli in milk where there was no demonstrable tuberculous affection of the udder to be found after very careful examination by all the known physical methods.

Milk Dangers.—Professor Nocard of Paris pointed out that even when the milk of animals injected into the peritoneum of guinea-pigs proved to contain virulent tubercle bacilli and set up tuberculous processes, the fluid might still be perfectly harmless when ingested by the mouth. The digestive juices bring about changes in the vitality of the tubercle bacilli, or absolutely deprive them of life, and so prevent their inflicting any injury. It is evident from the experience of many parts of the world that milk is virulent only when there are very many tubercle bacilli in it and when this material is used almost exclusively as an article of diet as is the case in infants and in invalids.

Bovine Tuberculosis in England.—English cattle seem to suffer more from tuberculosis, and tubercle bacilli are oftener found in the milk supplied in English towns than in our country. Kanthack found that more than one-half of the cattle near Cambridge in England were affected by tuberculosis. In Liverpool it was noted that the milk from cows taken care of in the city itself was less dangerous in this respect than that obtained from the country. The reason for this was that more care as to cleanliness and the maintenance of health was insisted on in the city then in the country. There is no doubt that under ordinary circumstances the dilution of the milk of tubercular animals by that from healthy animals greatly lessens the danger from this source.

Milk and Human Tuberculosis.—There is but scanty evidence of milk producing tuberculosis in children. Notwithstanding all that has been said in this matter and the amount of sensational claims made, Dr. Bovaird after careful search of the literature has been able to find only sixteen cases in which tuberculous infection could be fairly traced to milk. This is an astonishingly small number, yet even these few cases show the possibility for this form of infection and point out an ever-present danger. Tuberculous processes often exist at the same time in the respiratory and intestinal tracts. It is probable that at times the tubercle bacilli penetrate the intestine without producing injury, that is, without ulcerative lesions, but then they are caught in the intestinal lymph-nodes. It is only when intestinal lesions exist exclusively or when the abdominal lesions are much more pronounced than the respiratory lesions that tuberculosis can be considered to have found its entrance through the intestines. Professor Woodhead of England considers that primary intestinal tuberculosis is rather frequent. Nearly all the continental authorities on the subject of tuberculosis are opposed to this opinon.

English and American Statistics.—While in England the proportion of intestinal primary tuberculosis to all other forms of tuberculosis seems to be as high as eighteen per cent, in New York in three series of cases it is scarcely more than one per cent. This makes a difference of opinion that is extremely hard to reconcile with facts and a problem whose solution Dr. Bovaird is unable to reach. At the New York Foundling Asylum there are nearly 2,000 infants under the care of the institution. In case of death autopsies are made and in two series of cases of tuberculosis, 125 in all, only five cases, three in the first series and two in the last one, could be fairly considered to be primary intestinal tuberculosis. In this series of autopsies the deaths from tuberculosis represent eleven per cent of all the causes of death. This is considerably lower than that of foreign observers, but is very nearly the average percentage of deaths from tuberculosis according to various observers in this country. Tuberculosis of the intestine is less frequently observed there than abroad, and it is evident that tuberculosis is seldom due to tubercle bacilli in milk. It would seem, however, that the possibility of infection in this way cannot be denied.

Respiratory and Intestinal Tuberculosis.—Dr. William H. Park said that wherever patients with respiratory tuberculosis are found a great many tubercle bacilli are sure to be present in the air. It is possible, then, even when the primary lesions of tuberculosis occur in the intestinal tract that the source of these micro-organisms may have been the air from which the microbes are deposited in the mouth and then swallowed. In such cases the true source of the infection is human and is not derived from cows or other animals.

Experimental Work on Tuberculosis.—Dr. Park has recently had made a series of observations on calves at the laboratories of the New York Board of Health. Five animals were inoculated subcutaneously and fed with human tubercle bacilli. Before the experiment none of them showed any reaction to tuberculin. Neither did a sixth animal that was kept as a control. After five weeks of repeated inoculations and feeding with tubercle bacilli, the five animals showed a reaction to tuberculin. Two of them were killed, but no bacilli were found, nor any characteristic lesions of tuberculosis. Two of the remaining three animals have run down in health and are showing signs of some constitutional disease. They will be killed when it is hoped that satisfactory lesions have been formed. Some time ago Dr. Ravenel showed by a series of experiments that animals could not be infected with pure human tubercle bacilli. If, however, secondary infective processes were at work as well as tuberculosis, then human tuberculous material became virulent for animals. Human sputum for instance that showed signs of mixed infection produced tuberculous lesions in cattle. It would seem that the presence of other bacilli in addition to the tubercle bacilli lowered the tissue resistance of the animal and caused infection.

Foreign and American Tuberculosis.—Dr. T. S. Southworth said that in a series of autopsies made by him and previously reported he found that the average mortality from tuberculosis in children in this country constitutes from ten to eleven per cent of the deaths from all causes. He is not surprised that foreign statistics should show a much higher proportion of mortality from tuberculosis than our American statistics, for they take much less care of their milk supply. This is especially true in Vienna, where the death-rate from tuberculosis is very high and where the climate seems to have a special effect in creating a tendency to tuberculous infection. Dr. Southworth thinks that there is an evident connection between a high mortality in children from tuberculosis and lack of care in the collection of milk.

Infrequency of Intestinal Tuberculosis.—In closing the discussion Dr. Bovaird said that it is extremely difficult as a rule to decide whether there is primary infection of the intestines or of the respiratory tract. If there are breaking-down tuberculous lesions in the lungs there will always be minute ulcers of the intestines and enlargement of the mesentery glands, but it is evident that in such cases the patients have infected themselves and that their infection has not come from the food. If such cases are carefully excluded from the statistics it will be found that primary intestinal and mesenteric tuberculosis very rarely occurs.

West End Medical Society.—This Society meets next Saturday at residence of Dr. Fielding Taylor. Dr. Jelliffe will read a paper on "Some Phases of the Opium Habit."

VOL. LXXIX. NEW YORK, SATURDAY, DECEMBER 7, 1901. NO. 23.

ORIGINAL ARTICLES.

A CASE OF SUTURE OF A STAB-WOUND OF THE HEART, WITH REMARKS ON, AND A TABLE OF, CASES PREVIOUSLY REPORTED.

BY GEORGE TULLY VAUGHAN, M.D.,
OF WASHINGTON, D. C.;
SURGEON U. S. MARINE-HOSPITAL SERVICE; MAJOR AND BRIGADE SURGEON U. S. V. DURING WAR WITH SPAIN; PROFESSOR OF SURGERY, GEORGETOWN UNIVERSITY.

C. W.; aged twenty-three years, male, negro, was stabbed in the evening of October 2, 1901. On examination about half or three-quarters of an hour later the patient was unconscious, but extremely restless, tossing about and talking incoherently. The extremities were cold and no pulse was perceptible in the radials. A clean-cut wound was seen in the chest, 5 cm. long, extending downward and slightly outward and completely dividing the left fifth costal cartilage close to the sternum. The wound gaped so that the pericardium could be seen.

Preparation was made for immediate operation. The chest-wall was hurriedly washed off with a solution of bichloride and enough ether was given to quiet the patient's struggles. The external wound was extended longitudinally above and below, making the total length 15 cm., the outer flap was dissected back exposing the ribs, the costal cartilage of the fourth rib was divided and the fourth and fifth ribs were divided with bone forceps about 7 cm. from the sternum. The muscles of the fifth intercostal space were then divided and the flap of the chest-wall turned up, clearly exposing the pericardium and left pleural cavity. An opening about 5 cm. in length was seen in the pericardium and was enlarged below to 7½ cm., revealing an opening in the wall of the left ventricle close to the inter-ventricular septum, from which the blood spurted with each contraction of the heart. The edges were quickly pressed together and held so by a pair of hemostats grasping each edge until the wound was closed by a continuous suture of silk in a curved needle, making seven stitches which did not include the endocardium. The wound in the heart was 2½ cm. long and shaped like the letter "Y" with the right branch about half the length of the left. The pericardium and pleural cavities were then emptied of blood and clots, of which there must have been at least 2,000 c.c., and the pericardium closed with continuous silk sutures. About this time the heart stopped and neither artificial respiration nor squeezing the heart was able to start it again. The operation lasted less than fifteen minutes. Death was caused by hemorrhage. There was not time to inject salt solution into the veins, though this was intended, as the most important indication was to stop the hemorrhage and all efforts were devoted to that end.

To the cases reported in the excellent article by L. L. Hill, "Wounds of the Heart, a Report of Seventeen Cases of Heart Suture."[1] I have added my case and 8 others and have arranged them in tabular form, giving, as far as the information could be obtained from the reports, the name of the operator, year of the operation or report, the situation of the external wound, the chamber of the heart wounded, size of wound in the heart, time of operation after injury, whether anesthesia was used, result, and remarks.

A study of these 26 cases sutured gives the following results: Recoveries, 9; deaths, 17; mortality, 65.38 per cent. Of the chambers wounded, the left auricle, 1; left ventricle, 12; right ventricle, 8; not given, 5.

From this it would seem that the ventricles are far more likely to be wounded than the auricles, in the proportion of at least 75 per cent., and that the left ventricle is most frequently wounded of all the chambers. Of those who recovered 2 were wounded in the right ventricle and 7 in the left ventricle (including the apex), 2 possibly non-penetrating and 1 in the apex certainly non-penetrating.

Mortality.—If we subtract from the recoveries the 3 cases in one of which the cavity was certainly not opened and the other 2 in which the cavity was probably not opened—if so, the opening must have been very small—we find the mortality of *penetrating wounds* of the heart as shown by this table to be 76.93 per cent.

Time of Operation after Injury in Relation to Prognosis.—If we study the time which elapsed after the receipt of the wound before the operation we will be struck with the difference in the fatal and non-fatal cases; thus in the former the minimum time was "immediately" and the maximum one and one-half hours, time not given in 10 cases, while of recoveries the minimum time was five hours and the maximum over twenty-four hours—time not given in 3 cases. The obvious inference is that if the patient lives after receiving the wound five hours or longer before the operation, his chances of recovery are much better than many operated sooner, as the fact of living five hours without operation proves the wound to be less than the average in severity.

Dangers.—Without doubt the greatest immediate danger is from hemorrhage, next from shock and entrance of air into the heart. Then comes the danger from pericarditis, empyema and pneumonia. Of the 26 cases, 1 had pericarditis; 2 empyema; 2 empyema and pericardi-

19. Bufnoir. 1899	6th left intercostal space.	R. V. Gunshot. .22-calibre.	.....	.....	D. Necropsy showed perforation of ventricle and the anterior opening only had been sutured.
20. Pagenstecher. 1899	4th left intercostal space beneath the nipple.	L. V. Near apex; 2 stitches.	16 hours.	None.	R.
21. Nanu. 1900	3d intercostal space, 4 c.m. from edge of sternum.	R. V. 2 c.m. long. 2 interrupted sutures.	.....	.....	D. on 5th day from infection of pericardium and pleura.
22. Maselli. 1900	Below and internal to left nipple, cutting 6th rib.	L. V. Near apex. 2 stitches.	1½ hours.	.....	D. in 12 hours.
23. Fontan. 1990	Six wounds with scissors between 3d and 7th ribs in cardiac region.	L. V, 12 m.m. long. Continuous catgut sutures. 3 stitches.	6 hours.	Chloroform.	R.
24. Nietert. 1901	.....	R. V. penetrated; 3 silk sutures.	.....	.....	D. after 36 hours.
25. Vaughan. 1901	5th left costal cartilage divided.	L. V. 2½ c.m. long. Continuous silk sutures. 7 stitches.	¾ hour.	Ether.	D. on table from hemorrhage about completion of operation.
26. Nietert. 1901	Left of sternum.	L. V. Not sure cavity was penetrated; 2 sutures.	.....	.....	R.

tis; 1 empyema and abscess of right lung, and 1 bronchopneumonia—7 cases with infection, all of which were fatal except the 2 cases of empyema only.

The urgency of the symptoms and the necessity for prompt and rapid action often prevent the observance of proper aseptic precautions—a fact which probably accounts for the frequency of infection.

Conclusions.—A review of these cases justifies the following conclusions:

1. The time has arrived when a wound of the heart should be operated on with as little hesitation as a wound of the brain, with the expectation under corresponding conditions of getting equally good results. The mortality must inevitably be high—not from the operation but from the injury—especially if all cases including desperate ones be undertaken. Selection of cases who have survived five or more hours after receiving the wound would give a good percentage of recoveries, but such selection is not to be recommended.

2. In all cases of wounds in the region of the heart, with symptoms threatening life, an exploratory operation should be done by making an osteoplastic flap by dividing the fourth and fifth costal cartilages at their attachments to the sternum and the ribs about one inch external to their attachment to the cartilage, somewhat according to the method of Roberts. This flap turned up as a door on a hinge gives a good view of the pericardium and can easily be enlarged upward if more room is required.

3. While early and speedy operation is often essential to success, yet the importance of asepsis cannot be too strongly emphasized on account of the great danger of pericarditis and empyema. If there has been much hemorrhage a quantity of physiological salt solution, approximately equal in amount to the blood lost, should be injected into a vein while the surgeon is operating on the heart, if it has not been done sooner.

WHEN AND HOW TO INTRODUCE THE STOMACH-TUBE.

BY MARK I. KNAPP, M.D.,

OF NEW YORK;

ATTENDING PHYSICIAN, EAST SIDE DISPENSARY; DEPARTMENT OF DISEASES OF THE STOMACH.

IN affections of the stomach the obtaining and examining of the contents of the stomach is the *sine qua non.* No matter how large our experience is, the microscopical and chemical examination of the stomach-contents is absolutely necessary for a correct diagnosis and a negative result of our efforts is as valuable as a positive one. And let me say here, in parenthesis, anticipating my reports on the subject, that the microscopical examination of the test-meal is at least just as important as the chemical one, if not superseding it. We may well understand the condition of the consulting patient and probably our errors as to quality may diminish with our experience, yet quantity cannot be imagined. To be clearer, we may well and correctly adjudge all symptoms complained of as ascribable to a condition of hypochlorhydria, yet how far this condition has gone cannot be estimated; therefore to satisfy both patients and ourselves, a quantitative analysis must be made.

Recognizing the necessity for examining the stomach-contents, the question arises, Are there any objections and contra-indications to the use of the tube, and, further, how are we to introduce it? Objections and contra-indications to the use of the stomach-tube are given in the text-books, almost anything being considered a check—diseases of the heart, diseases of the lungs, diseases of the aorta, general diseases, pregnancy, etc. Why? This is not explained. Why should a soft-rubber tube not be allowed to pass the esophagus, while a bit of bread, with its ragged and pointed ends, is granted this precious privilege?

Objections to its entering the gullet might be raised on three points: (1) because of its producing pressure; (2) because of its diameter, and (3) because of possible injury to the soft parts. Can any one imagine a soft, readily-yielding rubber tube being guilty of such a heinous crime? Do we not know from our successful experience with the soft-rubber tube in other parts of the body that the very reason for using soft-rubber tubing is that it has been convincingly demonstrating itself inoffensive and incapable of causing physical injury? The very reason for using soft-rubber tubing is because it readily and meekly adapts itself to its surroundings, flattening itself whenever other progress is impossible, taking—possibly involuntarily—the only course open to it, twisting and turning whenever demed wise to reach its destination and stops short only when further progress is absolutely barred—qualifications and virtues that many of us might emulate with profit.

It seems to me, after quite a large experience, that when there are no strictures anywhere between the mouth and past the cardia there are no objections or contra-indications to the introducing of the soft-rubber stomach-tube; in order to determine the existence of a stricture the invasion of the esophagus is absolutely essential. Ulcus œsophagi, a disease which, by the way, exists quite frequently, might contra-indicate the introduction of the tube, but not because the tube might penetrate, but because of its gliding over the raw and highly-sensitive spot. All objections and contra-indications stated, except those just now mentioned, are theoretical. The vitality of the patient can in no way suffer if the tube is introduced skilfully and by means of the stomach-tube director invented by myself, rapidity and safety, even by a novice can easily be acquired. I have introduced the stomach-tube with decided benefit

even in the last stages of tuberculosis, nay, even in the much-dreaded ulcer of the stomach and in advanced heart disease. Boas reports (cited by Hemmeter) having introduced the tube with success in cases of pregnancy, typhoid fever, and aortic regurgitation, with favorable results. Why should a soft-rubber tube be harmful? It certainly cannot cut nor cause any abrasions and if not introduced into the larynx, a feat sometimes accomplished, the tube, if not hard—and this it should never be—will readily yield to any pressure that any nearby tumor, aneurism not excepted, might cause. There are some men who, do what they may, cannot introduce the tube. But such men, unskilful in the handling of the tube although otherwise very creditable to our profession, should simply abstain from this practice, unless with the aid of my director. As a general rule, I might state that so long as the patient can swallow hard substances, such as meat and bread, without inconvenience there exists no contraindication to the introduction of the tube.

The stomach-tube must be of soft rubber. If the regulation stomach-tube is not at hand any soft-rubber tubing of proper diameter and length may be used. One can make his own stomach-tube from ordinary soft-rubber tubing by cutting off the desired length, cutting the holes that he desires, smoothening the holes thus cut out with a red hot glass rod and washing off the sticky rubber with chloroform. The old-fashioned hard tube, with all its actual terrors, is or should be a thing of the past. The use of any directing rod within the lumen of the tube must be condemned even if advocated by such men as Penzoldt. Even the introduction of the sound should invariably be preceded by the introduction of the soft tube.

The next question is how to reach the stomach. Before introducing the tube a few minor details have to be taken into consideration. The diameter of the tube may vary from the size of an ordinary catheter to about ⅜ of an inch. I usually use two sizes in the same patient when seen for the first time—a small one giving less of the choking sensation first, when going into the fasting stomach—in order to accustom the patient to it—and a larger tube when aspirating the test-meal. By this diplomatic move the patient is somewhat at ease when the test-meal is to be aspirated; as a mater of fact the full stomach cannot bear the tube with the same degree of tolerance as the fasting stomach. The length of the tube should be about 28 inches, from 20 to 22 inches being the length between the incisor teeth and the cardia, according to the stature of the patient. A ptotic stomach will naturally require a longer tube. I like the method in which the proximal end of the tube is connected by a piece of glass tubing to another piece of soft rubber tubing. This glass rod permits us to see the quality and nature of the aspirated matter before it goes into the pear-shaped rubber bulb, a fact which will be well appreciated by the physician, as very often blood is seen through the glass tube, a signal that the tube should be instantly withdrawn. This appearance of blood need cause no alarm nor apprehension, as it is caused in most instances, by the patient straining; yet on seeing it we should be admonished to withdraw the tube. The other points to be considered are not to soil the patient nor soil ourselves. For that reason the patient's clothing is protected by tucking a sufficiently broad towel behind the shirt or waist collar and if the patient is a woman turn up the skirt of her dress. Anything savoring of or suggesting surgery should be sedulously avoided; for that reason I do not like the rubber apron on the patient or Turk's rubber pocket underneath the chin. The physician may protect himself by wearing a white gown, but one very soon learns to dispense also with that if the tube be introduced in the manner I am about to describe.

The patient is seated in an ordinary chair—specially constructed chairs are not required—and before attempting to introduce the tube the patient is told what is wanted. We demonstrate to the patient the absolute impossibility of doing any harm, trying to convince him that a soft tube could not possibly hurt. We likewise must urge the patient to keep on breathing, for, as a rule, he momentarily suspends respiration and the consequence is that he becomes cyanotic—a thing which is liable to embarrass and frighten the inexperienced physician. The choking sensation which the patient feels must be explained on the ground that it is something unusual and he must be told that he will soon be able to introduce the tube himself. We must likewise warn the patient not to bite on the tube as it would prolong the procedure, although closing the lips is of advantage in introducing the tube. False teeth must be removed. The patient is given a pus basin or something similar and is told to hold this with both hands under the chin. This has a double purpose. It catches saliva or vomit and busies the hands of the patient, who otherwise is very apt to reach for the tube.

The patient is now ready. The physician stands at the right side, putting his left arm around the back of the patient's neck. In this way we accomplish two very important things. First, our arm gives the patient an agreeable support to his back and, secondly, with our arm around the back of his neck we have the most robust patient entirely under our physical control. We then attempt to introduce the tube which has previously been immersed in water—no other lubricant is necessary. With our left arm around the back of the patient's neck we hold the proximal end of the tube between the thumb and index of the left hand—the tube running through the palm of this hand and the opening of the tube away from us This left hand is kept close to the patient's mouth. The tube, held this way, insures us against any of the stomach-contents spurting on us. The distal end of the tube—that part which goes into the stomach—is now taken between the thumb and index fingers of the right

hand, in the manner in which we hold a pen, and is introduced into the patient's mouth, which must not be opened any wider than is absolutely necessary, letting the tube pass all the time between the flexed third and fourth fingers of the left hand. The object of this last procedure is to limit the side motions of the soft tube and prevent kinking; it gives a certain degree of stiffness to the soft tube. As soon as we believe the tube to have reached the posterior pharyngeal wall we tell the patient to swallow and keep on breathing deeply. The tube is now fed into the stomach, the tube still passing between the third and fourth fingers of the left hand. It is not necessary to have the patient protrude his tongue or put our finger, as a guide, into the patient's mouth. The cyanosis of the patient, already mentioned, need cause no alarm as it is due only to a momentary cessation of breathing caused by the effort to expel the tube, in which effort the patient might succeed did we not hold the tube with the right hand.

This is my usual way of introducing the stomach tube. Whenever this method fails, and this happens very seldom, I use my stomach-tube director, which was described originally in the *Medical Record,* Aug. 29, 1896, and again in No. 24 of the *Berliner klinische Wochenschrift* of last year. That cases occur every now and then where it is impossible to introduce the stomach-tube ordinarily is a fact admitted by Riegel, Fleiner, Boas, Ewald and others.

The advantages of the instrument are two in number—it may be used as a director and it enables us to entirely dispense with the voluntary cooperation of the patient. As a director it absolutely prevents the stomach-tube from going anywhere else but into the esophagus, thus excluding the possibility of its entering the larynx. All that is to be done to insure safety is to bring the director with the tube inserted well back to the posterior pharyngeal wall, and to push down the tube with the left hand. The time required for arranging the director and getting the stomach-tube into the stomach should hardly exceed one minute. As this director dispenses with the cooperation of the patient, its utility in children, nervous patients, in the insane, and in attempted suicide is apparent

In ordinary cases the director could be removed as soon as the stomach-tube is about one inch beyond the epiglottis; *i. e.*, as soon as the sensitive parts of the fauces, pharynx and epiglottis are passed. But in cases of attempted suicide, the director must be left in the mouth during the whole washing, when it acts at once as mouth-gag, tongue-depressor, and director.

Have the aspirating rubber ball conveniently at hand and just as soon as the tube is in the stomach catch hold of the aspirating ball with the free right hand and after compressing it connect it with the stomach-tube. All this time the left hand remains busy holding the proximal end of the tube; the getting hold of the aspirator, the adjusting and connecting it must all be done quite rapidly with the right hand only. In removing the tube from the stomach we again have the tube pass between the third and fourth fingers of the left hand, being very careful to catch the stomach end of the tube. If we merely pull the tube out, the stomach end, as it comes out, will swing around and soil both ourselves and the patient.

136 East Seventy-eighth Street.

THE PATHOLOGY AND TREATMENT OF BILOCULAR STOMACH, WITH A REPORT OF TWO CASES.[1]

BY CHARLES GREENE CUMSTON, M.D.,

OF BOSTON, MASS.;

VICE-PRESIDENT OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS; HONORARY MEMBER OF THE SURGICAL SOCIETY OF BELGIUM, ETC.

WITHIN the last four years it has been my privilege to have under my care two patients with bilocular stomach, and I think, from the relative infrequency of these cases, and from the fact that surgery of the stomach is now seriously calling the attention of the surgeon, that no apology is necessary on my part for presenting before this learned body a few remarks on the pathology and the treatment of this interesting abnormal condition and recording somewhat in detail the histories of my two cases.

At the present time I believe it is generally admitted that bilocular stomach may be either congenital or acquired, but although the pathology of the acquired form is now fairly well understood there is a difference in opinion regarding the etiological factors of the congenital variety. That a congenital type of bilocular stomach does exist is certain, since this condition has been found in the fetus by Sandifort. Meckel, from the embryonal point of view, has given the explanation that this congenital defect must be regarded as the result of an insufficient development of the organ and that it is possible that the lamina which early in embryonal life form the stomach are undeveloped. It is also possible that this anomaly of the stomach results from the coalescence of half of the stomach wall and half of the intestine, which in this instance do not come together fully; or the mass from which the two stomach laminæ are derived does not undergo a complete division. In the *Journal of Anatomy and Physiology,* Vol. 17, is to be found a very comprehensive discussion as to the various possible ways in which a congenital bilocular stomach may arise, written by Roger Williams and entitled "Cases of Congenital Contraction of the Stomach, with Remarks." He bases his memoir on the observations made by many anatomists who have occasionally found a mild form of contraction in the middle of an otherwise normal stomach, but along with this another narrowing has been present which separated the antrum of the pylorus from the remainder of the stomach, in such a manner that the organ formed three pouches. These were easily demonstrated when

[1] Read before the American Association of Obstetricians and Gynecologists, Cleveland, Ohio, Sept. 17, 18 and 19, 1901.

the stomach was inflated. Since there also occasionally occurs a third narrowing arising in the region of the cardia, which according to Williams separates the greater cul-de-sac from the remainder of the stomach, according to this authority, it results that the organ may be divided into four sections by three strictures.

This explanation conforms with the opinion of physiologists, who assume that under normal conditions the stomach presents temporary contractions at the points named during the process of digestion, and who base these opinions on the results obtained from necropsies performed immediately after death, especially where this event occurred suddenly during the process of digestion and which demonstrated that the stomach presented two or three contractures. Now, inasmuch as the points where the strictures occur in congenital sacculated stomach are seated just at these places where physiological constrictions occur, Williams explains them as being exaggerations of the temporary physiological constrictions.

Rokitansky mentions as congenital defects of the stomach circular strictures at the cardiac or pyloric end of the organ and also, in rarer instances, stomachs which are divided into several compartments by rings of sclerotic tissue.

Lesshaft states that in some instances the stomach may take on the aspect of the small intestine and these strictures cannot be compensated for; some authors are of the opinion that they are due to a special development of the transverse muscular fibers. Mazzotti has recorded a case of a congenital bilocular stomach in a woman fifty years of age which in his opinion had been produced by an unusual development of the transverse muscular fibers in a certain point in the wall of the organ and which were the cause of the stricture. In another instance recorded by Saake, this authority was able to demonstrate the congenital origin of the stricture of the stomach by dissecting out two abnormally developed bundles of muscle which were transverse in direction and, according to this authority, demonstrates the physiological torsion of the stomach during its development if this localized overgrowth of bands of muscle fibers be considered as a vice in formation during the embryonal period.

On account of the various segmentations which the human stomach may occasionally give rise to, Cruveilhier and other authorities went so far as to assume that there existed an analogy between the human stomach and that of the ruminantia, but on the other hand Hudson doubts, and in all probability he is quite justified in so doing, the theory that this deformity represents an atavistic tendency. He clearly demonstrates that such defects are never met with in the higher orders of monkeys and also he believes that there is a great difference between a division into two similar parts and the highly differentiated stomach of the ruminating animals.

In 1882, Carrington presented three specimens of congenital bilocular stomach to the Pathological Society of London and he discussed the question as to the possibility of the condition being produced by an abscess during fetal life, which proposition he advanced from the fact that abscess of the stomach walls had been met with in the newly-born. He quoted a case observed by Goodhart in which a child had died of an abscess of the stomach thirty hours after birth, having hematemesis for a symptom.

Guillemot traces the etiology of congenital bilocular stomach to an abnormal development in the arterial supply to the organ. This is frequently observed and results in a separate blood-supply to each part of the stomach.

In the case of an acquired bilocular stomach several etiological factors are to be considered and first of all I would mention gastric ulcer, which, as we all know, may undergo the process of repair with the formation of a linear cicatrix involving part of the circumference of the stomach, and according to Grünfeld bilocular stomach represents thirty per cent. of those changes of shape of the organ due to an extensive process of cicatrization. I would add, however, that this author in his extensive statistics included the very mildest instances of circular contraction.

Lunnemann believes that a large majority of cases of gastric ulcer heal by a process of cicatrization, and if the ulcer has only produced a very limited defect in the wall of the stomach we then meet the characteristic white, flat, radiating cicatrices which finally result in the contraction of the mucous membrane in the neighborhood, drawing it toward the former lesion and producing radiating folds of the gastric mucosa. If, on the other hand, extensive ulcers undergo cicatrization prior to the occurrence of erosions or perforation of the blood-vessels, the result will be extensive changes in the shape of the stomach and if the ulcer was situated toward the middle of the organ the resulting cicatricial contraction will produce the characteristic hour-glass stomach.

In these cases the stomach forms two sacs which communicate the one with the other by a narrow orifice, and the only essential condition for the development of a typical bilocular stomach following an ulcer of the organ is that the site of the causative pathological process should be about at the middle of the lesser or larger curvature and extend more or less over the anterior or posterior wall of the organ. Other conditions that should be taken into consideration are the long duration of the ulcer, its slow cicatrization or its transverse extension in relation to the longitudinal axis of the organ. It should also be borne in mind that during the process of cicatrization of gastric ulcers extensive adhesions may be developed between the stomach and the neighboring viscera.

Rasmussen has called attention to what he terms a pressure sulcus in the etiology of acquired bilocular stomach and establishes a direct

causative relationship between the conditions and also a connection between gastric ulcer and pressure sulcus, considering the former lesion as an intermediary link for the formation of the hour-glass stomach. This author is at variance with the general opinion that strictures of the stomach which are observed following the presence of gastric ulcer are only due to the cicatricial contraction of the ulcer and this same authority asserts that in many cases the pressure sulcus of the liver continues over the stomach following a rather oblique direction downward from the middle of the lesser curvature or a little nearer the pylorus, toward the larger curvature, where a distinct impression can be found.

Now from the fact that Rasmussen found cicatricial tissue following gastric ulcer in the middle of the lesser curvature or somewhat nearer the end of the pylorus, that is to say, just at the point where the pressure sulcus is situated, in the large majority of cases, and since he was also able to demonstrate its presence in all cases of cicatrices of gastric ulcer after his attention was called to this sulcus, he is of the opinion that the latter sulcus represented an important etiological factor of gastric ulcer which consequently would have to be considered as the result of pressure necrosis.

According to the same authority this pressure sulcus of the stomach is capable of directly producing more or less well developed strictures of the organ. When large cicatrices are absent, Williams has denied that the production of bilocular stomach could result from the use of tight-lacing in the female for the simple reason that were this the case this condition would be far more frequently encountered. Hirsch, while not completely repudiating the theories of Rasmussen, believes that although occasionally slight anomalies in the shape of the stomach may be occasioned by pressure from the left costal border, and that over those regions of the stomach which are subject to pressure from corsets a certain disposition for the formation of gastric ulcer is quite liable to be created, still this mode of origin appears rather improbable when we consider the advanced degree of stricture formation in the stomach where the stenosis may have contracted down to such degree as only to admit of the passage of a finger or a pencil. The very large amount of cicatricial contraction resulting from the larger and more extensive gastric ulcers is quite sufficient to explain the etiology of a large number of cases of acquired bilocular stomach.

Bilocular stomach may be produced by a corrosion of the gastric mucous membrane from the ingestion of acids or alkalies, but the only case that I am aware of in which operation was undertaken for its relief is the one recorded by Klein. The patient was a female, twenty-seven years old, who had tried to commit suicide by swallowing concentrated hydrochloric acid and whose stomach was immediately washed out when she was taken to the hospital. She vomited some blood for a few days, but was discharged at the end of a fortnight, at which time she could swallow small pieces of meat. This improvement did not continue long and one afternoon she vomited the food taken. The treatment then consisted in passing bougies. The condition, however, getting worse, it was decided to operate upon the supposition that there was a stenosis of the pylorus. When the peritoneal cavity was opened, a few friable adhesions were found between the stomach and the peritoneum, but the stenosis was near the cardia about three finger-breadths from the pylorus. It was a very fibrous stricture giving rise to a typical hour-glass stomach, the stenosis being especially marked on the larger curvature. By invagination the lumen of the stricture would hardly admit the tip of the finger. The muscular walls of the cardiac region of the stomach had undergone considerable hypertrophy. As the duodenum could be easily brought over to the cardiac region of the stomach gastroduodenostomy was successfully performed.

Rudnew has recently called attention to syphilitic lesions of the stomach. They are produced either in consequence of the primary changes taking place in the gastric mucosa or from a pathological process arising in the serous membrane. Contraction of the newly-formed granulation tissue produces after a certain time a great diversity of deformities of the stomach, among which may be mentioned circular bands of fibrous tissue giving rise to a bilocular stomach or even a plurilocular variety. Einhorn distinguishes three forms of syphilitic affections of the stomach: (1) Syphilitic gastric ulcer; (2) syphilitic neoplasms of the stomach, and (3) syphilitic stenosis of the stomach.

I personally should admit without any hesitation that syphilis is probably an etiological factor in many cases of bilocular stomach and stricture of the pylorus, because other experiences in general abdominal surgery have convinced me that this potent and versatile poison is responsible for a large number of heretofore unknown surgical affections of the abdominal and thoracic viscera, but unfortunately up to the present time only a few cases of bilocular stomach can be with certainty traced to syphilis.

Carcinomatous affections of the stomach are quite liable to produce the bilocular variety and it may be assumed with a fair amount of certainty that cancer frequently causes this condition, which is easily understood when we recollect the great tendency of chronic gastric ulcer to undergo carcinomatous transformation. It is probable that when a bilocular stomach results from carcinoma of the organ the neoplasm is of the scirrhus variety and by contraction produces a stricture similar to that produced by cicatricial tissue.

In considering the pathology of bilocular stomach, we must discriminate between the congenital and acquired forms. The congenital form is to be distinguished from the latter in that it

is usually free from adhesions with the neighboring organs and that the stricture is longer and is not formed of cicatricial tissue, but of the normal structures forming the walls of the organ. The congenital variety recalls very closely the stomach of various rodents, such as the mouse, and where several pouches are found they closely resemble the stomach of the ruminantia, and since many do not have the shape of the hour-glass stomach, properly speaking, the term "segmented stomach" would, I believe, be far more appropriate.

In the congenital varieties, the cardiac part of the stomach is usually larger than the pyloric. The strictured part connecting the two pouches is glossy white, and as I have already mentioned is longer than in the acquired variety. Microscopically, no cicatricial formation can be discovered and only atrophy of the gastric mucosa, more particularly of the glandular tubes, can be seen.

Gastric ulcer has been met with in congenital bilocular stomach and has been situated at the site of the stricture, but these ulcers are secondary in origin and are probably produced by the pressure of the food passing through the strictured part of the organ.

As most gastric ulcers develop in the lesser curvature, that type where the sulcus of the stricture runs from the greater curvature to the smaller is by far more frequent. The result is that the stomach is divided into two fairly equal cavities which communicate at the lesser curvature, diverging from each other toward the greater curvature. The position of the contracting cicatrix will, of course, in many cases divide the stomach unequally and in several instances the cardiac pouch has been found much larger than the pyloric one, but it is a question in this case whether the stomach is divided into two unequal parts or whether the cardiac pouch has not become dilated by the accumulation of food after stenosis had taken place or for some reason before the cicatrix had formed. In this dilatation, which is such a natural sequence of stricture and which corresponds so closely with what takes place in stenosis of the pylorus, it is probable that in bilocular stomach the cardiac pouch becomes increased in dimensions by the mechanical dilatation produced by food.

This condition is, however, not always met with and in the beginning the cardiac pouch will often present a considerable thickening of its muscular coat due to an hypertrophy from overwork. The explanation is simple: because of the increased difficulty in the passage of the food the cardiac pouch is put upon a strain and hypertrophy from overwork is the natural outcome. Lunnemann found that the strata of circular muscles measured from two to two and one-half millimeters in thickness, while in the pyloric pouch it measured from only one to one and one-half millimeters. This amount of hypertrophy is absolutely essential to life.

It is worthy of note that the cardiac pouch frequently gives rise to serious trouble, due to a dilatation that results from an atrophy of its walls from inactivity and to muscular insufficiency. In some reported cases it was seen and could also be demonstrated clinically that the second stomach was dilated. A classical example is the case reported by Langerhans of a man, forty-seven years old, who had been afflicted with disturbances of the stomach for a number of years. The necropsy showed that the stomach was divided into two pouches, the pyloric pouch being very much larger than the cardiac. Such a marked degree of atrophy can be explained from the fact that the cicatricial tissue interrupted the vascular and nervous supply of the stomach, the result being that the movement of the muscular coat exhausted itself at the point of cicatricial contraction and was no longer able to transmit its activity to the second pouch which produced an atrophy from inactivity, because the food being forced into the second stomach remained in the latter for some time and was the cause of a marked gastrectasis.

The various conditions which occasion the pathological symptoms are consequently based (1) on the fact that the cardiac stomach is smaller than the pyloric; (2) that the contracting cicatrix draws the greater curvature upward, forcing the cardiac pouch to raise the food to the level of the cicatricial opening and being much easier exhausted at this high point; (3) that the stomach is in a state of ectasis, and (4) the communication between the pouches is often times reduced to a very narrow canal. In reported cases the lumen of the channel connecting the two pouches has been found to vary from the size of a lead pencil to an opening sufficiently large to admit the passage of four fingers.

When the lumen of the stenosed part is very small, the patient will soon die from inanition, and this condition becomes all the more serious owing to the fact that the pyloric pouch undergoes a torsion on its axis, being partially fixed between the cicatrix and duodenum.

Microscopically the cicatrix of a gastric ulcer which has produced a stenosis of the stomach shows passive changes, distortion of the gland-tubes from displacement, as well as active and luxuriant tissue proliferation which is most pronounced in the immediate vicinity of the cicatricial tissue, but not in the cicatrices themselves. Lunnemann found a considerable increase of glandular bodies, both at the margins of the cicatrix and in more distant parts of the stomach walls where the mucosa was otherwise perfectly normal, in a case of bilocular stomach, and considers this as the expression of the vascular hyperemia due to the ulcerative process. In other cases the mucous membrane has been found normal in the region of the ulcer, excepting in those instances where a carcinomatous infiltration of the tissues was present. The remainder of the gastric mucous membrane in most cases usually reveals the microscopical characters of a glandular gastritis.

Hauser, whose competency in the matter of pathology of the stomach is without question, has had occasion to make microscopical studies of the cicatricial tissue taken from bilocular stomachs, and he has found that it is accompanied by an enormous increase and proliferation of the glands of the mucosa which has become contracted, and this extends over the entire cicatrix and somewhat beyond it. A similar growth of glands is also met with in the mucous walls of very extensive chronic gastric ulcer which never completely heals. Beside the luxuriant growth of glands a change in their epithelial lining occurs at the same time, the normal epithelium of the pepsin glands being replaced by either cylindrical or cubical epithelium. From a very careful study Hauser concluded that the luxuriant growth of glandular structures appearing at the time of cicatrization of chronic gastric ulcer is independent of any secretory influence and that these results arise from the combined effect of an increased supply of nourishment during the process of ulceration and cicatrization, as well as from a disappearance of the inflammatory exudate which surrounds the glands, because by this means the production of the epithelium of the glands is increased and at the same time the physiological resistance of the neighboring tissue is weakened. The passive torsion of the tubes of the glands contributes toward their increase and development while the continuation of the growth to an unlimited degree is prevented by the progressive cicatrization and condensation of this tissue and, finally, the glands disappear. On the other hand, if solid cicatrization does not take place an exuberant glandular growth continues and the ultimate outcome will be a transformation into carcinoma. Thus, between a carcinomatous change of the epithelium of the glandular elements of the gastric mucosa, as well as an atypical abundant growth of the glands themselves which occurs every time an ulcer of the stomach undergoes cicatrization, there only exists a *difference in degree* and Hauser has proven the well-known clinical fact that a gastric ulcer may and often does transform into carcinoma.

Adhesions with the surrounding viscera are frequently met with in cases of bilocular stomach and are usually due to the process of cicatrization of a former ulcer of the organ. In some instances they are very extensive and bind the stomach to the liver, pancreas or the anterior abdominal wall.

When the opening between the two pouches in bilocular stomach is sufficiently large the patient may be free from any symptom of a gastric lesion and persons may attain quite an advanced age and die from some other cause, so that the pathological condition is only discovered at autopsy and it is probably that if all the necropsy records of the large hospitals throughout the world could be consulted a very considerable number of both congenital and acquired bilocular stomachs could be found. Since a congenital hour-glass stomach predisposes its owner to the development of an ulcer of that organ, it may easily happen that this congenital defect does not present any symptoms in early life and the patient will only present gastric disorders after an ulcer has formed. Such an instance has been put on record by Sievers in which a patient, twenty-six years of age, had been well up to that time, when a gastric ulcer developed and caused death from perforation.

In those cases where a bilocular stomach has been acquired, symptoms arise which can be clinically divided into two groups. The first are simply those to which a gastric ulcer gives rise; after the lesion has existed for many years, or after several recurrences have taken place, the second group of symptoms appears upon the scene and indicates the presence of bilocular stomach.

These symptoms are especially produced by a retention of the stomach contents, just as in the case of pyloric stenosis. Food, and more especially solids, such as bread and meat, remains lodged in the cardiac pouch and there produces a sensation of marked distention. After a meal, vomiting may set in immediately or in other instances it may occur in the early morning before breakfast. Not infrequently the vomitus will be found to contain food which has been taken one or several days before, a significant fact, because it indicates a stenosis somewhere in the stomach. Foul-smelling eructations also occur and simply indicate decomposition of food going on in the stomach. In most cases the appetite remains good and, as a rule, a liquid diet will not give rise to these symptoms.

The patients suffer from great thirst, and it may also happen that in this stage of the disease hematemesis, which may not have occurred for years, suddenly makes its appearance, in some cases so violently that the patient dies. As the affection progresses, gastric pain becomes unbearable and for this reason the patients refuse food, the result being that the loss of flesh is great and the patient takes on all the appearance of a malignant cachexia which leads the surgeon to the erroneous diagnosis of malignant disease of the stomach.

A very important symptom is a feeling of fulness in the stomach even after ingestion of small quantities of food and this symptom is only relieved after vomiting has occurred. Some patients describe their sensation as if the stomach became contracted and they may also suffer from pains during peristaltic movements of the organ which occur a few hours after digestion and which may finally become continuous as the affection becomes more marked. This symptom depends upon the condition of the cardiac pouch and of the kind of stenosis present. Beginning atrophy and muscular relaxation of the cardiac pouch give rise to daily vomiting.

Although the present methods of clinical examination have not attained that pefection by which the presence of a bilocular stomach can

be made out with any degree of certainty, it is nevertheless possible to diagnose this condition in quite a number of cases if various methods are combined. There is no doubt in my mind but that many diagnoses of dilatation of the stomach from pyloric stenosis or diverticula of the stomach or of the esophagus have been made, when in reality the true condition was a bilocular stomach; and even when the abdomen has been opened this condition may be easily overlooked when the cardiac pouch is small and situated near the diaphragm along with the cicatrix.

Simple inspection of the abdomen will rarely aid us in diagnosis, but we may be able to obtain some idea of the condition if the stomach is artificially inflated. If the abdominal walls are thin and flabby, and if the stenosis is not sufficiently narrow to prevent the passage of gas and water through it, it is easy to make the stenosis plainly visible by inflating the stomach.

It should be borne in mind that in those patients in whom the stenosis is very marked the cardiac pouch alone will become inflated. It may also happen that the gas remaining in the cardiac pouch will show the convexity of the stomach above the umbilicus, but the pyloric portion containing fluid will give rise to a succussion sound below the umbilicus, so that under these circumstances a differential diagnosis must be made between dilatation of the intestine and bilocular stomach. It is also important that the outline of the inflated stomach on the right remains in the median line or somewhat to the left of it, which does not correspond with the position of the pylorus. Peristaltic movements in the gastric region are of no value in the diagnosis of the affection we are considering. By palpation much can be ascertained. The epigastric and umbilical regions are often painful on pressure and not infrequently a resisting mass can be made out, above which a high pitch percussion sound may be elicited, while on both sides of this high pitched area of percussion a tympanitic sound is obtained. In some cases a tumor may be palpated in the left hypochondrium varying in size from one case to another, having indistinct outlines and being painful on pressure. This tumor may be due to cicatricial tissue in the bilocular stomach or to muscular spasms of the organ.

Much importance has been attributed to the splashing sound which is frequently met with in the region of the umbilicus, but it is in no way characteristic of bilocular stomach and simply indicates that the organ is dilated. Jaboulay has described a diagnostic sign which is different. In his case the splashing sound continued below the umbilicus after the stomach had been filled with water, while it disappeared in the upper epigastric region, that is to say, in the cardiac pouch. Tympanitic sounds remained in the pyloric pouch while in the cardiac pouch they became dull. This interesting phenomenon should be carefully looked for, but naturally if taken alone is quite insufficient for a diagnosis.

We should never neglect to try to elicit the splashing sound while the stomach is empty, care being taken to remove all liquid from the organ by the stomach-tube. Now, if this has been done and a splashing sound is obtained, it indicates in all probability that we are dealing with a bilocular stomach from the fact that the pyloric pouch has not been emptied by the siphon and contains liquids and gas. If a bilocular stomach be washed out, the water which has been introduced may not return, or a lesser amount than what was introduced runs back, a fact which can be easily explained from the liquid in whole or in part passing through the stricture and remaining in the pyloric pouch.

The use of the X-ray has been applied in the diagnosis of gastric diseases, especially by Jaworsky, and by combining the usual methods of examining the stomach he was able to diagnose several cases of bilocular stomach.

The chemistry of the stomach will also aid us in the diagnosis and should never be neglected, for in the majority of cases examination of the gastric contents showed that there existed entire absence of free hydrochloric acid or only traces of it. The acids of fermentation have been present in some cases. In cases where the gastric ulcer which had given rise to bilocular stomach was comparatively recent there was hyperacidity of the gastric contents. The absence of free hydrochloric acid and the presence of the acids of fermentation in the majority of cases of bilocular stomach is to be explained by the existence of a chronic gastritis. This very circumstance is rather surprising if one accepts the usual views held forth, that hyperacidity is an important factor in the formation of ulcerative processes of the stomach. It may be that the absence of free hydrochloric acid with the presence of the acids of fermentation will greatly aid in the diagnosis of bilocular stomach, but on this point more researches will have to be made, and at present it cannot be said to be of positive value.

As to the differential diagnosis, stenosis of the duodenum should be considered. The duodenum above the stenosis is frequently dilated to such an enormous degree that it may resemble a second stomach. This dilatation may in some instances be diagnosed before opening the abdomen, particularly in those cases where bile and pancreatic juice can be demonstrated in the gastric contents. In stenosis of the duodenum the pylorus may still carry on its normal functions, in which case the pylorus represents the orifice between the stomach and duodenum, which on superficial examination may have all the appearances of a bilocular stomach. When there is pyloric insufficiency the stomach and duodenum form one vast pouch.

When the stenosis is limited and does not cause any marked impediment to the onward progress of food, the prognosis of bilocular stomach cannot be said to be serious, but in all cases where the stenosis is marked the outlook for the patient is most unfavorable unless an op-

eration is undertaken. Death will occur when the stenosis has arrived at such a degree that a torsion on its axis takes place. From what I have already said there are quite a number of cases of bilocular stomach which never receive medical or surgical treatment during life for the simple reason that a correct diagnosis has not been made, but as soon as the condition produces symptoms, the only proper treatment is operative. The same indications apply to bilocular stomach as they do for gastric ulcer or of carcinoma of the stomach, either for their radical cure or to alleviate the complications to which these various lesions give rise.

An operation should be undertaken when a patient presents continued pain, repeated vomiting and other dyspeptic disturbances or when symptoms, such as increasing emaciation and cachexia, make their appearance. Several operations have been recommended and performed for the relief of bilocular stomach or its cure. In the first place a resection of the stricture with suture of the two pouches has been recommended, the new opening thus obtained being sufficiently large to allow the easy onward progression of food. Along with resection, gastrorrhaphy may possibly be indicated if there is a very considerable degree of dilatation of the organ. A gastroplastic operation performed identically in the same manner as the Heinecke-Mikulicz operation for stenosis of the pylorus has given a number of very gratifying results. Gastrogastrostomy is also indicated and consists in making a free anastomosis between the cardiac and pyloric pouch immediately under the stenosis without dealing with the latter. Gastrojejunostomy and gastroduodenostomy have also their indications, as well as operative and non-operative gastrolysis, the latter operation being only indicated when the symptoms accompanying bilocular stomach are chiefly due to extensive perigastric adhesions, the stenosis being sufficiently patent as not to interfere with the process of digestion. Digital dilatation as recommended by Loreta for stenosis of the pylorus has been done at least on one occasion some years ago, but would appear to be a useless and irrational mode of treatment

Regarding indications for the various operative procedures already mentioned, I would say that the surgeon must not only be guided by the simplicity, security and speed of the operation and by the favorable results obtained, but he must also take into consideration the given case as the anatomical changes vary tremendously from one case to another and what I have already remarked in discussing the indications for operative treatment of carcinoma of the stomach at the Annual Meeting of the Massachusetts Medical Society last June will certainly apply to the operative treatment of bilocular stomach, namely, that *no operation can be decided upon before the abdomen has been opened and the condition of affairs thoroughly ascertained, and it is only after the surgeon has become perfectly familiar with the anatomical conditions present that he may select the operation the most applicable under the given circumstances.*

Take, for example, a case where a large area of the walls of the stomach has become bound down to the pancreas, the liver, spleen or other viscera, it is very evident that a dissection of the stenosis would be impracticable and to say the least a most dangerous proceeding. Excision of the entire stricture followed by gastrorrhaphy can only be undertaken in very rare cases and so far as I am aware no operator has up to the present time performed it for the cure of bilocular stomach because this method is more complicated than the others and promises no better results. Gastroplastic operations are not to be undertaken if the cicatrix at the pylorus or in the middle of the stomach is very extensive or if the greater part of the mucosa is ulcerated or has undergone cicatricial changes so that sutures would not hold. If, however, the stenosed portion of the organ is small and movable so that it can be resected, and if after this has been done there still remains enough normal stomach wall at the point of the resection to effect a communication by means of a Heinecke-Mikulicz operation, the result will be extremely gratifying if the cardiac pouch has not undergone too great a degree of atrophy. I am very well aware that there are some operators who have had poor results from this operation in bilocular stomach, but I nevertheless must confess that my experience with it in the case appended at the end of this paper has been most gratifying.

I presume that taking all things into consideration, the most generally applicable procedure, at least in a large majority of cases, is gastro-anastomosis according to Doyen's or Woelfer's methods. By these operations two very important points are gained, first, a wide communication between the cardiac and the pyloric pouches and, secondly, the dilated cardiac pouch is relieved of its very difficult part of propelling the stomach contents forward, because the fact that the anastomosis is situated low down renders the onward progress of the chyme easy. Gastro-anastomosis is, I believe, indicated in all difficult cases of bilocular stomach, especially when the stenosis is long and narrow and where cicatricial atrophy of the cardiac pouch has occurred and where there are a large number of adhesions. Compared with resection, gastro-anastomosis is superior in that it can be more rapidly performed, and compared with gastro-enterostomy it is, I believe, a more perfect operation, because it re-establishes the stomachal digestion in its entirety. Compared with a gastroplastic operation, it is more advantageous in that it creates a wider communication between the two pouches and that the operation is not performed at the site of the cicatricial tissue. The peristaltic movements of both pouches are brought into more intimate relation and, what should be particularly borne in mind, the value of gastro-anastomosis increases the nearer the stenosis is to the cardia, because resection of the stomach and gastro-enterostomy

cannot be carried out so easily when the conditions are such as those just named.

As every other operation, gastro-anastomosis has its limits of application. It cannot be undertaken in those cases where the pyloric pouch is so small that an opening cannot be made in absolutely sound tissue—that is to say, at a sufficient distance from the stenosis.

In all cases where the proper conditions for the performance of the first three methods described are not present or where the stenosis is embedded in adhesions binding it to the surrounding parts, gastrojejunostomy is indicated, principally because the area of cicatricial tissue is entirely avoided during the operation. Gastroduodenostomy is not a procedure that I believe can ever take the place of gastrojejunostomy in cases where the adhesions are thick and strong, because the duodenum and its mesentery are bound down posteriorly; but when the descending portion of the duodenum and the cardiac pouch of the stomach can be easily approximated, then I think that gastroduodenostomy is the operation of choice and far superior to any other.

Operative and unoperative gastrolysis have occasionally their indications. Operative gastrolysis should be carried out in such a manner that after the adhesions between the stomach and the adjacent organs have been broken down no raw surface should remain, and for this reason in order to have a successful result I believe that all adhesions should be tied off close to their base between two catgut ligatures and as much of the tissue should be resected as is possible. The use of the thermocautery in breaking up lesions and for the prevention of their recurrence is, I think, to be condemned.

Non-operative gastrolysis consists in frequently inflating the stomach, the object in view being to stretch or tear fresh adhesions that are formed between the stomach and the neighboring organs. This treatment has given one or two good results in cases where it was tried and may be resorted to when indications for its use are present.

Case I.—A female, aged forty-nine years, a cook by occupation, applied at my clinic at the Tremont Dispensary in October, 1900, with the following history: No hereditary affection could be discovered. At the age of twenty years she began to work as cook and a few years later developed what in all probability was a severe chlorosis. After a prolonged treatment, the patient's health began to improve and she remained fairly well for a year or two, when at the age of twenty-eight years she began to present gastric disturbances. These symptoms consisted in severe pain in the region of the stomach, particularly after the ingestion of solid food. This was followed by vomiting, the vomitus sometimes containing blood, but we could not discover in the patient's history any distinct description of a true hematemesis.

According to the patient's story, she suffered from her stomach off and on until the age of thirty-six or seven years, since which time the severe pain and vomiting have been almost completely absent, but within the last year another set of gastric symptoms have begun. At present the patient cannot retain any food. After each meal, within an hour or two the patient complains of a heavy feeling in the epigastrium and suddenly, after a minute or two of sharp pain, her food will be vomited spontaneously. The vomiting is really more like a regurgitation. As the patient had not retained much food during the last three months, she was extremely weak and emaciated. She had a straw yellow color of the integuments and with her drawn features presented, to all outward appearances a subject in an advanced condition of carcinomatous cachexia. Her normal body weight had been about 150 pounds, but the patient stated that in the last three months she had lost thirty-seven pounds. Her tongue was coated with a white fur, the mucous membrane of the mouth was dry and the patient was troubled by a constant thirst. A marked constipation had existed for many years. Appetite poor. Sleep fairly good. The patient is not troubled by headaches.

On inspection nothing special was noted. Palpation of the stomach in an empty condition gave rise to considerable pain. Insufflation of the stomach showed that the lower limits of the organ extended to the umbilicus. The distention caused great pain. By palpation I thought that I could make out a distinct mass situated in the middle of a line drawn from the umbilicus and right costal arch, consequently in the region of the gall-bladder.

The patient was ordered a test breakfast which showed free hydrochloric acid in the gastric contents with an absence of lactic or other acids of fermentation. Blood-examination showed hemoglobin, 7 per cent.; polynuclears, 77 per cent.; mononuclears, 22 per cent.; eosinophiles, 1 per cent.; no leucocytosis.

I endeavored to ascertain if Jaboulay's sign could be obtained in this case, but it was absent and my diagnosis wavered between a bilocular stomach, of which from my examination I had no evidence, and carcinoma of the stomach arising from a former gastric ulcer. The patient was advised to submit to an early operation, which was performed a few days later.

After the abdomen was opened in the median line it was found that the stomach was bound by a large number of adhesions to the omentum and transverse colon, while the pylorus was bound down to the gall-bladder; after carefully freeing the organ from the omentum, colon and gall-bladder it was found to be a bilocular stomach, the cardiac pouch being about twice as large as the pyloric. The connecting stenosed canal was extremely thick and hard. From the conditions present I decided that a gastroplastic operation was naturally out of the question and that resection, followed by gastrorrhaphy, was inapplicable on account of the unequal dimensions of the

pouches and also because of the apparent atrophy of the stomach walls, which probably would not allow the sutures to hold. Gastrogastrostomy was for the same reasons to be rejected. The omentum minus was torn through and a loop of jejunum was seized and sutured to the posterior wall of the stomach—in other words, a posterior gastroenterostomy was done, Doyen's method having been found impracticable in this case. The opening between the stomach and the intestine was about four centimeters long, the anastomosis being done with three layers of sutures of fine celluloid thread. The omentum minus was closed with fine catgut and the abdominal wound closed by two layers of catgut for peritoneum and fascia with silkwormgut for the skin. In the evening the temperature was 39°C., pulse 100. The patient had vomited little since the operation and had voided about 200 c.c. urine.

To make the history of this case short, I would say that the patient made a very good, though slow convalescence, being discharged about nine weeks later in a satisfactory condition.

I saw this patient six months after the operation, at which time she had gained eighteen pounds in weight and was beginning to have a fairly good digestion, most functional disturbances of the stomach having disappeared. She was still constipated, requiring nightly medicine in order to procure a movement on the following day.

The following case has already been published in the *New York Medical Journal,* December 9, 1899, but I will reproduce it on this occasion in order to make this paper more complete.

Case II.—Female, aged forty-seven years, was first seen in March, 1898. At that time she was complaining of a severe pain in the right side and in the epigastric region, and of occasional vomiting after eating. The patient was a thin, anemic subject, in a rather despondent condition of mind. Examination revealed what was believed to be a dilated stomach in a state of ptosis and a movable right kidney. On the supposition that this was a case of gastroptosis and gastrectasis, the symptoms of which were exaggerated by the presence of a very movable kidney, nephrapexy was performed a few weeks later, with the result that the pain in the right side was completely relieved, but the digestive symptoms continued quite as before.

In November, 1898, the patient was again seen, complaining of her stomach, and a more careful history of the digestive disturbances was obtained, a thing that should have been done in the first place, as the symptoms were far too marked to have been neglected as they were.

At the age of seventeen the patient had typhoid fever and had suffered ever since from what she called indigestion; but at about the age of twenty-six attacks of pain in the epigastric region and vomiting began to occur, and have been more or less constantly present ever since. The attacks of gastric pain occur more especially after a hearty meal, excessive bodily exercise, or mental fatigue, but at no time was any blood vomited or passed *per rectum.* The menses have always been regular and painless. Chronic constipation of severe grade has been present for many years, and the patient has frequent attacks of frontal neuralgia. The heart and lungs are normal. Analysis of the urine gave the following results: Specific gravity, 1016; total amount in twenty-four hours, 1,200 cubic centimeters; color pale; reaction slightly acid; urea, 25.5 grams to the liter. No albumin or sugar. Abdominal viscera, excepting the stomach, in apparently nomal condition.

I would here remark that the patient's father died at the age of fifty-one of some obscure stomach trouble, from which he had suffered for many years.

A dilated stomach had been diagnosticated when the patient was first seen, but we now suspected that the gastrectasis was quite probably due to a benign, or perhaps malignant, stricture of the pylorus, because by palpation a somewhat painful mass could be detected in the left hypochondriac region, which had not been noticed when the patient was examined in March. The splashing sound could be elicited, but auscultation over the back when the patient swallowed water only showed the characteristic normal *glou-glou* sound. When the stomach had been moderately distended with CO_2 its lower border was found at about a finger-breadth below the umbilicus. The lower half of the abdomen was retracted.

The vomitus obtained during an attack of pain was a yellow mucus with a decided acid reaction. The stomach was irrigated and a test breakfast, consisting of a cup of tea, one egg, and a roll, was ordered, and the stomach contents were withdrawn two hours later. They were found to be composed of fluid containing about twenty-five cubic centimeters of the roll. After filtering, the analysis showed a considerable amount of free hydrochloric acid and a complete absence of lactic acid.

An exploratory incision was advised and accepted. The stomach was irrigated morning and evening with a 1-1,000 solution of naphthol B for one week prior to the operation, which was done on December 2, 1898. An incision twelve centimeters long was made, beginning at the outer border of the rectus muscle, midway between the tip of the sternum and the umbilicus, and was carried obliquely downward on the left side. When the abdominal cavity was exposed the pylorus was examined and found perfectly normal. At about the junction of the lower with the middle third of the lesser curve of the stomach was found a strictured portion uniting a normal lower third with a dilated upper two-thirds of the viscus. The strictured portion was about seven centimeters wide and three centimeters long, and was united to the surrounding structures by a few tough adhesions. These were broken down by the finger and a few snips of the scissors and the part liberated.

After the stomach had been well drawn out through the abdominal incision, an incision was made on the anterior aspect of the viscus in the longitudinal axis of the strictured portion. The stenosed portion would allow the passage of three fingers. The incision was continued upward and downward for about four centimeters, and when completed measured about eleven centimeters. A Heineke-Mikulicz plastic operation, as devised for the pylorus, was done, and when completed the line of union was about eleven centimeters long.

The borders were brought together by fourteen interrupted fine silk sutures which were passed through the stomach wall, but *did not include the mucosa or the peritoneum.* The silk sutures were covered by bringing the peritoneum together with a Lembert's suture of fine catgut. The peritoneum, fasciæ, and muscles were sutured with fine catgut, the skin and fat being united with aluminum and bronze wire.

The after-treatment was simple and recovery was remarkably rapid. On the afternoon and evening following the operation the patient vomited clots of partially digested blood. The next morning she was feeling well; temperature, 100.4° F., pulse 92. Vomiting of blood occurred in the afternoon, but the quantity voided was small.

On the third morning following the operation the patient, who had been fed by enemata, was allowed to have champagne and crushed ice by teaspoonful every hour. Feeding *per os* was begun on the sixth day, and gradually solid food was substituted for a liquid diet, so that just three weeks after the operation the patient was taking meat. The patient was discharged well on January 10, 1899.

I saw the patient this summer (1901), and found that she has remained in excellent health and that the functions of her stomach are apparently perfect.

871 Beacon Street.

SOME UNUSUAL LOCALIZATIONS OF TUBERCULOSIS.[1]

BY FREDERICK A. BALDWIN, M.D.,
OF ANN ARBOR, MICH;
ASSISTANT IN PATHOLOGY, UNIVERSITY OF MICHIGAN.

WARTHIN made a report in the MEDICAL NEWS of May 6, 1899, of some unusual localizations of tuberculosis which had come under his observation. He reported one case in which tuberculosis and sarcoma were co-existent in a wart of the skin, two cases of tuberculosis and carcinoma co-existent in the mammary gland, one case of primary tuberculosis of the nose, one case of primary tuberculosis of the lobe of the ear, one of primary tuberculosis of the heel, one of primary multiple tuberculosis of the brain, one of tuberculosis of a Graafian follicle, one of tuberculosis of the placenta, and one of tuberculosis of an artificial anus.

To these, I would add some others which have come under the observation of the Pathological Laboratory since that time. The material was fixed and hardened in alcohol, formalin, bichloride of mercury, or Müller's fluid, embedded in paraffin, sectioned and stained with hematoxylin and eosin, the diagnosis of tuberculosis having been made only after the tubercle bacilli had been demonstrated with the Ziehl-Neelsen stain.

Case I.—Tuberculosis of the Hypophysis: The subject in whom this was found was a young colored man, aged twenty-five years, who was admitted to the Medical Clinic of the University Hospital. His case was diagnosed clinically as acute general miliary tuberculosis. He died, and at post-mortem miliary tubercles were found macroscopically in the lungs, liver, spleen, kidneys and adrenals.

These findings were verified microscopically and when the hypophysis was sectioned, it was found to contain a small round or oval mass near the center of the posterior lobe. When the sections were stained, this mass was seen to be a circumscribed area of epithelioid tissue containing no blood-vessels. Few giant-cells were found and in the center of the mass, beginning caseation was seen. With the specific stain, scattered tubercle bacilli in small numbers were found.

I have had access to the "Index Medicus" and to the "Index Medicus Novus" and by means of these, I have looked up the literature of tuberculosis in general, acute miliary tuberculosis and tuberculous meningitis, and I have been unable to find reported a single case of tuberculosis of the hypophysis, so that, as far as I am able to know, this is the only reported case.

Case II.—Tuberculosis of the Intercostal Tissue near the Sternum, with Secondary Tuberculosis of the Axillary Lymph-Glands: This condition existed in a patient of Dr. Kinyon of Ann Arbor, with the following history: In May, 1899, she injured her sternum and an "open sore" resulted. Six months later, the axillary lymph-glands became involved and began to suppurate. The ulcer was curetted and an axillary lymph-gland was removed by Dr. Kinyon, May 24, 1900, and sent to the Laboratory for examination.

Sections of the curetting from the ulcer, showed that the floor and walls of the ulcer were made up of epithelioid tissue with very few small blood-vessels, and contained a large number of very large giant-cells with peripherally-arranged nuclei. The curetting, as a whole, showed little caseation. Sections from the axillary lymph-gland showed that its center was entirely replaced by epithelioid tissue without blood-vessels, containing few giant-cells and showing a beginning caseation.

I add this case because of the rather unusual seat of the primary tuberculosis and its secondary.

Case III.—Primary Tuberculosis of the Fal-

[1] From the Pathological Laboratory of the University of Michigan.

lopian Tube, with a Large Tuberculous Abscess in the Ovary: The patient from whom these specimens were taken was admitted to the Gynecological Clinic of the University Hospital and gave the following history: Mrs. A., Ann Arbor, Mich., aged twenty-five years, married, no children nor abortions. She has always had painful menstruation. One year and a half ago the cervix was dilated, but the dysmenorrhea showed no improvement. In June, 1900, she had "pleurisy, inflammation of the kidneys and bladder, and abscess in the pelvis." November 6, 1900, Dr. Martin removed the uterus, tubes and ovaries and sent the tubes and ovaries to the Laboratory for examination.

Gross examination showed that the tubes were greatly dilated and cystic and contained a yellowish granular material. The ovaries were swollen, covered with adhesions, and gave fluctuation. When the ovary was cut, it was found to be a large abscess containing greenish-yellow caseated material.

Microscopical examination revealed the presence of many miliary nodules in the plications of the tube. These nodules were composed of epithelioid tissue without blood-vessels, and in some nodules giant-cells with peripherally-arranged nuclei were seen. Sections from the wall of the abscess cavity showed that this wall was made up of this same epithelioid tissue without blood-vessels and contained but few giant-cells. Sections through some of the corpora fibrosa showed a beginning ingrowth of the epithelioid cells along the lymph-spaces.

Wolff, in 1894, collected all the cases then reported and found 110 cases. Since that time I have found two other cases reported, making 112. This case of mine makes 113 and another, which I expect to report in detail later because of the co-existence of tuberculosis and carcinomatous proliferation, will make 114.

Case IV.—Tuberculosis of the Thyroid Gland: This specimen came from a case which was diagnosed clinically as acute general miliary tuberculosis. At autopsy this diagnosis was confirmed by finding enormous numbers of miliary tubercles in both lungs and to a lesser extent in the spleen, liver, kidneys, adrenals and thyroid. Sections taken from the thyroid showed a small miliary nodule replacing the glandular substance. This small nodule was made up of central caseated mass surrounded by a narrow zone of epithelioid tissue containing neither blood-vessels nor giant-cells.

But few cases of tuberculosis of the thyroid have been reported. These cases have shown no clinical symptoms and have been found only as the result of thorough study of the autopsy material. Rolleston reported a case in which a large tuberculous abscess opened into the trachea and esophagus through small fistulæ. He quotes Fraenkel as having found 6 cases in 380 consecutive autopsies on tuberculous subjects. He also states that Chiari found 7 cases in 100 consecutive autopsies on tuberculous subjects, and hence he concludes that tuberculosis of the thyroid gland is not rare. Yet I have been able to find only four other cases reported, one by Perry and three by Voelker, making 18 in all. My case, then, would be 19 and it is the first that has been seen in this Laboratory in a series of over 60 consecutive autopsies of tuberculous subjects.

Case V.—Tuberculosis of the Uvula: This specimen came from a patient of Dr. Carrow with the following history: Mrs. S., aged between fifty and sixty years; a good family and personal history, and the mother of two strong muscular boys. She came to Dr. Carrow for a small nodule on the uvula. He removed it and sent it to the Laboratory for examination. The report sent back was "chronic granulation tissue probably tuberculous." He then removed the uvula *in toto* by extending his incision some distance outside the base of the uvula. Sections were made of the uvula and stained with hematoxylin and eosin and in carbol-fuchsin. Immediately under the epithelium was a granulation tissue very poor in blood-vessels. At a farther distance from the epithelium the sections showed small masses of epithelioid tissue, containing no blood-vessels. Scattered throughout these masses, and making up a large part of some, giant-cells with peripherally-arranged nuclei were found. Sections stained with the carbol-fuchsin showed tubercle bacilli in the giant-cells and a lesser number in the epithelioid tissue. In answer to the question whether the patient had pulmonary tuberculosis, Dr. Carrow informed me that she had a slight nervous cough but that he could find no evidence of tuberculosis in her lungs.

Although tuberculosis of the pharynx and larynx is of common occurrence, I have been unable to find any case reported where the uvula has shown any tuberculosis. This case, then, is unique in that it is one of the first, if not the first, case of tuberculosis of the uvula.

Case VI.—An Adenomatous Polyp of the Cervix Uteri Showing Tuberculosis: This specimen came from a patient, aged twenty-five years, with the following history: No children nor abortions. Seven or eight years ago, she "got her feet wet, took cold and had inflammation of the abdomen." For a year following, she had a continuous leucorrheal discharge which has gradually decreased in amount and now is absent. She has had no period since that time, she feels tired but otherwise is well. Examination showed that the ovaries were small and that a polyp, about the size of a cherry, was attached to the cervix. This polyp was soft, pulpy and bled freely upon the slightest handling. The polyp was removed and sent to the Laboratory for microscopical examination.

Microscopically, the specimen consisted of a large number of glands held together by connective tissue. The glands were tubular, branched and their lumina were lined by a single layer of columnar epithelium, the cells of which

possessed a finely granular protoplasm and a round or oval well-staining nucleus. Many of the cells had undergone a mucous change and the lumina of the glands were filled with a granular, stringy material staining grayish-blue with hematoxylin. The connective tissue of the polyp was made up of oval or spindle-cells, containing round or oval nuclei which stained deeply. Scattered through this connective tissue were small round or oval masses, made up of large round and oval cells with a large amount of finely granular protoplasm surrounding a bladder-shaped, lightly-staining nucleus. These areas contained no blood-vessels, but scattered through the areas were seen a few giant-cells with faintly-staining nuclei arranged peripherally in the protoplasm.

As far as I have been able to ascertain, this is the first specimen reported which shows the existence of tuberculosis in an adenomatous polyp of the cervix uteri. Two cases of tuberculosis in adenomatous polypi of the fundus uteri have been reported, one by Madlener, who cites another case but gives no reference.

Note.—Since this article has been in the hands of the editor, my attention has been called to two references of similar cases. Beyea, in the *American Journal of Medical Sciences* for November, 1901, reports a case which he calls tuberculous hyperplastic endocervicitis and which, from his description, must be similar to my case. He mentions having found other cases but does not state how many. Cullen, in his work, Cancer of the Uterus, cites three cases of tuberculosis of the cervix which had been seen at the Johns Hopkins Hospital. One was a tuberculous ulcer, another he calls a tuberculous condyloma of the cervix, and the third was a case of polypoid tuberculosis of cervix.

NEPHRECTOMY FOR SEVERE AND PROLONGED MONONEPHROUS HEMORRHAGE.

BY GRANVILLE MAC GOWAN, M.D.,
OF LOS ANGELES, CAL.,
PROFESSOR OF GENITO-URINARY SURGERY IN THE UNIVERSITY OF SOUTHERN CALIFORNIA.

H. E. W.; thirty-five years old; occupation, merchant. General health has always been good. No history of gonorrhea or tuberculosis. He had a profuse hematuria eight years ago, which came on soon after lifting a heavy body and directly after coition, continued for several days and was painless. It ceased without treatment. Two months ago he had several slight chills, with some temperature. Soon after, while urinating at night, he noticed that the close of the act was painful. The next day there was dysuria, great frequency and imperative desire. A few drops of blood passed at the close of each act of urination.

The urine was examined microscopically, and was found to contain blood and pus. After this, the hematuria was constant, clots formed in the bladder, paroxysmal pains came on in the back, and were increased by pressure over the kidneys, the right side being most painful. After a week or ten days the pain lessened, but the bleeding continued as profuse as before. The quantity of blood lost must have been great, for the patient was very anemic, very weak, and had lost thirty pounds in weight.

Examination.—Penis normal, with small meatus; testicles, prostate and seminal vesicles, normal; bladder-wall at base not thickened, but a little tender on the right side; ureters not enlarged; kidneys cannot be palpated; urethra hyperesthetic to such an extent that a satisfactory examination could not be made, even with the thorough application of a ten-per-cent. solution of cocaine hydrochlorate; bladder capacity, ten ounces; contact sensibility, normal.

An effort was made to control the bleeding, which was supposed to be vesical, by injecting two ounces of a one-per-cent. solution of sodium chlorate. This was repeated a number of times on the 7th and 8th of October, but proved useless, and, I may say in passing, that although the local use of this remedy is highly recommended by some for this purpose, I have not found it to possess any value.

On October 9th, under chloroform anesthesia, he was cystoscoped. The image of the vault and those of the right and left segments were entirely normal. Blood could be seen issuing from the right ureter, and a bright scarlet band of blood-clot could be seen waving from its mouth. Clear urine came from the left ureter. Lying close to the neck of the bladder, a reddish mass, presumably a blood-clot, could be seen. The mucous membrane around the internal urethral orifice was intensely congested.

My colleagues, his physician and the consulting surgeon, believed that the hemorrhage must surely come from the bladder and that there must be a tumor. Like many others, they had but little faith in cystoscopy, and advised sectio-alta, to show that there could be no mistake about the source of the hemorrhage. This was done. A careful inspection of the inside of the bladder, by reflected electric light, gave the same results obtained by the cystoscope. The red mass in the bottom of the bladder was a blood-clot, and the hemorrhage came entirely from the right ureter.

On account of the great urethral hyperesthesia and the congestion about its internal orifice, the internal and external sphincters and the prostatic urethra were thoroughly stretched by uterine dilators. The meatus was cut and the phallic, bulbous and membranous urethra dilated rapidly with sounds to its utmost capacity.

Free hemorrhage followed the stretching of the bladder-neck. This was checked by hot

water. The bladder was closed by silkwormgut sutures passed through the skin, the abdominal muscles, and the bladder, including the mucous membrane. The space of Retzius was shut off entirely by attaching the anterior bladder-wall to the transversalis fascia, and the insertion of the recti muscles by buried catgut sutures. This closed the bladder tightly around the De Pezzer suprapubic drainage tube. Two quarts of normal salt solution were given in the chest by hypodermoclysis.

On October 22d the kidney was removed through the incision described by Abbe (*Annals of Surgery*, 1897), and by Mayo Robson (*Lancet*, May 14, 1898). The peritoneum was easily drawn to the left; the ureter rolling up with and upon it, was slightly larger than normal. It was examined carefully from the pelvic brim to the kidney without our finding any trace of neoplasm, stone or ulcer. When the kidney was pulled down slightly, blood could be seen coming out of its pelvis and passing down the ureter in interrupted spurts. This would clot about half-way down and the clots could be squeezed toward the bladder, but almost immediately their place would be taken by others. The kidney was loosened from its fatty capsule, a soft-rubber ligature drawn gently around the blood-vessels, and a free incision carefully made with a thin section knife upon its convex side and through its full length. As the kidney was not indurated, but was a little softer than normal and did not fluctuate when pressed upon, I did not expect to find cancer, sarcoma, or a tuberculous condition; but I did think I would surely find a papilloma in the pelvis or one of the calices. Greatly to my astonishment there was only a general purpuric condition. I would have sewed it up had the patient been entirely under my control, but his weakness was so great, and the macroscopic appearance of the kidney so degenerated, that we determined to remove it.

Two quarts of normal salt solution were used intradermically during the operation and he received four ounces by the rectum every three hours for the first three days; pain and heart's strength being controlled in the usual manner.

His general condition was so bad and the oozing from the wound so profuse that I was obliged to pack the greater part of it, which greatly retarded his final recovery.

Immediately after the operation, the left kidney commenced to secrete clear and acid urine freely. The De Pezzer tube, which had never leaked, was retained purposely in the bladder to run as a tell-tale, and to afford a method of urination, comfortable and free from strain, for the first few days. It was removed on October 26th, and its track closed tightly in twenty-four hours.

His stomach being irritable, he was given, as nourishment, hot milk with Vichy (Celestin's), for the first four days, when some bovinine was gradually added.

The last of the packing was removed on October 29th. For several days he complained of colicky pains in the neighborhood of the cecum, the secretions of the wound had a fecal odor and contained the bacillus coli. There was much pain for a week, but this was controlled very well by the free application of orthoform. A solution of lactate of silver, 1-3,000, in distilled water, was used to irrigate the wound twice daily; this soon removed the odor.

On November 4th I had an alarming experience with him. The urine, which had been freely secreted since the operation, became very scant, high colored, and contained some albumin and much bile pigment. His temperature rose to 101.3° F. and his pulse to 120. He complained of much pain over the remaining kidney. He was given three grains of calomel, by the mouth, and a intradermic injection of three pints of normal salt solution. In a few hours afterward the secretion of urine became profuse, the pain disappeared, and the next day he was all right. He was sent to his home at Santa Barbara on November 15th, with the wound entirely healed.

I have employed this Abbe-Robson incision three times for nephrectomy where necessity existed for the careful examination of the ureter, and, while I like the exploratory freedom which it gives, I cannot commend it. The muscular fibers are apt to be torn across in the process of retraction or in separating them.

I have satisfied myself of this by experimenting upon the cadaver, and the claim that it is a practically bloodless operation has not been in my experience substantiated. I prefer the clean cut, beginning in the front of the quadratus muscle, half-way between the crest of the ilium and the twelfth rib, and extending obliquely, downward and forward above the anterior superior spinous process of the ilium to the semilunar line, which may be found illustrated on page 453, Vol. I., Operative Gynecology, Kelly. This affords the same freedom for the examination of the kidneys and ureter; the same advantage of a prone position; is not any more bloody than the other operation, and gives a wound surface to my mind less liable to infection, and, I know from experience, without practically any liability to subsequent hernia.

Sections taken from the cortical and medullary portions of this kidney were examined by our pathologist, Prof. Stanley Black. He reported that there was not sufficient change anywhere observable to account for the profuse leaking of blood; that without the history of great and long-continued mononephrous hemorrhage he would regard the sections as not those of a diseased kidney. Macroscopically, the kidney when removed from its bed was intensely purple, bled profusely on section, and continued to bleed, seemed soft and degenerated, and as the hemorrhage had been so profuse, and so weakening and depressing over a long period, and the blood continued to well out of the cut surface longer than is usual after section, it was deemed wise by my colleagues and myself to do a nephrectomy in place of the nephrotomy which one would

naturally like to try where malignant growth was found to be absent, and the hemorrhage due to an undiscoverable cause.

No purulent focus was found in this kidney, either before or after its removal. The pus present in the urine undoubtedly had its origin in the subacute inflammatory condition of the posterior urethra, which may have had a reflex connection with the renal hemorrhage. The urethral hyperesthesia disappeared entirely after the overstretching of the whole canal at the time of the suprapubic section; full-sized instruments can be passed easily, without pain or spasm.

At the time of the publication of this article the individual is in excellent health, and conducts, successfully, a large mercantile business.

MEDICAL PROGRESS.

Unusual Signs of Aneurism.—The classical symptoms of aneurism are five in number, namely, tumor, thrill, expansive pulsation, bruit and shock, and yet any one or all of these signs may be absent. Besides these there are many well-known symptoms and signs resulting from pressure of the aneurism upon surrounding organs. M. E. Fitch (*Med. Times,* Nov., 1901) describes several signs of aneurism of the aorta which are rather unfrequently observed, but are of certain value when the more typical signs are wanting. Drummond's sign is elicited by placing the stethoscope over the manubrium. The patient is then ordered to take a full inspiration, allowing the air to escape slowly through one nostril. A peculiar interruption of the breath sound is given to the column of air by the aneurism. Cardarelli's sign of lateral movement of the larynx is similar to that of tracheal tug and closely resembles it. Ewart claims that slight degrees of tracheal tug may be present in normal persons. Scheele's sign is a dangerous one, as shown by the fact that two out of three cases upon whom it was tried died from internal rupture soon after submission to the treatment. He discovered that by pressure upon both crural arteries at the same time a severe pain would be produced in the aneurismal region with the disappearance for the time of the cystolic bruit. Perez's sign is a creaking sound heard over the sternum in cases of anterior mediastinitis when the patient raises and lowers the arm from the shoulder.

Antityphoid Inoculation.—As the years go by medicine is claiming for itself greater exactness as a science, and perhaps in no other field more than in serumtherapy. One of the last additions to this means of treatment is that of antityphoid serum or vaccine, as it is most unscientifically called. A. E. Wright (*Lancet,* Oct. 26, 1901) gives a most important contribution to this subject concerning observations in the Richmond Asylum, Dublin, an institution for the insane. After excluding all the patients above fifty-five years of age as insusceptible to the disease, the total number of those susceptible to the disease at the date on which the inoculations were made is fixed at 655, 541 being insane inmates, 114 nurses, 511 of the former having been inoculated, of the latter none. The number of cases occurring in the uninoculated and inoculated, respectively, during an interval of twenty-four days between the completion of the inoculating and the last case of the disease to develop is as follows: Uninoculated, 114 persons exposed, 5 stricken, no death; inoculated, 504 exposed, none stricken. The comparative incidence of typhoid fever in the inoculated and uninoculated calculated upon the average strength of each group during the period intervening between the commencement of the inoculation and the termination of the epidemic is as follows: Uninoculated, average strength 298, number of cases 30, number of deaths 4, percentage of cases 10.1, percentage of deaths 1.3; inoculated, average strength 339, number of cases 5, number of deaths 1, percentage of cases 1.5, and the percentage of deaths 0.3. While antityphoid serumtherapy is still in its infancy, no one can with reason doubt that the days of deadly typhoid-fever epidemics are over.

Intravenous Medication.—It often happens that rapid action of drugs is necessary to save patients from death. For this purpose G. Baccelli (*Klin. therap. Woch.,* Nov. 10, 1901) recommends the introduction of remedies directly into the veins. It is especially in the severe forms of pernicious malaria where muriate of quinine thus given has accomplished wonderful results. In the grave forms of syphilis there need be no hesitancy about injecting sublimate, as the albuminate of mercury formed is readily soluble in the excess of albumin present. The occurrence of thrombi, edema and perivascular hemorrhages is due to faulty technic. That the action of the mercury is prompt can be seen by the salivation which begins almost at once after injecting. Recently the author has used sublimate intravenously with astonishing results in cattle for foot and mouth disease.

Tuberculosis of Cervical and Bronchial Lymphatic Glands.—Whether scrofula is always caused by or associated with the bacillus tuberculosis has not been as yet definitely determined. While by some it has been ascribed exclusively to this organism others have thought that it might arise through the agency of other microbes and that in certain cases tuberculosis might subsequently supervene. Hugh Walsham (*Jour. Path. and Bac.,* Nov., 1901) considers this subject under the following heads: (1) Is the tubercle bacillus or its involuted forms always found in scrofulous glands? (2) What phases does the bacillus pass through in these glands? (3) What are the histological changes produced by these bacilli in such glands? He examined postmortem the cervical and bronchial glands in twenty-seven consecutive cases of pulmonary tuberculosis. These were chosen in preference to such glands removed during life, because of the suppurative changes generally

present in the latter. In all cases examined the bacillus tuberculosis was found. In five the gland substance proper was changed into a caseous mass and hence was typically scrofulous. He believes, therefore, that so-called scrofulous glands are really tuberculous in nature. Many other varieties of microbes were also found in these glands, but the changes produced are not due to such, as they are but seldom found in the gland substance proper, chiefly being present in the peripheral lymph sinuses. Much variation in the morphology of the tubercle bacillus present was observed. Greatly beaded, budding and branching forms were frequently observed. Schrön's capsules were also present. The first histological change produced in the gland substance proper is the proliferation of the adenoid reticulum with a disappearance of the lymphoid cells. The hyperplasia present is distinguished by the transformation of normal gland tissue into large-celled tissue. Pigmentation is frequently observed, as well as lardaceous change. It is impossible to form an opinion as to whether a given lymphatic gland is tuberculous by naked eye appearances. In all cases serial sections should be made. It is still an open question whether or not the lung can become infected by the gradual extension downward of the bacilli in the lymph channels. In those cases in which the tuberculous changes in the cervical glands are further advanced than in the bronchial it is probable that the lung infection has occurred in this manner. In many such cases the tonsil is the portal of entry. As a rule, however, the infecting organisms are conveyed to the lung through the inhalation passages.

Multiple Sclerosis.—Three cases are recorded by R. v. JACKSCH (*Wien. kl. Rund.*, Oct. 9, 1901) which, according to the general description of the disease, must be classified among multiple sclerosis, yet which presented certain variations which place them in a separate class. The typical symptoms—nystagmus, tremor and changes in the optic papilla—were absent, or present only transiently while inability to go backward and Romberg's symptoms were present. In all three the etiology was the same: The patients were employed in a chemical factory where they were obliged to expose the lower half of their bodies to heat, while the upper was constantly subjected to draughts, so that trauma of a thermal nature must be held responsible.

A New Surgical Position—Access to the diaphragm for surgical operations within the abdomen is especially difficult, because it is almost impossible to get the patient into such an attitude as will keep the parts exposed to work with the least interruption. G. KELLING (*Centralbl. f. Chir.*, Oct. 19, 1901) illustrates what appears to be a very good solution of this difficulty so far as attitude alone can surmount it. The patient in dorsal decubitus is brought to the end of the table so that his lower extremities, pelvis and most of his lumbar spine hang over this end; the feet are supported on a cushion. Slipping is prevented by straps over the shoulders in the usual way, and about the thighs at the groin; the former are to be attached to the other end of the table, the latter to the leg-pieces which hang vertically downward. A screen is erected on a half circle of hoop-iron which passes from side to side just under the arm-pits and supports a sterile towel or sheet and shuts off all possibility of the patients coughing or vomiting into the wound. The abdomen is then opened according to the indications of the disease, and the position assisted by gravity carries most of the organs downward toward the pelvis. In general terms the position appears to be the reverse of the Trendelenburg position. The author of it claims much in its favor.

Parametritis Posterior.—Pelvic inflammations in woman are all important to her as the patient and to us as surgeons with a view of what we shall do for them. P. BROSE (*Zeitschr. f. Geburtsch. u. Gynäk.*, B. 46. H. 1) sums up his latest observations on the subject as follows: Parametritis posterior, according to Schultze, is an affliction of the connective tissues and not of the peritoneum. Parametritis posterior and the parametritis atrophica circumscripta of Freund are the same processes. Parametritis posterior often appears with diseases of the peritoneum, tubes and ovaries, and also not uncommonly with parametritis atrophica circumscripta of other parts of the connective tissue of the pelvis For the cure of parametritis posterior which has resisted all other means, ventrofixation, even if the uterus is anteflexed, is a most successful procedure. When the uterus is retroflexed and bound down by inflammation or not complicated by inflammation, ventrofixation has precedence over all other means of treatment.

Pyloric Stenosis After Poisoning.—A case of pyloric stenosis, which followed the ingestion of a large amount of crude muriatic acid is reported by A. HAMMERSCHLAG (*Wiener kl. Rund.*, Oct. 9, 1901). A gastro-enterostomy, during the performance of which a deep constriction at the pylorus was found, completely cured the patient. Cases where the chief effects of the poison manifest themselves upon the pylorus are not very common and are difficult to explain. It is probable that the coating of mucus which is found, especially in drinkers and smokers, offers a certain protection to the esophagus and fundus of the stomach and to some degree neutralizes the acid. If the stomach is distended, the greater curvature is generally first affected by the corrosive fluid; if, on the other hand, it is empty, the entire gastric mucous membrane is liable to be destroyed unless there is mucus present to protect, when the fundus will pass the fluid on to the pylorus. Where the gastric glands are destroyed and the pylorus is narrowed there will be, as in this case, a high percentage of lactic acid present in the gastric contents.

Changes in Blood and Marrow in Chronic Arsenical Poisoning.—Notwithstanding the extensive literature concerning arsenical poison-

ing, but little is to be found therein with respect to the changes produced in the anatomical features of the blood. A comparative study of these changes and the degree of cutaneous pigmentation present throws light upon the relation of hemoglobin to the pigment of the skin. Different views exist upon this subject, some claiming that melanin is derived from hemoglobin while others maintain the controverse. J. C. MUIR (*Jour. Path. and Bac.*, Nov., 1901) reports the study along these lines of forty-eight cases of chronic arsenical poisoning. Of these nine were also examined postmortem and the marrow changes observed. In the blood-examinations the hemoglobin estimations were obtained by means of Fleischl's instrument; the red and white blood-cells were counted with Gower's hemacytometer; the dried films were fixed with alcohol and ether and stained with hematoxylin and eosin; in a few cases, however, Ehrlich's tri-acid stain was used. The bone-marrow was prepared in films and similarly stained. The blood of arsenical cases having deep cutaneous pigmentation is decidedly richer in red cells and hemoglobin than that of slightly or non-pigmental cases. This disproves the almost universally-accepted hypothesis that the pigmentation is due to destruction of the hemoglobin or red blood-cells and is evidence for thinking that the melanin of the skin is an important element in the production of hemoglobin. In human beings arsenic causes a decided erythroblastic reaction in the marrow of the long bones. A slighter but distinct leucoblastic reaction also occurs, which, however, may be in part or wholly due to an accompanying tuberculosis. The erythroblastic function of the marrow of the long bones is more easily stimulated in the presence of a large store of cutaneous melanin.

Determination of Organic Acid in Urine.—To determine the amount of organic acid present in urine the following method is given by F. OBERMAYER (*Wiener. kl. Rund.*, Oct. 9, 1901): Forty c.c. of acid urine are precipitated with chloride of barium; 25 c.c of the filtrate are diluted with 15 c.c. of distilled water and 6-7 drops of an alcoholic solution of dimethylamidoazobenzol added. Filtration is now carried on with decinormal hydrochloric acid until there is a decided change of color. The amount of the acid used will be an indicator of the amount of organic acids present in 20 c.c. of urine. Creatinin and albumin must be removed from the urine before the titration is begun.

Diagnosis of Tuberculous Meningitis.—The introduction of the lumbar puncture has made it possible to examine directly the exuded fluid and various methods are in current use to prove whether or not the fluid is tuberculous. R. BREUER (*Wiener klin. Rund.*, Oct. 9, 1901) briefly reviews these. A positive result after injecting the aspirated fluid into guinea-pigs takes too long to be of value. It has been pointed out that cerebrospinal fluid forms an excellent culture medium for the tubercle bacillus, but to set the fluid aside in the incubator and await a multiplication of the germs would also demand patience. The agglutination test is of no value, and the finding of a preponderance of mononuclear leucocytes is not always conclusive for tuberculosis. A direct examination of the stained sediment of the fluid is generally negative, but when done properly has proved positive in the 17 cases examined by the author. The fluid must be collected in test-tubes each containing 4-5 c.c. and these set aside, care being taken not to shake them. After 3-6 hours a very fine coagulum, containing the cellular elements with the bacteria, forms, while the fluid itself will be absolutely clear. An examination of the coagulum will almost always be crowned with success. In a second article in the same number, J. DONATH discusses the serodiagnosis of tuberculous meningitis. Five to fifteen drops of a specially-prepared, homogeneous culture were mixed with one drop of cerebrospinal fluid. The results were noted after 8-24 hours. Of four cases in adults there was a negative reaction in one, a partial one with a dilution 1:5 twice and a complete one with a dilution 1:5 once. In two cases in children the reaction turned out negative. The clinical value of the method according to the author is slight.

Dangers of Internal Urethrotomy.—The choice between the internal and external method of doing this operation is always difficult with the greater dangers on the side of the internal, says LAUWERS (*Jour. de Chir. et Annal. de la Soc. Belge de Chir.*, Sept. and Oct., 1901) and further gives the following points: As soon as it is impossible to pass a retention catheter or as soon as fever persists in spite of its presence, it is necessary to watch the patient most carefully and to be ready in the event of the appearance of serious symptoms to perform external urethrotomy or subpubic cystostomy. He has performed external operations for checking symptoms of infection of grave degree after an internal operation and is persuaded that the life of his patient was saved in consequence of it. The subpubic cystostomy certainly secures direct and free drainage, but presents the great difficulty of filling the wound in the urethra from above with the poisonous contents of the infected bladder. He therefore claims that the simple external urethrotomy shows better surgical judgment.

Nephrolithiasis and Spinal Disease.—The relation between renal stones and affections of the spinal cord are summed up by H. SCHLESINGER (*Wien. klin. Rund.*, Oct. 9, 1901) as follows: (1) Renal stones have been observed rather frequently in traumatic destruction of the spinal cord and syringomyelia; much more rarely in tumors; (2) the symptoms of nephrolithiasis follow after months or years; (3) the stones are generally phosphatic, less often uratic; (4) cystopyelitis is generally present with the phosphatic stones; (5) the spinal affection seems to favor the formation of stones directly or indirectly.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

NEW DISCOVERIES IN INTESTINAL PERISTALSIS.

PHYSIOLOGICAL research of much more than ordinary interest to medical practitioners was reported by Dr. Walter B. Cannon before the Boston Society of the Medical Sciences at its last meeting, November 19, 1901. The addition to our knowledge thus made is likely to have far-reaching effects in clearing up a number of points heretofore obscure.

Dr. Cannon is already well known to students of physiology for his interesting observations on the movements of the cat's stomach during digestion, these being revealed clearly by the Roentgen rays when the food is mixed with a small proportion of bismuth. The present research is a logical continuation of the former, but in many respects of more practical importance. It considers in a similar way the movements of the intestine, and reveals these adequately for the first time, and therefore by almost certain analogy those of the gut of all mammals, including man. The events described here were proven not only by negatives taken directly with the rays passing through the animal but by actual demonstration on the cat.

Intestinal peristalsis as revealed by our new light consists of "recurrent segmentation" combined with advancing movements. This discovery of recurrent segmentation is new and is obviously the most interesting mechanical process of the small intestine. A string-like mass of chyme, four or five centimeters long, is seen lying quietly in one of the intestinal loops. Suddenly an undefined activity appears in the mass and a moment later constrictions at very regular intervals along the length of the food mass have cut it into little bits. In two seconds (on the average) constrictions around the centers of each of these little portions have divided each of them into halves, and have thus united the latter into similar masses occupying the spaces first mentioned. Thus the alternate dividing process goes on for half an hour or more in each mass of chyme. These regularly alternating constrictions occur in the cat twenty-eight or thirty times a minute, so that a given length of digesting food may be chopped apart and rejoined at least a thousand times before it passes along into another loop.

Here we have an explanation for the first time how the food is brought into contact with the gut-wall with intimacy adequate to the minute and complicated functions of mixture with the juices and of absorption. So, too, is explained at once what is the motive power of absorption by villus and by capillary and the force which so powerfully aids the circulation of blood in the gut.

The peristalsis in the large intestine is found by actual sight to be from the left end of the transverse colon to the ileocecal valve—antiperistalsis. The valve was found to be perfectly competent for the normal contents of the gut, for by no manipulation could they be forced backward into the ileum. On the other hand, liquid nutrient enemata readily passed upward and throughout the small intestine in even a quarter of an hour. From these facts one understands fully, again for the first time, the function of the ileocecal valve, for, the peristalsis of the large intestine being backward were it not there, harmful admixture would take place. Again, one can now realize the physiology of nutrient enemata, and that they are absorbed probably in the small intestine rather than in the large. Perhaps, too, the cause of certain common cases of appendicitis is revealed, the possibility now appearing that violently toxic substances from the rectum may be passed backward by the antiperistalsis and into even a normally closed appendix.

As was found to obtain, also, in case of the stomach, vexing emotions instantly stop all movements of the intestines, thus explaining many an experienced attack of functional indigestion.

We understand that the complete paper giving the details of these interesting new facts will appear in the *American Journal of Physiology* early in 1902. We are glad to have the opportunity of advancing these notes on this interesting and productive piece of work. We hope that these same observations will soon be made on the human subject so as to further this promising line of inquiry.

HOME-TREATMENT OF TUBERCULOSIS.

IT IS the custom to say that "end-of-the-summer colds hang on." There is perhaps some truth in the tradition, but by physicians it is generally understood that most of the presumably persistent summer and autumn colds are really pulmonary tuberculous processes that have been lighted up to a noticeable degree by the overexertion of vacation or the exhaustion incident to hot weather. Cases of tuberculosis are perhaps much more prominent in ordinary practice during the fall than at any other season of the year. The constantly-recurring problem for the physician is, How shall these cases be treated when first recognized? Because of the meeting of the Tuberculosis Congress in London during July, and the medical interest in the subject thus awakened, a number of practical points have recently been brought into prominence in the medical journals.

The important phase of the question of treatment that first presents itself is, Shall the patient be sent away from home? The affirmative answers to this question are by no means so unanimous as they used to be. Change of climate is no specific for tuberculosis. Any particular climate would seem to be no better than any other except inasmuch as it may allow of patients being more continually out-of-doors. For this, uniformly-mild, warm weather is not absolutely essential. On the contrary, for most people brought up in a changeable climate and accustomed to the bracing tonic of yearly wintry recurrences, a continuously-warm climate may prove so relaxing as to be positively harmful. Many a healthy person compelled for some reason to miss the northern winter to which he has been accustomed all his life may feel distinctly less active during the succeeding year.

It is probable that the enervating effect of a hot summer has much more to do with the development of the frequent acute exacerbations of pulmonary tuberculosis seen in the fall than the supposed deleterious effects of the changeable weather. Certainly the conditions found in these cases, as a rule, are not the results of recent pathological processes, but have been manifestly preparing for weeks, if not months. Tuberculosis is not due to cold and its progress, contrary to popular belief, we know is not fostered by cold weather. Actual experience has shown that for most cases of incipient tuberculosis a cold but dry climate is distinctly more favorable than a warm one, especially if the latter be also more or less moist. When Dr. Trudeau first proposed the Adirondack region for consumptives he was considered by many medical men to be riding a dangerous hobby, but time has amply shown the wisdom of his suggestion.

The cold of our city climate, then, is no contra-indication to its wholesomeness for consumptives. There are so many personal inconveniences and discomforts in addition to the serious discouragement attached to removal of patients to a distance, that their home-treatment becomes an alluring temptation. If there is reasonable assurance that directions will be followed it seems not only justifiable but advisable to try home-treatment for awhile. The index of failure in treatment is continuance of loss of weight. If patients gain in weight there is every assurance of their progressive improvement. Certain cases present actual contra-indications to removal to elevated regions. As Prof. Burney Yeo said at the Tuberculosis Congress, patients with laryngeal complications are never benefited by a mountain climate, while, if emphysema is present as well as tuberculosis, elevation does harm rather than good. Where intestinal complications or any renal disease exist, they are positive contra-indications. A climate having very wide diurnal variations is ideally bracing for consumptive patients generally, but leads to frequent disturbances of circulation that prove irritating to intestinal or kidney disorders for which the maintenance of a continuous equilibrium of circulation is the indication.

Some of the London experience with absolute open-air treatment in the home climate is suggestive. Dr. Hector Mackenzie in the Tuberculosis number of the *London Practitioner* (July, 1901) relates the details and results of cases kept night and day on an open hospital balcony. One

of his patients had suffered severely from that always-trying symptom, repeated hemoptysis. Another had suffered tortures from tuberculous pleurisy. In this latter affection, the continuous exposure of the patient to all the disagreeable vicissitudes of the London spring without harm is especially noteworthy. In the hemoptysic patient, improvement did not begin for a month, but then was rapid and satisfactory. The patient gained twenty-eight pounds in a few months. The case of pleurisy began to improve after the fourth day. Despite cold nights the patient did not complain of discomfort and slept well. The gain in weight soon restored her to good health and her painful pleurisy was felt no more.

In a word, recent contributions to the literature of tuberculosis point to the fact that the successful home-treatment of tuberculosis may be entirely feasible in cases where from extreme sensitiveness to cold or marked tendency to catarrh or other physical contra-indications in lungs, or digestive tract, or kidneys, a sojourn in elevated regions is unsuitable. If there be added the number of patients in whom the lack of means or the danger of depression from nostalgia makes removal especially difficult and problematic in its effect, it will be seen that there is a large field for the development and employment of properly-managed home-treatment for tuberculosis.

METABOLISM IN DIABETIC COMA.

THE acid-intoxication theory of diabetic coma is of comparatively recent origin. The high grade of urine acidity in diabetes, together with the fact that the same is due to the presence of inorganic acids, having been established in 1884, it would seem but a step to the comprehension that such must signify an intense acidosis of the system which in turn must stand in direct causative relation to the symtomatology of the disease. It was not, however, until 1899, largely through the work of Magnus-Levy and Herter, that the definite relation between acidosis and diabetic coma was fully appreciated. Since that time the acid-intoxication theory of diabetic coma has steadily added to the number of its adherents until to-day it finds practically universal acceptance. (E. P. Joslin, *Journal of Medical Research,* Nov., 1901.)

Practical therapeutic deductions have not been wanting, and it has been abundantly proven that the administration of a sufficient amount of alkali is, in many cases, able to overcome the acidosis, temporarily at least, thus ameliorating the condition and prolonging, if not saving life. Although the work hitherto done along these lines has laid the foundation for an accurate understanding of the metabolic changes present, there are many points which remain obscure. In most instances the immediate pre-coma period is characterized by the presence of large amounts of inorganic acids in the urine. Such, however, is not always the case. Exceptionally these acids are not demonstrable until twenty-four hours preceding coma. In such cases the explanation of the non-presence of such acids is not entirely clear. It is known, however, that the oxidation of inorganic acids requires the simultaneous oxidation of carbohydrates. In accordance with this fact inorganic acids appear in the urine of healthy individuals when carbohydrate food is entirely withdrawn; they however disappear when a small amount of such food is taken. It seems probable, therefore, that in the exceptional cases mentioned the body is able to oxidize a certain amount of the carbohydrates present and that coincidently these acids are likewise oxidized in the system and do not appear in the urine. This view does not, however, explain all cases.

Of late much stress has been laid upon the prognostic value of the frequent determination of the amount of inorganic acid present in the urine. It should be remembered that the presence of these acids in large amounts is highly significant of impending coma, but that unfortunately the converse does not hold true. In other words their absence does not uniformly warrant a favorable prognosis. The most ready and a sufficiently accurate manner of ascertaining the degree of acidosis present is by the administration of sodium bicarbonate. In healthy individuals the exhibition of ten to fifteen grams of this substance gives rise to a neutral or alkaline urine. In diabetics one to two hundred grams are often so required. The estimation of the amount of ammonia present in the urine is also a measure of its degree of acidity, but is not a safe guide when alkali or sodium bicarbonate is being taken.

During coma, in addition to the endeavor to neutralize the acids present in the system, every effort should be made to favor their excretion. It has been found that the amount of urine and the amount of acid excreted are directly proportionate to each other. We have thus a point of immense practical value and one of the cardinal

factors in the successful treatment of diabetic coma. Every effort should be made to produce abundant diuresis.

It is evident that in diabetic coma normal metabolism is markedly perverted. Certain groups of substances which once served as nutrients are no longer of avail, but are changed into products which are not oxidized and hence appear in the urine. We are at present acquainted with one of these groups—the inorganic acids. Their presence in large amounts in the body is harmful, not because of any specificity, but because of the degree of acidity produced. Nature endeavors to overcome this acidity by the increased production of alkali and increased excretion. The assistance of Nature in its endeavors forms the keynote of the proper treatment of this condition.

REPORT OF THE ST. LOUIS TETANUS COMMISSION.

THE special report of Drs. B. Meade Bolton, C. Fisch and E. C. Walden, who were appointed a special committee to investigate the occurrence of tetanus from the use of the diphtheria antitoxin in the city of St. Louis, is to hand in the *St. Louis Medical Review* of November 23d.

The conclusions reached are in substantial accord with the report made by our special correspondent given in the issue of November 9th, save that it appears that some serum prepared on September 30th was distributed and, moreover, that serum prepared at that time was bottled as serum prepared on August 24th. This accounted for the contradictions of dates in the early reports.

The results of this investigation may be summarized as follows: The diphtheria antitoxin prepared by the Health Department of the City of St. Louis, and dated September 30th, and some of the serum dated August 24th, was the cause of the recent deaths from tetanus in the cases where this tetanus was used. This antitoxin was sterile, but contained the toxin of the tetanus bacillus in considerable amount.

There were two different sera issued under the date of August 24th, one portion not containing the tetanus toxin and characterized by other properties, while the other contained the tetanus and was identical with the serum bearing the date of September 30th.

The most important result arrived at is the positive demonstration that the toxic serum dated August 24th and that dated September 30th are identical. From this it is concluded that the serum of September 30th was issued without having been tested by the proper methods, and that a part of it was filled into bottles bearing the date of August 24th, and were furnished with labels having previously been stamped with this date. The Committee was justified in drawing this conclusion from two observations. First, that the serum of September 30th was issued before there was time to have performed the simple tests necessary to determine the antitoxic potency of the serum. Second, in the same way, serum dated October 23d came into the possession of the Committee on November 1st. This serum had been issued to physicians by the Health Department, and by them returned to the coroner. It is obvious from this that no animal experiments could have been made with this antitoxin. As this was the case with the serum of October 23d, it is the natural inference that the serum of September 30th was issued in the same way.

It is denied that there was any possibility of latent tetanus having existed in the horse "Jim" from August 24th to September 30th, as no well-authenticated cases have been reported in which the incubation period extended over seven days, in experiments directed to test this point. The period of incubation cannot be determined from clinical observation, from the nature of the case.

It therefore follows from this that the serum drawn on August 24th was free from tetanus, but that the serum of September 30th was drawn during the period of incubation, and had it been tested upon animals it must necessarily have revealed its toxic properties.

From the foregoing facts the Committee is forced to conclude that the diphtheria antitoxin prepared by the City Health Department has been issued before it was possible to have obtained results from the absolutely necessary tests. Had these tests been performed, the results upon animals would have been such that the serum would not have been dispensed, and the cases of tetanus forming the basis of this report could not have resulted.

Further comment on this report is needless. The error was one of human fallibility and is freely exposed. No effort is made by the authorities to hide the unpleasant fact that there was carelessness in the manufacture of this particular lot of serum, and, much as the accident is to be deplored, the experience will not be without its profit for those who may come after.

ECHOES AND NEWS.

NEW YORK.

New Columbia Trustee.—Dr. E. L. Trudeau, P. & S., 1871, was elected trustee of Columbia University to fill the vacancy caused by the death of Dr. W. H. Draper.

Colored Hospital.—The managers of the Colored Hospital held the Graduating Exercises of the Training School for Nurses of the class of 1901 at the Academy of Medicine, Friday evening, December 6th. Dr. T. Gaillard Thomas delivered the address.

St. Mary's Hospital, Brooklyn.—The annual promenade concert and reception in aid of St. Mary's Hospital was held on Tuesday evening, the 26th ult., at the Pouch Mansion. There was a large attendance, and a considerable sum was raised. The proceeds will be applied to the relief of the sick and crippled children in St. Mary's wards.

Consumptive Children Excluded.—There is much indignation among the parents of children attending Public School No. 108 in Brooklyn, regarding a little girl said to be in the last stages of consumption. The parents desire that the sick child be excluded from school privileges lest their children become affected with the disease. The Board of Education when notified referred the case to the Board of Health, saying that the latter board had entire responsibility for the health of school children. The case, however, at this writing had not yet been reported to the Sanitary Bureau.

New York Academy of Medicine.—On Monday, December 9th, the Section on Surgery will meet. Dr. Lilienthal will present a patient recovered after an operation for pancreatitis and Dr. Erdmann one recovered after operation for intussusception. Dr. C. N. Dowd will read a paper on Gangrenous Intussusception in a Child of Four Years; Intestinal Resection; Recovery. Dr. George Woolsey will read a paper on Acute Pancreatitis with a Report of Three Cases.

On Wednesday, December 11th, at the meeting of the Section on Otology, Dr. B. A. Randall will present a paper entitled, Some Notes on the Teaching of Otology, with Lantern Slide Demonstrations.

On Thursday, December 12th, papers on Malnutrition will be read before the Section on Pediatrics: Dr. C. G. Kerley, on Syphilis; Dr. F. M. Crandall, on Tuberculosis; Dr. A. Jacobi, on Rachitis; Dr. L. E. LaFetra, on the Importance of a More Thorough Knowledge of the Chemistry and Physiology of Food, and Dr. S. H. Dessau, on the Action of Heat upon Cow's Milk as an Infant Food. Discussion by Drs. W. H. Porter, H. D. Chapin and J. Downing.

Dr. Martha Wollstein is recommended for election as resident fellow of the academy.

Medical Education in New York.—The report of the College Department of the University of the State of New York for the year ending July 31, 1901, will show that, during the nine years in which the medical licensing examinations have been held, 6,349 physicians have been examined, of which number 78 per cent. were licensed. During the last year, in medicine 671 regular candidates, 58 homeopaths and 20 eclectics have been examined. There were no failures in the case of graduates of six of the New York medical schools, and in only two of the New York schools did the percentage of accepted candidates fall below 90. In consequence of the number of requests received psychology will be given in the January, 1902, examination.

Appointment of Dr. Bailey.—Dr. Pearce Bailey was appointed instructor in neurology at Columbia University at the meeting of the Board of Trustees last Monday.

State Medical Society.—The annual meeting of the Medical Society of the State of New York will be held at Albany, New York, Tuesday, January 28, 1902, and will continue for three days. The scientific part of the program is being prepared by the Business Committee, which consists of Dr. Nathan Jacobson, 430 South Salina street, Syracuse; Dr. George R. Fowler, Brooklyn, and William C. Krauss, Buffalo. Members and delegates desiring to read papers will please communicate with the Chairman of this Committee. A rebate will be given by the railroads to members and delegates attending this meeting, but it is necessary in order to obtain this rebate that a certificate be obtained from the ticket agent at the starting-point, which the agent will give for the asking.

Medical Experts Fees.—Corporation Counsel Whalen, in a recent letter, has advised Comptroller Coler not to pay medical experts for services rendered at the request of Commissioners appointed to examine into the mental condition of persons indicted for crime until the power of such commissions to employ such experts shall have been judicially determined. Many claims of such Commissioners have been filed with the Comptroller, and include salaries of Commissioners, salaries of clerks and stenographers, and other expenses, as well as the fees of experts in lunacy.

PHILADELPHIA.

Wills Eye Hospital.—Owing to the veto by Governor Stone of the small appropriation voted this hospital by the State, it may be necessary to cease granting the privileges of that institution to patients from outside the city. The hospital is supported by an income of $19,000 per year and 14,000 persons are treated annually. A sum to finish a partly-completed contagious ward and to purchase $2,000 worth of new instruments must now be taken from the maintenance fund for next year.

Quest for New Municipal Hospital Site.—Dozens of sites have been offered the Committee on City Property, but none has yet been chosen.

It is believed that there is a strong tendency on the part of the city authorities to push the Petty's Island scheme in spite of objections from this city and Camden. The City Solicitor has given the opinion that it is unlawful for the city to take title to and erect a hospital and have full control of the same outside of the county line. This would bar the use of the island in question.

Tetanus Occurring During Vaccination.—Dr. Robert N. Willson read a paper on the above subject at the meeting of the County Medical Society, November 27th. He takes exception to the use of the shield, stating that it is not only of no advantage, but that more than anything else it conduces to tetanus. He uses an aseptic gauze pad, covered with cotton, and a bandage, this dressing being changed twice daily. A covering of lint and zinc oxide is used when the vesicle ceases to discharge. Dr. Willson has treated several cases of tetanus during the recent epidemic and finds that no one remedy is worthy of special confidence, antitoxin and carbolic acid both failing frequently.

Treatment of Tetanus.—Dr. F. A. Packard stated that the only cases of tetanus he had seen recover were those treated by injections of carbolic acid, every case treated by antitoxin having died. Twenty-five grains of the drug may be given in twenty-four hours with no symptoms of poisoning. Whether or not it possesses a specific action against the toxins of tetanus, he is convinced that its use is the one way of curing tetanus if cure be possible. Dr. Packard uses vaccine shields and believes that they do harm only when so tight as to obstruct the circulation of blood or lymph. All the very sore arms under his observation were those on which he had used a gauze dressing, it seeming to act as a mechanical irritant. The shield is to be preferred if it be removed at the end of forty-eight hours.

Relation of Bovine Virus to Tetanus.—Dr. Joseph McFarland discussed this topic. He has been making a special study of the subject of tetanus occurring during vaccination and, although not yet ready to make a full report of his investigations, he deduced some very interesting facts. He has found but five cases occurring during the early years of vaccination, one in 1853 and the remaining four in 1882. With this goes the fact that before 1882 human virus was almost solely employed. Now that bovine virus is almost exclusively used and a large number of cases of tetanus have recently occurred, the connection between glycerinized lymph and tetanus is suggested. Investigations show that in some outbreaks there is a regularity between the use of certain vaccines and the occurrence of tetanus. A careful study also reveals the fact that cases have occurred in bunches, as if a certain batch of vaccine material had been implicated in their production. As before stated, positive conclusions have not yet been reached, but from all the facts observed Dr. McFarland believes that the possibility of infection from virus now employed is not so remote as believed by many physicians.

Smallpox Again Increases.—During the week ending November 30th there were reported 116 new cases of smallpox in this city. This record is surpassed only by the statistics of the smallpox epidemic of 1876. Deaths during the same period numbered 14. The northeastern and northwestern portions of the city are mainly affected. The conservative *Public Ledger* in an editorial, after speaking of the necessity of widespread vaccination, says: "Universal vaccination cannot be secured unless the people are thoroughly aroused to the danger which confronts them. They are not so aroused as yet, because many of them have been lulled into a feeling of false security by the policy of silence that is being pursued by the Board of Health. What is needed in this crisis is the fullest publicity. The number of new cases should be given out daily. It is folly for the Bureau of Health to pursue the policy of silence any longer; it is confronted with the probability of a serious epidemic, and one of the best means of mastering it is to make the public acquainted daily with the exact situation."

Death of Dr. Essig.—Dr. Charles J. Essig died of pneumonia December 2d. Dr. Essig was a graduate of the Philadelphia Dental and of Jefferson Medical Colleges. After serving as instructor in several local dental colleges Dr. Essig organized the Dental Department of the University of Pennsylvania and was for many years its dean.

Water Measles.—A disease known by the above name in the Philippines and supposed to have been brought from those islands has made its appearance in New Jersey and in Stroudsburg, Penn. The eruption is a resemblance of water blisters, which finally burst. The eruption is accompanied by fever.

Report of Camden Board of Health.—The committee to investigate the recent outbreak of tetanus has made a report embodying the following points: Samples of all the makes of vaccine employed in Camden have been tested by the State bacteriologist and found to be entirely free from tetanus germs; the infection in each case of tetanus resulted from neglect on the part of the patient to give their vaccination proper attention; one case of tetanus occurred after a gunshot wound; the tetanus cases in Camden are to be explained upon atmospheric and telluric conditions which have prevailed during the past six weeks, there being dry weather and high winds; vaccination is harmless and should be insisted upon by physicians as an absolutely necessary procedure for the prevention of smallpox.

CHICAGO.

Electro-Medical Society.—This Society has taken steps toward joining hands with the State Board of Health in charging alleged medico-electrical experts with violating the State law which provides that only registered physicians

shall treat disease. The Society seeks to propagate the use of electricity as an aid to medical treatment and the use of the X-ray as a therapeutic agent. People who know nothing of medicine and are not registered physicians, it is said, have been treating serious diseases. It is proposed to stop this and to place the use of electricity and of the X-ray on a strictly professional basis. Officers for the ensuing year were elected as follows: President, Dr. G. G. Burdick; First Vice-president, Dr. A. W. Baer; Second Vice-president, Dr. Emil H. Grubbe; Secretary and Treasurer, Dr. R. H. Street.

Notable Gathering of Scientists.—Prominent scientists from all parts of the United States will attend the midwinter gathering under the auspices of the Field Columbian Museum, the University of Chicago and Northwestern University. The convention will begin December 31st. The meeting was brought about largely through the efforts of Dr. John A. Dorsey, Curator of the Field Museum. Among the societies which will be represented will be the American Naturalist Society, American Society of Morphology, American Physiological Society, Association of American Anatomists, American Psychological Association, Society of American Bacteriologists, and the Anthropological Section of the American Association of Anatomists.

Investigation at Dunning.—Drs. Hugh T. Patrick and Frank Billings are the medical members of the committee appointed by the President of the County Board to investigate the County institutions at Dunning. The committee has already begun its work.

Diphtheria in Evanston.—It is said that this disease is causing some alarm in this suburb. Sixty cases have been reported in the last two months.

Treatment of Pneumonia.—Dr. Edward F. Wells, in his presidential address, at a meeting of the Chicago Society of Internal Medicine, held November 27th, discussed this subject. Among other things he said: "The fact that pneumonia is increasing in prevalence is *prima facie* evidence that prophylactic measures have either not been adopted or have proven unavailing. Pneumonia is caused by the pneumococcus. The pneumococcus will not grow in acid media, and in its growth it produces an acid and an albumose, which in turn probably cause the death of the organism. Its different strains vary in virulency, and somewhat in biological characters. The pneumococcus is present in some part of the upper respiratory passages in a very considerable proportion of healthy persons, and it is probable that pneumonia is ordinarily due to the aspiration and slipping down into the alveoli of some of these ready-at-hand cocci." All discharges from the respiratory passages should be treated in such manner that they cannot gain access in the form of spray or dust to the respirable air. Pneumonic sputum should not be allowed to become dry, but should be burned. The tenacious, clinging expectoration should be carefully removed from the lips, teeth, etc. The mouth, throat and nostrils should be cleansed at proper intervals with an acid solution, followed after a few minutes by an agreeable mildly-alkaline antiseptic solution. With reasonable care along these lines it is probable that the infected person may jeopardize only very slightly the safety of those who come in contact with him. The chief element of danger in pneumonia is from the introduction of the pneumococcal toxins into the fluids of the body. This is one of the most powerful of the bacterial toxins, as may be inferred from the profound chill and raging fever which follow the initial introduction into the system of an infinitesimal quantity of the poison, and this diluted almost beyond conception. That the system becomes less impressionable and more resistant to the toxin as the malady advances is evident from the fact that progressively-increasing quantities of toxins absorbed do not produce correspondingly more pronounced effects. The essayist then discussed capillary paresis, leucocytosis, and antipneumococcic sera. With reference to the latter, he said that animal experimentation with dialyzed toxins, the glycerinated extract of dead and dried bodies of the pneumococcus, the serum from pneumonic patients, and the serum from animals, which have been subjected to long-continued pneumococcal inoculations, have, so far, been inconclusive as to their prophylactic or curative powers, and clinical experience with the various sera which have been placed upon the market has been equally inconclusive. He was free to say, however, that he has witnessed phenomena following the hypodermic injection of such sera which lead him to believe that they are agents of real and beneficent power. In one case the injections were followed by the reappearance in the blood, while the disease was yet at its height, of those harbingers of subsiding toxemia, the eosinophile leucocytes. Analogy leads us to believe that a useful antipneumococcic serum may be produced.

He believes that the employment of oxygen inhalations, begun early, certainly at the very beginning of a slight but steadily-progressive increase in frequency and shallowness of breathing, frequently and freely given, is a useful measure, and is one of the many things which may sometimes save a life which might otherwise be lost. He uses it with strychnine, caffeine, camphor, morphine, etc., each of which agents, properly, employed, is of the greatest value.

Pleurisy with Permanent Pneumonic Induration.—Dr. Robert H. Babcock, at the same meeting, reported four cases of this disease and propounded the query, Are they tuberculous? In these four cases he was impressed by several quite peculiar circumstances. First, the patients did not seem very ill and, judged by the mildness of the pyrexia and other symptoms, their illness seemed to be of a low grade of activity. All but one appeared to have recovered and are now in good health. Second, to judge from the extent and degree of dulness, one would have

expected considerable effusion; yet the insignificant degree of pressure-effects and the result of tapping demonstrated that the exudate was poor in serum and rich in fibrin, and that the degree of dulness and the quality of the respiratory sound at the apex could not be due to pressure or fluid in the lung, since the amount of fluid was in reality small. Third, one patient has since died of pulmonary tuberculosis, and in two of the others the personal and family histories were those of tuberculosis. Fourth, examination of the sputum, when any could be obtained, which was not always the case, failed to reveal tubercle bacilli. It is to be regretted that the serum was not obtained in such a manner as would have possibly thrown light on the nature of the cases had it been injected into animals and subjected to a culture test. He could only conjecture concerning the pathology of these cases, but the only conclusion that seems to explain them is that they were tuberculous. He believes that in three instances at least there had existed a small tuberculous focus at the apex, and that from this focus bacilli were carried by the lymph stream in a reverse direction to the fluid cavity. They there set up a pleuritis which was chiefly fibrinous. From this pleuritic exudate germs were carried to other parts of the lung, and there excited a pneumonic inflammation which was interstitial and tended to fibrosis. In this way the upper lobe, as well as the pleura, was involved in the process, and this combination accounted for the physical signs and subsequent findings after a lapse of many months. Of course, this explanation lacks the verification of postmortem examinations, but the well-known action of tuberculosis makes this explanation reasonable.

Plastic Operation for Shrunken Orbit.—Drs. Henry Gradle and M. Ritter presented a patient in whom a shrunken orbit had been successfully enlarged by plastic operation. The injury was done by molten steel, which destroyed the eyeball and burned the lower lid. Dr. Ritter had enucleated with normal healing. But when the patient returned half a year later to get a glass eye, the orbit was contracted and the inferior cul-de-sac so nearly obliterated that a glass bead 16 by 8 millimeters could scarcely be inserted and could not be retained. A transverse incision was made into the cicatricial tissue from internal to external canthus, and the dissection extended until a normal depth of inferior cul-de-sac seemed established. The wound was lined with Thiersch grafts of epidermis from the arm, which were retained by gauze packing. There was uneventful primary union, without any sloughing. Although the grafts were over an inch in length and nearly three-quarters of an inch wide, the first operation proved inadequate. The same procedure was repeated on the same scale twice at intervals of four weeks, each time with perfect union. The patient now wears an ordinary-sized eye with comfort. Dr. Gradle has previously had equally good results with Thiersch grafts in similar cases of less severity, while trials with Wolfe-Krause flaps in another instance had not given satisfaction.

GENERAL.

Insurance at Giessen University.—Giessen University insures its students against accident, paying $3,000 in case of death. Medical, chemical and veterinary students pay 20 cents a term for insurance; for the others no charge is made.

Woman Physician Appointed in Russia.—Dr. N. Sieber-Schumow has been temporarily appointed to fill the place of the late Professor Nencki as head of the department of Biological Chemistry in the Imperial Institute of Experimental Medicine at St. Petersburg.

Tuberculosis in Cleveland.—An investigation into the health conditions of this city has developed the fact that one out of every fifty inhabitants is suffering from tuberculosis. The investigation was made by the city authorities and Dr. B. G. Hannum. Steps are being taken to prevent the spread of the disease. The ordinance prohibiting spitting in street cars is to be enforced and clubs are being organized by the citizens to aid the authorities.

Suits Follow St. Louis Tetanus Cases.—Seven heads of families whose children died of lockjaw following the administration of antitoxin for diphtheria and four whose children were stricken with tetanus, but recovered, have announced their intention of suing the city for damages. They will base their suit on the Coroner's verdict, which found the city Health Department guilty of negligence in the manufacture and distribution of antitoxin.

British Medical Temperance Association.—A meeting of this Association was held at the London Hospital on November 15th. Professor F. Sims Woodhead presided. Dr. J. J. Ridge, in pointing out the advantage of total abstinence, said that we are all total abstainers from something or other, such as opium; and referred to the statistics furnished by sick benefit and life insurance societies, which proved that the total abstainer from alcoholic beverages had on the average less disease, more rapid recovery, and longer life. A very large number of medical students were present and took part in the discussion.

Plague at Honolulu.—A recent letter from Honolulu gives news of an alleged epidemic of bubonic plague at that port, reports of which have been carefully suppressed by the authorities up to the present time. The disease has made alarming headway among the Asiatics at Honolulu, and preparations are now being made to quarantine the port against the world, the embargo to go into effect next week. Twenty-three cases are positively known to exist, for this many plague patients are now at the Kalihi detention camp. This camp is guarded night and day. Fourteen of the known cases are Japanese and nine are Chinese. The Honolulu papers are not allowed to print any particulars concerning the plague.

Health Resort Problem.—The problem of housing and caring for the consumptives and

other invalids by whom San Antonio, Texas, is overrun is becoming serious. With the approach of cold weather in the North the influx of the sick has continued until boarding houses, hotels and the hospitals are filled to overflowing, and still the streams keep coming. If the invalids had money new hotels and boarding houses would be built, but the majority of San Antonio's transient population is composed of patients of small means or none. A movement is on foot to raise a fund to build a large free hospital to supplement the work of the City Hospital.

Lead-Poisoning in the English Potteries.—The new special rules proposed by the British Home Office for protecting the lives and health of the pottery-workers have met with a varying fate in arbitration. Manufacturers remain, for the present at least, absolutely free from official interference so far as process is concerned; the use of raw lead is still permitted them, and the percentage of soluble lead yielded by their glazes is a matter for their own consideration and consciences. The special rules of 1898 first introduced the compulsory use of fans for the removal of poisonous dust; workers were compelled to wear overalls and the manufacturers were compelled to provide better washing facilities. Since then there has been a remarkable diminution in the number of cases of lead-poisoning.

Another Open-Air Colony for Tuberculosis.—A sanatorium for the treatment of tuberculosis established near Plymouth, Mass., goes even further than the colony of consumptives living in tents near Denver, to which the MEDICAL NEWS referred last week. The patients at the Plymouth colony live in little shacks about twelve feet square, of which three sides are constructed of wood and the fourth side consists of a screen which is pulled down only in rainy weather, perfect ventilation being thus assured. The main feature of the open-air treatment is the sun-bath. On the top of the sanatorium proper, which was once a colonial residence, a large open space has been arranged, fitted with cots and lattice work. Here the patients are compelled to lie naked for a certain length of time every fine day, turning their bodies about so that they may receive on each part the direct rays of the sun. The whole cuticle of each patient is soon as tanned as are the neck and arms of a summer yachtsman. Following the sun-bath the patient is made to undergo a needle-bath, the temperature of which is regulated by the operator, ending with a sluicing down with cold water at a forced high pressure. A rub-down comes next, leaving the whole skin in a glow, and then the patient is dressed and sent outdoors. Very little medicine is given, the bill of fare is liberal and the patients are permitted to eat almost anything they fancy. A large vegetable garden is connected with the sanatorium. Patients are not allowed to visit one another in their rooms, and the rule against expectoration is rigidly enforced. This institution is not intended for advanced cases, but merely for incipient ones, which the managers declare can be treated in such a manner as to put new vigor into the patient and send him home with renewed interest in life.

More Deaths from Lockjaw.—Three more deaths from lockjaw have occurred in Camden, N. J., just when the Board of Health and the local physicians believed all danger was over. All three deaths are of children and cases not before reported. The vaccination in each instance was performed at a different place and no two were treated by the same physician. In all three, tetanus antitoxin was used with apparently good results, the jaws becoming loosened and convulsions suspended, but in each instance there was a recurrence of the spasm and death came suddenly.

The Bubonic Plague.—A telegram from the Governor of the Cape of Good Hope reports that for the week ending November 13th the only cases of plague at the Cape occurred at Port Elizabeth, where there were five cases with three deaths. At Mauritius there were 83 cases and 56 deaths. Liverpool has been declared free from the plague, no fresh cases having been reported during the past ten days. Glasgow is now officially declared free from the plague, no new cases having been reported for three weeks. The Central Station Hotel, where the original patients were employed, has been thoroughly disinfected and is now open for business. The mortality from the plague in India still runs high, being between 8,000 and 9,000 deaths a week. The city of Calcutta has at last awakened to the vile sanitary condition not only of the native quarter, but of the business and residential districts as well. The Health Department has now divided the city into four districts, each under the supervision of an engineer with a corps of sanitary inspectors, who will to a large extent work independently. Model dwellings are being erected for the poor, but it is doubtful whether they will prove successful. The entire drainage system, hitherto remarkably defective for a city of its size, is to be repaired and extended, and the inauguration of a continuous water-supply is contemplated. Fifteen miles of wide new streets are to be carried through the town, replacing the dark and filthy alleys where cholera and smallpox have always been more or less prevalent.

Lunacy in Ireland.—According to the recent report of the Inspectors of Lunatics for Ireland, lunacy is on the increase in that country and at a rapid rate in proportion to the population. The number of cases discharged as recovered during the year represented 8 per cent. of the average number resident, and the deaths amounted to 8 per cent., as calculated on the same basis. A high rate of mortality from phthisis prevails. The extreme liability of the insane to contract tuberculosis is well known, but the question of building isolation hospitals for them presents special difficulties, such as would not arise in ordinary hospitals. The returns show a rapid

increase in the number of cases of general paralysis, a disease which was comparatively unknown in Ireland not many years ago.

Borax as a Food Preservative.—A fish-dealer of Morecambe, England, was recently haled to court for selling shrimps which had been preserved with borax. The expert evidence given in the case stated that the borax kept the shrimps unchanged in appearance for months, and doubtless was in one sense desirable since it prevented the shrimps from becoming poisonous by undergoing putrefactive change. For the defence it was urged that the dealer soaked the shrimps in salt and water for eight hours and then boiled them. The question arose as to how much of the borax would be removed by this treatment, but none of the witnesses could give any definite information on this point. An analytical chemist said that he did not consider the amount of borax, 95 grains to the pound, excessive, and doubted if a less quantity would preserve the shrimps. Mr. A. S. Barling, surgeon to the Royal Lancaster Infirmary, said that he had given boric acid and borax in doses of 60 grains daily to numbers of patients without any ill-effects. It was suggested that the borax might be of advantage in destroying possible sewage organisms which so often infect seafood caught near shore. The defendant, however, was found guilty and fined the maximum penalty of £20.

Royal Tuberculosis Commission.—The Royal Tuberculosis Commission, which is now in session at Westminster, London, England, has arranged to carry out the experimental part of its work at two farms in Essex, which have recently been placed at their disposal. It is not expected that detailed reports will be made for some time.

The Sensations of Electrocution.—M André Broca, Professor of Physics, Paris, while experimenting with a Rhumkorff coil received a shock with a powerful current. Fortunately for the Professor, he held in each hand a very large electrode, to which circumstance he owes his escape from burns. On receiving the shock he was thrown to the ground, felt as though his heart had ceased to beat, tried to call to his assistant, but could not articulate. He had no feeling in arms or legs, and the walls of the room seemed to have turned green and inclined obliquely. When the current was cut off the Professor was assisted to rise and was able to walk slowly, though feeling as if he possessed but a head and two legs; he tried to move his arms, but they were paralyzed. When the arms were sharply pinched he felt nothing; while, on the contrary, his fingers were hyperesthetic. He was able to walk home and go up five flights of stairs without much discomfort, and after two days he felt perfectly well. It is noteworthy that after receiving the shock M. Broca retained perfect consciousness and said to himself that he was dying.

Obituary.—Dr. Henry Clarke Houghton, one of the best known homeopathic physicians in this country, died on Saturday afternoon at his home, 7 West Thirty-ninth Street. He was sixty-four years old, was born in Roxbury, Mass., and after a business education at the Ridgewater Normal School, began his medical studies in the Maine Medical School. Later he went to the Portland School of Medical Education, from which institution he entered the New York University, where he was graduated with the degree of M.D. in 1867. When he died Dr. Houghton was professor of physiology in the New York Homeopathic Medical College and in the New York Medical College and Hospital for Women. He was dean and professor of otology at the New York Ophthalmic Hospital and president of the New York State and New York County Homeopathic Medical Societies.

Dr. Henry Sutherland, for many years lecturer on insanity at Westminster Hospital, London, died November 19th.

Dr. John Connell, of Peebles, Scotland, well-known classicist and scholar, died November 2d.

Dr. Wm. G. N. Manley, Surgeon-General, British Army, Medical Department, died November 16th. For his services in the Franco-German war he received the Iron Cross. He also served in the Afghan, Egyptian and Zulu wars, receiving many honors for meritorious services.

Dr. David McDiel, Surgeon in the United States Penitentiary at Fort Leavenworth, Kan., died last week from the effects of a stroke of apoplexy. He was forty-one years old.

Dr. Isaac Newton Evans of Hatboro, Penn., who was a member of the Forty-fifth, Forty-eighth, and Forty-ninth Congresses, from the Seventh District of Pennsylvania, died suddenly of heart disease at his home Wednesday, aged seventy-four years. He was born in Chester County, Penn., and was graduated in medicine from Bowdoin College, Maine, and Jefferson Medical College, Philadelphia. Besides being a member of the American Medical Association, he was once President of the Doylestown (Penn.) Bank, and later of the Hatboro National Bank.

Sir William MacCormac, Bart., president of the Royal College of Surgeons, died suddenly from heart disease at Bath, England, Dec. 4th. His health had caused anxiety for some time past. Sir William MacCormac was born in Belfast in 1836, being the son of a physician, Dr. Henry MacCormac. He was honored by many societies in his life for his services to science. He received his education in Belfast, Dublin and Paris. After making a reputation as a surgeon in the hospitals of the United Kingdom and winning the gold medal of the Queen's University he saw service at Metz and Sedan in the Franco-German War as surgeon-in-chief of the Anglo-American ambulance, and also during the Turko-Servian War, in 1876. For twenty years he was one of the senior surgeons and lecturer at St. Thomas' Hospital, London, as well as consulting surgeon and examiner in many other institutions. In consideration of his services as secretary general of the International Medical Congress, held in Lon-

don in 1881, the Queen knighted him. In 1897, at the Queen's Jubilee, he was made a baronet and appointed surgeon-in-ordinary to the Prince of Wales, now the King, whom he attended when suffering from the effects of an accident. Many foreign governments honored Sir William. When the Boer War broke out he went with the British Army to Africa, and was present during the early fighting in Natal. He was the author of a great number of treatises on various subjects, most of which were contributed to different medical journals or societies. Among these may be mentioned: Surgical operations, Antiseptic Surgery, Notes and Recollections of an Ambulance Surgeon. In 1899 he delivered the Hunterian oration before the Royal College of Surgeons.

CORRESPONDENCE.

OUR LONDON LETTER.

(From our Special Correspondent.)

LONDON, November 23, 1901.

THE "LACNANTHES" TREATMENT OF CONSUMPTION—VIOLET LEAVES AS A CURE FOR CANCER: AN EXTRAORDINARY CASE.

OWING doubtless to the dearth of more sensational matter, the newspapers, as is their wont, have been edifying their readers with accounts of wonderful new "cures" of one kind or another. For the last three months a controversy about the treatment of tuberculosis has raged in the *Times*, which, if it has not been particularly instructive, has at any rate tended to relieve the habitual solemnity of that austere print. It was started by a man of some position in society who is under the impression that his wife was cured of consumption by the treatment of one Alabone, whose name was struck off the *Medical Register* some years ago for unprofessional conduct. Nevertheless he has continued to practise as before, as indeed any one may do here at his own risk. If he does not give himself out to be a legally qualified practitioner, and if no patient actually dies on his hands, the law will not meddle with him. The remedy to which Alabone attributes the success which he claims is *lacnanthes tinctoria*, or redroot, a plant of which our pharmacologists and therapeutists seem to know little or nothing, but which, I see, is said in Gould's *Dictionary of Medicine* to be "popular in parts of the United States as an expectorant and alterative in pulmonary tuberculosis." It would appear, however, that Alabone himself is by no means so thoroughgoing a believer in the virtues of his supposed panacea as the people who put their trust in him have been led to believe. At any rate I have seen a document written by his son, a qualified member of the profession who wears the mantle of which the paternal prophet has been stripped, in which he protests against their treatment being called the "lacnanthes cure." On this it may be remarked that if it is so known, that is entirely the fault of those who have come forward to vaunt its marvelous effects in the public press. The fact is doubtless that the "lacnanthes cure" has had rather more advertisement than is good for it; the constitution of these nostrums is naturally frail, and they do not bear exposure to the searching wind of criticism. It is not surprising therefore that Alabone should now prefer to rest his claims as a discoverer on something a little more occult. Accordingly one hears of a wonderful atomizer by means of which diseased lungs are supposed to be impregnated with sprays of various kinds. As far as one can gather those sprays contain nothing more than creosote, formaldehyde, menthol, and such like substances which have been used for the same purpose by practitioners in all quarters of the globe. A mystery is, however, made of the excipient; moreover, the apparatus is so complicated that it cannot be intelligibly described, and so difficult to manage that it cannot be used except under the personal direction of its ingenious inventor. The whole thing is so transparent a piece of quackery that it would not be worth mentioning but for the unpleasant commentary on the impenetrable darkness of the public mind in regard to medicine which it supplies. Numbers of otherwise sane and decently educated people have come forward to testify to cures of hopeless cases of consumption wrought under their own eyes by Alabone's treatment. The profession is publicly accused by people who ought to know better of persecuting a scientific discoverer, and striving for selfish reasons to "suppress" an infallible remedy. All this in the face of the fact, "gross as a mountain open, palpable," that the supposed specific has never been brought before the profession, and that Alabone has declined to have his method tested in a hospital for consumptives except under conditions which would make the test utterly worthless.

Quite lately a new "cancer cure" has come to dispute the public interest with the consumption "cure." A "lady of quality" (as our great-grandfathers used to say), Lady Margaret Marsham, sister of the Earl of Romney, had been suffering for several months with disease of the throat which was judged by the doctors who saw her to be cancerous. The disease increased to such an extent that she could only with great difficulty be fed through a small tube. There was a large mass of fungating growth on the outside of the neck. A small piece of the tumor was removed from the inside of the throat, and sent to the Clinical Research Association, a body which makes histological examinations for practitioners. The report was that the growth was an epithelioma. The case seemed to be past all surgery, and the old lady's life was regarded as a matter of days. In these circumstances another lady of quality, Lady Mary Ross, intervened and suggested the application of an infusion of violet leaves which she had heard mentioned in her young days as useful in cancer. As there was no hope from any other quarter, the remedy was

tried. The following is the formula as given in an enterprising newspaper:

"Take a handful of fresh green violet leaves and pour a pint of boiling water upon them, cover them and let them stand twelve hours, until the water is discolored and green. Then strain off the liquid, dip a piece of lint into the infusion, of which a sufficient quantity must be warmed. Put on the wet lint hot wherever the malady is. Cover the lint with oil silk or thin mackintosh and change it whenever dry or cold. The infusion should be fresh about every alternate day."

The effect of this application is described by a sister of the patient as having been "almost like a miracle." The external tumor disappeared in a week, the internal disease vanished in a fortnight, and Lady Margaret Masham is said to be now in good health and able to travel and visit her friends. Well, the skeptic may say, we have heard all this kind of thing before; it is the usual fairy tale of marvelous cures which one reads of in the pamphlets of vendors of quack remedies. But the case of Lady Masham differs from these in the important circumstance that all the particulars are fully certified by the testimony of competent medical witnesses. They naturally do not care to come before the public in connection with such a case, but had there been any room for denial of the facts or even for mitigation of their thaumaturgic character, they would certainly have considered it their duty to attempt to enlighten the public on the subject. Lymphosarcomatous tumors have, I believe, been known to disappear completely without any obvious cause; and cancer in aged persons occasionally contradicts what have somewhat arbitrarily been fixed as the laws of its evolution. But epithelioma of a moist cavity like the mouth is usually, as everyone knows, of intense malignancy. The only loophole of escape from the difficult strategical position in which this case appears to place medical science is the possibility of an error in the microscopical diagnosis. The fallaciousness of histological evidence as to the nature of tumors was conspicuously shown in the case of the late Emperor Frederick, and experienced clinicians refuse to accept the microscope as at all times and in all circumstances a perfectly trustworthy guide. In the case in question there is the further possibility that a mistake may have been made in the specimen. In a laboratory where large numbers of specimens are received every day confusion may easily arise as to the source of a particular one; this is known to have occurred in at least one previous instance.

There the case remains for the present; the profession will look forward to a full report from the physicians in attendance at the proper time. In the meantime the public will doubtless pin its faith on violet leaves, and many a sufferer will let his chance of cure or relief slip away by trusting to a useless remedy. I have already heard of one case in which the last hours of a poor woman dying of cancer of the breast were embittered by the disappointment of false hopes excited by the announcement of the violet cure. The wonderful case of Lady Margaret Masham may indeed have evil effects of a very far-reaching kind, for her relative, Lord Romney, is a personal friend of the King. Now, His Majesty in a public deliverance not long ago spoke strongly of the importance of finding a cure for cancer. If he should allow himself to be misled into making any public recommendation of violet leaves as a remedy, the effect among his loyal subjects—most of whom, as Carlyle said, are fools—would be simply disastrous.

TRANSACTIONS OF FOREIGN SOCIETIES.

German.

SURGICAL TREATMENT OF DISEASES OF THE LUNGS.

QUINCKE (Kiel) at the Seventy-third Congress of the German Naturalists and Physicians, held in Hamburg from September 22d to September 28th, read before the Section on Surgery a paper on the surgical treatment of diseases of the lungs in which he made the following points. He said that surgery of the lungs is only in position and, in fact, has but one task, *i. e.*, to provide exit for pus. He then described the mechanical and bacterial factors in pus formation and the predisposition to it which arises from the disease of the mucous membrane of the small bronchi and especially from the loss of the ciliated epithelium of the mucous membrane. Next come the tuberculous processes. The purpose of operating, the emptying of pus-cavities and their replacement by scar tissue, is in the lung very difficult on account of the peculiarities of position and structure. The difficulties are increased by adhesions to the chest wall and by a thickening of the abscess cavity wall so that it is hard and rigid. It is his opinion that an abscess in the lower lobe is more easily treated surgically than one in the upper lobe. If a large cavity exists in the lower lobe, a mere opening of it usually is sufficient. If, however, it exists in the upper lobe, the removal of several ribs may be necessary. Again, after it has been opened an abscess of the lower lobe is more easily emptied by coughing. The most important point of all is the diagnosis and especially with the microscope. The presence of elastic fibers in the sputum is significant, while their absence does not prove the absence of a cavity. Bacteria must be looked for, especially strepto-, staphylo-, and pneumococci. The pus from cavities usually has a foul odor. When the cavity is in the lower lobe expectoration is usually periodic. The classical symptoms of cavity in the lungs occur more frequently in the upper lobe, perhaps because in this situation they are usually of a tuberculous nature. Those of the lower lobe are not usually so large, are commonly crevices which become more or less filled with secretion. Amphoric breathing is very deceptive. The X-ray is of service only when the abscess is large; it then appears as a bright, illuminated area with a dark circle around it. If one now

wishes to operate an important question is, Are there pleural adhesions? Unfortunately for the physician, signs as to this point are unreliable and the adhesions are apt to be lacking when the pus arises from a chronic bronchitis. It is surprising how often one will be deceived at an operation by finding that all adhesions which were expected are absent. The patient is then likely to die from infection of the healthy pleural cavity with the pus. Gangrene of the lung is always a very bad sign, usually because of the septic intoxication which it causes. After the simple acute and the putrid acute abscesses there are the simple chronic abscesses which are caused, usually, by chronic dilatation of the bronchi (bronchiectasis). The chronic putrid abscesses are very hard to recognize and more hard to reach operatively. He therefore comes to the conclusion that acute processes are comparatively favorable and chronic processes are unfavorable for surgical treatment, and that putrescence, whether acute or chronic, is very unfavorable. Abscesses which are caused by foreign bodies promise good results to the surgeon. Tuberculosis is also rather enticing to the surgeon because the results of operation are really quite good. If one cannot actually attack the abscess cavity itself, it is often of great value to render the affected part of the lung inactive by cutting away the ribs and chest wall over it.

GARRÉ (Königsberg) gave a paper on the same subject beginning with the question of adhesions between the pleural surfaces, which are really a necessary help in all operations on the lungs, the absence of which causes distinct dangers. He says, however, if one were to operate only on adherent lungs, one would be very much limited, indeed. Unfortunately, there is no means of recognizing this condition in advance, consequently every surgeon must be ready to reckon with it. The records show that our fears in this matter have been very much greater than necessary. The great danger in pneumothorax lies in the collapse of the healthy lung on the opposite side and then in the likelihood of an infection. In practice these dangers can be very largely avoided by sewing the two layers of the pleura together or by use of gauze-packing, such as Roux has suggested. Abscesses on the level of the diaphragm are usually easy to reach and treat. A recent acute abscess of the lung may often be cured by simple incision and drainage, exceptionally by simple puncture and drainage. It also may be cured by Nature through a perforation into a bronchus, but the majority of abscesses must be treated on the basis of thick-walled abscesses. The conditions of the lung open to surgical treatment are (1) tuberculosis, (2) actinomycosis, (3) abscesses, (4) gangrene, (5) bronchiectasis, (6) ecchinococcus, (7) neoplasms. As to the method of operation there are also three steps, namely, (*a*) thoracotomy, (*b*) pleurotomy, (*c*) pneumotomy, or sometimes (*d*) partial pneumectomy. For thoracotomy, as a rule, mere division of the soft parts is not sufficient. It is therefore better to cut away several of the ribs and always as much of each rib as overlies the affected part. Cutting through the pleura is safe enough if there are adhesions. If there are not, it is often advisable to do the operation at two sittings, employing the interval for the making of adhesions. A careless opening of the chest is essentially dangerous through collapse. If this occurs the treatment is simple and usually effectual. The lung must be seized with some convenient instrument and drawn vigorously out of the wound. In this way pressure on the sound lung is relieved and that organ begins to act, dyspnea disappears and the pulse becomes strong. Similarly, a rapid sewing of the lung to the wall of the chest, combined with gauze packing, may limit or check the inrush of air into the cavity of the pleura. The site of the abscess of the lung is recognized by discoloration and congestion of the pleura, deposits of fibrin or thickening of the pleura, and by changes in the consistency of the lung tissue, especially if it is circumscribed and if it shows elastic tension or fluctuation. For entrance into such an abscess the Paquelin cautery is the best. It is often difficult to find the abscess, therefore, an aspirating needle is of good service. In acute cases, as a rule, nothing further is necessary than to pack the wound and let the abscess cavity heal from the bottom. In the chronic cases, however, such a procedure is useless, because the pus is under no pressure since the walls of the cavity are rigid. For this reason the outer wall of such a cavity must be removed as far as possible and with it the ribs of the chest wall also, so that the soft parts may sink in and adhere to the deep surface of the abscess cavity. If bleeding occurs from the wounding of a large vessel, packing will usually stop it. Tuberculous cavities are for the most part less promising, probably on account of the nature of the disease. The following operations, however, are at times indicated: (1) A wide opening, free drainage, careful packing in case of retention of secretions and all precautions against a secondary infection with the pyogenic germs; (2) free exposure and removal of the diseased part of the lung combined with a thoracoplasty if the abscess is isolated in the lower lobe; (3) removal of the chest wall and the pleura in addition is indicated when there are single discrete cavities at the apices of the lungs. The methods are as follows: (*a*) Resection of the first three ribs without opening the pleural cavity; (*b*) resection of two ribs with pleurotomy and freeing of the adherent lung; (*c*) the making of an artificial pneumothorax. Actinomycosis of the lung has been operated on but eight times. There are no special indications or technic in gangrene of the lung. The prognosis is very much less favorable, because so many of the cases died as a result of secondary deposits—for example, meningitis, abscess of the brain, embolism. Most of the gangrenous areas occur in the lower lobe and usually with a localized empyema. Bronchiectasis has been op-

erated on fifty-seven times, with twenty-one deaths. The difficulty seems to be to reach the disease without damaging the lung tissue overlying it. There have been eight deaths out of seventy-one operations for echinococcus of the lungs. The use of the needle is unsafe, dangerous and unwise. An open operation is the only safe one. The removal of neoplasms of the lung has up to the present time been very rarely done, for the reason that they are always impossible of early diagnosis and they are inoperable after they have progressed. Helferich attacked a sarcoma near the hilus of the lung. The result in this case was fatal, but it suggests that possibly, with an early diagnosis, tumors of the lung will come within the reach of the surgeon.

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF RUSH COLLEGE (CHICAGO).

Stated Meeting, Held November 4, 1901.

Stricture of Membranous Urethra, Ascending Gangrenous Inflammation of the Entire Urinary Tract.—Dr. L. Hektoen presented the following specimens: The stricture was located a few centimeters from the meatus. Owing to the obstruction great dilatation of the bladder, the ureters, and the renal pelves had resulted, followed by a violent necrosis and gangrene of the entire mucous membrane, which presented a rough, shreddy, and dirty grayish appearance. There was present in characteristic form the necrosis of the apices of the medullary pyramids seen in recent dilatation of the renal pelvis and attributed generally to pressure. At the autopsy (Dr. Wells) the turbid, foul urine in the bladder was covered by a layer of liquid fat, which probably came from the extension of the destruction to the fat at the hilum of the kidneys. No other source for the fat was found. The patient entered the Cook County Hospital in coma and died soon after, so that exact facts as to the previous occurrences were not obtainable.

Healed Ulcerative Endocarditis of the Aortic Valves.—Two specimens were presented of hearts in each of which one aortic valve showed a large rounded perforation, with smooth but thick and sclerotic margins, about 1 c.m. in diameter, situated in the substance of the valve between the line of closure and the base. There was in each case general sclerosis and deformity of the aortic valves, the result of endocarditis, and in one case an acute destructive process was engrafted upon the chronic. The size, the location, the character of the margins of the perforations, as well as the several scleroses of the valves, led to the conclusion that it concerned healed ulcerative processes which probably had caused valvular aneurism with perforation, and that the specimens afforded anatomical evidence of the healing of ulcerative endocarditis, a possibility the occurrence of which is supported by clinical observations.

Ocular Paresis Presenting Unusual Clinical Pictures.—Dr. F. C. Hotz reported two cases of this affection. Paralysis of any ocular muscles causes a deflection of the visual line of the affected eye (strabismus) and diplopia, which is especially noticeable when the eyes are turned in a direction which requires the coöperation of the affected muscle. Under ordinary circumstances these symptoms (strabismus and diplopia) make the correct diagnosis an easy task. But the diagnosis becomes a perplexing problem if the patient prefers using the affected eye, perhaps because it has much better vision than the other eye, or for some other reason; for as soon as the affected eye is made to look straight the other eye will show a marked strabismus. In these cases the diplopia tests are exceedingly valuable for the diagnosis. To illustrate:

Case I.—Salesman, thirty-seven years old, presented himself with a marked convergent squint of the right eye and homonymous diplopia, which had come on about two weeks ago; cause unknown. Apparently paralysis of the externus of the right eye; but the double images came together when the light was moved to the right, and they separated when it was moved to the left. Homonymous lateral diplopia indicates paralysis of the externus and the separation of the images towards the left points to the externus of the left eye as the affected muscle. And the diagnosis was confirmed by the fact that the abduction of the right was normal, while the abduction of the left eye was greatly restricted.

Case II.—A workman, aged thirty-eight years, was struck over the left eye and six weeks later began to see double. The left eye is straight, the right eye is turned down and in. It looks as if the right eye could not be turned up (paralysis of its superior rectus or inferior oblique), but the diplopia test shows the image of the right eye above and to the right of the image of the left eye, the images separating in the upper field and coming together in the lower field. This test plainly shows that the downward movement of one eye is restricted, hence that the affected muscle is one of the depressors (inferior rectus or superior oblique). Homonymous images point to the superior oblique and the image of the left eye being lower points to the left eye. Hence the correct diagnosis is paralysis of the superior oblique of the left eye.

Sarcoma of Iris.—Dr. A. B. Hale presented a case of a young woman of twenty-two years, from whom he had removed a sarcoma of the right iris. The tumor was detected less than three weeks after symptoms of pain had appeared and had been promptly excised—seemingly in a capsule. The microscope confirmed the diagnosis, and the history of the case, together with the subsequent behavior of the eye, which was perfectly normal six months after the operation, indicated a primary sarcoma of the iris without recurrence. (Microscopical specimens exhibited.)

Penetrating Wound of Eyeball.—Dr. Hale also demonstrated an eyeball nucleated sixty hours after a penetrating wound made with a piece of steel from a hammer. The path of the foreign body through the lens to a bed in the choroid anterior to the equator was plainly visible. The eye had shown no inflammatory reaction, but an X-ray photograph was positive. The speaker referred to the progress made during recent years in diagnosis and treatment without the destruction of the eyeball, of such cases, but in view of this patient's age (77) and the unavoidable danger from delay, enucleation had been promptly done with the full consent of the patient.

Epithelioma of Lip and Cornea.—Dr. Wm. H. Wilder showed a man, seventy-one years of age, who seven years before had had an epithelioma removed from the lower lip. A short time ago, epithelioma developed in the upper, inner part of the right orbit, involving the eyeball. The case is under treatment by Dr. Pusey with the X-rays. He also showed a case of a man, fifty-one years of age, from whose right cornea he had removed an epithelioma. Recovery of perfect vision followed the operation. He also showed two specimens of epithelioma of the cornea, one of which was situated on the limbus and the other wholly within the cornea.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, Held November 5, 1901.

The President, Joseph Collins, M.D., in the Chair.

Portrait of Dr. E. C. Seguin.—Dr. J. Arthur Booth presented to the society a portrait of one of its founders, the late Dr. E. C. Seguin. The portrait was donated by Mrs. Seguin.

Case of Disseminated Sclerosis.—Dr. William M. Leszynsky presented a man whom he had first seen about two years ago. At that time he was thirty-two years of age, and stated that he had been well up to eighteen months previously. At that time he had suffered from occasional diplopia, but it had since almost disappeared. He had had occasionally a staggering gait and speech had become slow. There had also been some difficulty in swallowing. There had been no headache, tinnitus or vomiting, and no bladder symptoms. When first seen he had complained of being nervous and emotional. The examination showed him to be healthy in appearance. There was slight hesitancy in speech, and he was disposed to break into tears on slight provocation. There was slight horizontal nystagmus on efforts at fixation. The fundi and the visual fields were normal. His gait was slightly ataxic, and there was slight dragging of the right leg and a tendency to fall to that side. Both knee-jerks and Achilles reflexes were exaggerated. The examination of the urine was negative. On January 23, 1900, there was slight paresis in the left posterior thigh muscles and slight ataxia in the left upper extremity. In May it had been noted that he was not so emotional, but he dragged the left leg in walking, and the scapulæ were prominent. In December it had been noted that the static ataxia was well marked. In March of the present year there was slight rigidity and dragging of the right leg in walking with tendency to fall to the right. At the present time the pupils are normal; there is slight oscillation of the eyeballs; slight ataxia of the right upper extremity; muscular power is perfect; the speech is slow and uncertain; there is a tendency to fall toward the left with a paraplegic gait. He stands with difficulty on either leg alone. Both knee-jerks are equally exaggerated. A specimen of his handwriting was exhibited. During the past year there had been practically only an increase in the cerebellar incoördination and in the defect of speech. The man presented none of the stigmata of hysteria and was in no way neurasthenic. While he did not present all of the characteristics of disseminated sclerosis there were sufficient symptoms present, the speaker thought, to warrant this diagnosis.

Dr. B. Sachs thought there could be no doubt about the correctness of this diagnosis. It seemed to him a good example of the rather rare cerebellar form of multiple sclerosis.

Tumor of the Pons.—Dr. Joseph Collins presented some sections from a tumor of the pons. They had been taken from a woman, about forty years of age, who had gone to a dance on August 24, 1900, feeling quite well. After dancing a short time, the evening being very hot, she fell and remained unconscious for two hours. She said that her head felt heavy and her feet very light. The next morning on attempting to do housework she found that she was very dizzy and that the left side of the body did not seem to be under proper control. During the next three weeks there had been three transitory attacks of unconsciousness. There was in addition pronounced ataxia of the extremities, but no paralysis. There was also constant vertigo with occasional vomiting, and a feeling of great weakness. She also suffered from a distressing diplopia. After an interval of about a week, during which the symptoms had abated, they had again returned. She had then exhibited inebrious speech and had suffered from nausea on the slightest movement. He had seen her about seven weeks after the original attack, and examination had revealed paralysis of the right abducens and of the right facial with no reaction of degeneration; slight anesthesia of the upper two branches of the fifth nerve with no involvement of the lower branch; also hemiataxia and an exaggeration of the tendon jerks all over. There was not much headache at the time, and no optic neuritis. The woman died with symptoms of bulbar involvement. The lesion had been diagnosticated as an acute softening in the left half of the pons. On autopsy a section through the pons revealed a fluid mass,

but no evidence of a tumor or of an increase in the consistency of the pons. It had only been after hardening and cutting the pons that it had been found that there was an enormous angiosarcoma involving the left etage of the pons. It had pushed over the raphe and infiltrated the right half of the pons as well. This explanation of the lack of symptoms that one would expect with such a condition was that the growth had infiltrated between the motor and sensory fibers of the pons, but had failed to destroy them until a short time before the death of the patient. This was entirely at variance with what was usually observed in a growth of this character. Both acoustic nerves had escaped. At no time had there been any loss of vision, though careful tests had been made to determine this point.

Dr. M. Allen Starr said that last March he had seen in consultation with Dr. Biggs a patient who had presented rather a similar set of symptoms, namely, diplopia and paresis of several of the ocular muscles on both sides without a typical ophthalmoplegia externa. The patient also had anesthesia of one side of the face, and had the kind of speech often observed in bulbar palsy, together with a marked ataxia. There was no choked disk, so that the question had arisen as to whether the condition was one of softening of the tumor. In the absence of headache and choked disk he had inclined to the diagnosis of softening, but the autopsy had shown an infiltrating glioma.

Clinical and Anatomical Report of a Case of Multiple Congenital Deformities.—Drs. B. Onuf and J. Fraenkel presented a joint paper, which was read by Dr. Fraenkel. The subject of the report was a girl who at the age of four years had been admitted to the Montefiore Home on September 22, 1895. The condition of the extremities had been noticed immediately after birth, and it was said that convulsions had occurred frequently during the first year. One year and a half before admission an osteotomy had been done at the hospital for clubfoot. During her stay in the Montefiore Home the girl had been frequently examined by various specialists. The child showed normal cerebration, but the emotions were displayed in an explosive manner. The chief features were: Motor disturbance of all four extremities; asymmetry of facial innervation, the face being drawn to the left; atrophy of the muscles of the forearm and fingers; drop-wrist on both sides; decided diminution in the motor power of forearms and hands; absence of the reflexes of the upper extremities; lower extremities decidedly tapering, and the right one the longer; decided diminution of the motor power of the flexors of the leg and extensors of the foot. On attempting to walk, standing erect, an intense lordosis developed, and there was a cock-step gait. The clinical picture had remained practically unaltered up to the time of her death from diphtheria in June, 1897. The autopsy had been made by Dr. George R. Elliott. There was a subluxation of the hand and forearm forward. The palmaris longus muscle was absent. The ulnar half of the flexor sublimis digitorum was much reduced in volume, while the radial half was composed of fat only. The flexor profundus digitorum was also quite fatty. The flexor longus pollicis was converted into fat and the supinator longus into a band. The muscles of the extensor side of the forearm were all small but were not fatty. The thenar muscles were absent with the exception of the flexor brevis pollicis. There was a dislocation of the left hip upward and forward without any break in the capsule, and the head of the bone was situated forward of the natural acetabulum. The new acetabulum was made up of the thickened capsular ligament, but was otherwise apparently normal in shape. The pelvic and thigh muscles on the side of the dislocation were either fatty or atrophic. Microscopical examination of the psoas and entire muscle mass of the three adductors demonstrated: (1) A reduction in the volume; (2) an increase in the perimuscular fat tissue in some, and interfascicular fatty tissue in others at the expense of the muscular tissue proper; (3) increase of the perimuscular fat, chiefly in the adductor group of the left thigh; (4) increase of the fibrous connective interstitial tissue; (5) a vascular change, chiefly a thickening of the vessel walls; (6) disintegration of muscle fibers in some muscles; (7) preservation of a relatively large number of muscle spindle-cells in the affected muscles; (8) changes in the intermuscular nerve bundles, chiefly a scarcity of the nerve fibers and thickening of the perineurium. No less than 44 spinal nerve roots were examined microscopically and changes were found not only in many anterior, but also in many posterior roots. The spinal cord on gross examination showed an unusually meager development of the cervical and lumbar enlargements. Microscopically there were noted: (1) A shrinkage of the nerve cells of the anterior horns in most levels of the spinal cord; (2) a shrinkage of the cells of Clarke's columns in certain levels; (3) vascular changes and cavities in the gray matter, chiefly in the cervical and dorsal regions; (4) the presence of apparently undeveloped cells at certain levels; (5) proliferation of the ependyma of the central canal in certain regions; (6) changes in the white matter, probably by artefacts. On gross examination the brain exhibited nothing peculiar. Changes of an atrophic order and apparently the presence of certain cells in an embryonic state were noted on microscopic examination. The cells most frequently affected were the larger pyramidal cells. No vascular changes were noted. The authors concluded that in this case the primary cause of the muscular changes were thought to be secondary to the spinal changes. To give some idea of the minuteness and exhaustiveness of the examination made of this case it should be noted that 5,500 sections were made and prepared for examination.

Dr. George R. Elliott presented the right forearm and the pelvis of this child, and demonstrated some of the muscular peculiarities noted in the

report. The head and shaft of the dislocated bone, he said, were normal except that they were small from disuse. The dislocation was upward. The speaker emphasized the fact that this was not the form of dislocation known as a cengenital dislocation of the hip; true congenital dislocation of the hip was almost invariably backward on the dorsum of the ilium. The large ligamentum teres seemed to be only a physiological hypertrophy. There was nothing in the drop-wrists to warrant them being called congenital dislocations; they were rather the result of the pareses. With reference to the peripheral theory, Dr. Elliott said he could not quite understand how this would explain the picking out of portions of muscles and having them replaced by fat while others remained absolutely normal.

Dr. B. Sachs said that having seen the child during life he had never doubted that the diagnosis lay between an intra-uterine poliomyelitis and a developmental defect. The paralytic conditions were secondary to the central change. In spite of the elaborate investigation that had been made the report was not wholly satisfying as to the character of the process. It did not seem to him that developmental defect of the gray matter of the cord could not be excluded by the findings reported. It would have been interesting to follow up the anterior spinal artery and determine if this vessel were properly developed and had functionated properly. If it had not been normal, almost all of the changes in the gray matter described in the report could have been easily explained in that way. The case seemed to him to offer an example of a possible arrest of the development of the gray matter of the cord. He would like to know whether any unquestionable case of intra-uterine poliomyelitis had been reported.

Dr. V. P. Gibney said that, so far as he knew, this was the first case of intra-uterine poliomyelitis that had been reported. In various discussions on clubfoot the subject of intra-uterine poliomyelitis had been pretty effectually disposed of. He agreed with Dr. Elliott that the dislocation in this case was not a true congenital dislocation of the hip.

Dr. Joseph Collins said that, judging from the report, he would not be satisfied to admit that the case was one of infantile poliomyelitis, because nothing had been said regarding the changes in the substance of the cell as evidence that these cells had undergone the parenchymatous changes which cells do suffer in poliomyelitis of every kind. He understood that the reason these changes had not been described was because the specimens had not been properly hardened for the Nissl stain. This was a great obstacle to the acceptance of the statement that the lesions were dependent upon a poliomyelitis. In poliomyelitis of every kind the external contour of the cord does not change, yet in the case reported shrinkage of the cord was prominent. Again, the cells were reported to be quite scarce, but the cells themselves were not materially disintegrated as should have been demonstrable in specimens so prepared. He found it impossible to imagine that this perceptible decrease of cells in size and shape in the motor region was purely secondary to the smallness of the cells in the cervical and lumbar regions. The changes in the muscles seemed to indicate very distinctly that they were secondary to central changes.

Dr. B. Onuf closed the discussion. He said that he thought that even if the anterior spinal artery had been badly developed it would not explain why the changes observed were so much more marked in some regions than in others. The intramuscular nerve bundles appeared degenerated. If there had been a developmental defect in the spinal cord one would look for absence of certain nerves and expect the rest to appear normal. In his opinion, the changes found in this case were fairly typical of poliomyelitis. The number of the cells appeared, on the whole, to be diminished. If this were a case of intra-uterine poliomyelitis it was probable that comparatively few lesions would be found so long afterward as evidence of the process that had taken place. The changes of contour were probably explicable also on the ground that the process had lasted long. The distribution of the cell changes was far from being uniform. He saw no reason why the cortical changes should not be looked upon as secondary in view of the fact that the process must have occurred very early in life. In cases of congenital porencephalus of the right occipital lobe marked atrophy of the optic nerve had been observed and reported. In a case of this kind it was not right to draw conclusions from one or two points, but only after a careful study of the whole picture.

The Finer Microscopical Structure of the Cortical Areas in Man and Some Animals.—Dr. M. G. Schlapp made some remarks on this subject. He said that he had been struck with the great differences in the descriptions of the cortex as given by different writers. The earlier authors described five or six layers in the occipital lobe, whereas more modern writers described eight or even nine layers. These discrepancies he would explain by the fact that different animals had been used for their observations. The higher one goes in the animal kingdom the more the philogenetic secondary center tends to replace the philogenetic primary center. The secondary center does not control all movement, however. Plates were exhibited to show the differences in different animals. The motor area is not developed in the lower animals, so that it can not be distinguished from the rest of the cerebrum, but such an area can be observed in the dog and monkey. In the dog it is very near the frontal pole, whereas in the monkey it is much further back. In the monkey is found an eight-layer structure. The cortical sight center is very much developed in the monkey and in man. These differences in structure were demonstrated under the microscope. The granule cells are

characteristic of a highly-developed cortex. Most of these cells have ascending axons or very short axons. They are the cells which receive the impulses. These cells are very much more developed in the sensory than in the motor areas. In the sight center is found the eight-layer type. The auditory center can be recognized, but is not so sharply distinguished as is the sight center.

BOOK REVIEWS.

A TEXT-BOOK OF BACTERIOLOGY. By GEORGE M. STERNBERG, M.D., LL.D., Surgeon-General of the United States Army. Second Revised Edition. William Wood & Company, New York.

THE preface of the book explains its present status. At the request of the publishers the author has again undertaken a revision of his Manual of Bacteriology published in 1892. This is practically a third edition of that work, although the title was changed in 1896 and it now appears as a second edition of the Text-book of Bacteriology. A number of additions have been made to the present edition, including a section on Protective Inoculation in Infectious Diseases and one on the Bacteria of Plant Diseases. In order that the size of the work might not be materially increased, descriptions of species imperfectly described or of minor importance have been omitted.

General Sternberg's well-known volume on Bacteriology needs no introduction to medical readers. The book has been for nearly ten years one of the standard works in American medical literature and an acknowledged authority on its subject all over the world. The present edition, with its magnificent colored plates and handsome illustrations, and the thoroughly up-to-date revision of the text, worthily maintains the reputation of the book and of its author. The new chapters in the book are especially complete and satisfactory. Dr. Sternberg's admirable chapter on Susceptibility and Immunity is now fully supplemented by the article on protective inoculation. The treatment of this subject from the historical, scientific, experimental and the practical sides leaves nothing to be desired. The very full treatment accorded recent work in protective inoculations for cholera and plague as well as many of the infectious diseases in animals gives an excellent idea of this very important and very promising field of bacteriological work.

The section on the Saprophytes with its articles on bacteria in the air, in water, in the soil, on the surface of the body and the exposed mucous membranes, of the stomach and the intestines, of cadavers and putrefying material from various sources, and in articles of food are of special interest because of their significance for sanitation. This part of the book is worthy of careful reading by every general practitioner because it gives the latest ideas on these all-important every-day features of life in health and disease.

The chapter on the Bacteria of Plant Diseases introduced into the present volume is of interest mainly from a purely bacteriological or scientific standpoint, but it indicates the significance that comparative pathology has for medical men even when the subjects of disease are of the lowest order of living things.

A MANUAL OF MEDICINE. Edited by W. H. ALLCHIN, M.D., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital, London. Vol. III. Diseases of the Nervous System. The MacMillan Company, New York.

THIS third volume of Dr. Allchin's Manual of Medicine not only maintains the high reputation of the series of manuals, but enhances it to a notable degree. Than nervous diseases there is perhaps no subject in which it is more difficult to do the compression necessary for a brief text-book and yet uphold the interest of the subject and keep the treatment of it from being too technical. In the present work the ideal has been kept well in view and approached, it would seem, almost as nearly as is possible.

The chapter on The Neuron in Its Relation to Diseases of the Nervous System, with its thorough discussion of the application of recent discoveries in minute nervous anatomy to cerebral and spinal-cord affections, is especially interesting and commendable.

The chapters on Diseases of the Spinal Cord are followed by an excellent table for the localization of lesions of the cord and its afferent and efferent nerves.

The chapters on Functional Diseases of the Nervous System, with their wealth of suggestion for the general practitioner, are very complete yet very concise and direct. Cortical fits and infantile convulsions are given consideration here, though it is usual to think of at least the first of these spasmodic affections as having some organic basis.

Considering its importance as compared to other occupation neuroses, it would seem that too much attention is given to writer's cramp and too little to the many affections that follow any habitual motion in an occupation if done to excess or under unfavorable mechanical conditions. The other occupation neuroses do not so often prove disabling, but they are a source of much pain and discomfort whose real cause is often ignored while treatment is falsely directed to the relief of the symptomatic discomfort.

The book is very takingly gotten up and is of a size and weight calculated not to discourage frequent and prolonged consultation. It is to be hoped that this series will inaugurate a movement that will provide lighter and more convenient text-books than the cumbrous tomes now all too common.

THE READY REFERENCE HAND-BOOK OF DISEASES OF THE SKIN. By GEORGE THOMAS JACKSON, M.D. (Col.), Chief of Clinic and Instructor in Dermatology, College of Physi-

cians and Surgeons, New York; Consulting Dermatologist to the Presbyterian Hospital, New York, etc. Fourth Edition. Lea Brothers & Co., New York and Philadelphia.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN. By JOHN V. SHOEMAKER, M.D., LL.D., Professor of Skin and Venereal Diseases in the Medico-Chirurgical Hospital and College of Philadelphia; Physician to the Philadelphia Hospital for Diseases of the Skin, etc. Fourth Edition. D. Appleton and Company, New York.

THESE two books have each passed through four editions and are also alike in having attained to more than a passing popularity. The specialty they treat of is one of such importance to the general practitioner that the demand for reliable hand-books on dermatology is great, and either one of the volumes under consideration has well deserved its success and is adapted for practical every-day use.

Dr. Jackson arranges his diseases alphabetically, a plan that greatly facilitates reference and in the present state of knowledge is as satisfactory as attempts at pathological classification. Conciseness and system are the most prominent features of the book, which is most commendably free from unnecessary matter, while the important subjects of diagnosis and treatment always receive adequate consideration. The volume is truly a *multum in parvo* and gives an encyclopedic amount of information in compact and practical form. A useful feature is the incorporation of a large number of foreign titles, and the illustrations are abundant and satisfactory. This edition differs from its predecessor mainly in the addition of sections on some unusual lesions and the omission of pronunciations, both changes that are to be commended and increase its value.

The second volume is a much larger and more detailed work, while Dr. Shoemaker's eminence as a teacher of materia medica and therapeutics gives more than usual interest to the sections on treatment. These are never disappointing and evidently represent the fruit of wide clinical observation aided by an intimate knowledge of the remedial resources at our command. As in his other works, the author's personality stands out strongly from his pages and lends a tone and color that makes their perusal pleasant as well as instructive. A particularly interesting chapter is the one on the general considerations of dermal anatomy and physiology, with the principles of diagnosis and treatment, which admirably prefaces the study of the separate lesions in detail.

TRANSACTIONS OF THE TWENTY-SECOND ANNUAL MEETING OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION, held in Washington, D. C., May 1, 2 and 3, 1900. New York, Carey Printing Co., 1901.

THIS is a cloth-bound volume of 235 pages, of good "make up," being uniform with its predecessors. Twenty-five papers are discussed. Those of greatest interest relate to methods of dealing with deflected septum and diseased middle turbinates. Atrophic rhinitis comes up again for consideration, as it ever will—like consumption—until a cause and a cure are found. The papers are of more than average merit; but the value of the book lies in what it is—the transactions of the Association.

SAUNDERS' QUESTION-COMPENDS. ESSENTIALS OF REFRACTION AND OF DISEASES OF THE EYES. By EDWARD JACKSON, A.M., M.D. Third Edition. W. B. Saunders & Co., Philadelphia and London.

THIS third edition of the author's "Question-Compend" is improved in the closing chapters by the addition of new matter on "Injuries of the Eye by Traumatism," "The Ocular Symptoms and Lesions of General Diseases" and "Tests and Requirements of Vision for Schools, Railroads and Public Services." The question-and-answer form of the teaching has its merits and demerits. When due allowance is made for the latter, there is no doubt of the great gain in vividness and directness of information conveyed in this manner and the ease of acquiring it. The more concise, the more difficult. Hence the greater care and skill required to state well both question and answer. The author succeeds in the main, seldom falling into irrelevancy, and then only in a minor degree, as in the answer to "What is Rupture of the Sclera?" Criticism is gratuitous of work so well done as that which this book presents. It well fills the place for which it is designed.

THE PRINCIPLES OF HYGIENE: A Practical Manual for Students, Physicians, and Health Officers. By D. H. BERGEY, A.M., M.D., First Assistant, Laboratory of Hygiene, University of Pennsylvania. W. B. Saunders & Company, Philadelphia and London.

ONE of the best indications of the trend of modern medicine towards hygiene and the prophylaxis of disease is the number of text-books on the subject of hygiene that are finding publishers. Dr. Bergey's volume of about 500 pages is not meant to take the place of the longer and more ambitious text-books on this subject, but, as stated in the preface, is meant as a manual for students of medicine, for students of architecture, and for physicians and health officers who require a compact statement of the practical principles of hygiene as they have come to be recognized in recent years.

The chapters on Ventilation and Heating are especially practical and are very suggestive for persons who do not wish to enter too deeply into these subjects. The chapters on Water and Sewage Analysis are very succinct, yet reasonably complete presentations of a difficult and complex subject. About 70 pages are taken up with the quarantine laws of the United States, inter-state quarantine regulations and Pennsylvania quarantine regulations. The necessity for

printing these regulations *in extenso* is not quite manifest. A digest of the laws and regulations would have served the purpose of the manual very well and would have made the book more practically valuable by allowing the author to devote more space to certain portions that are of special importance. Apart from this the book is an excellent compendium. Its quality as a manual of hygiene rather than a text-book should perhaps have been hinted in the title. For the limited use for which it was intended the volume will doubtless prove popular, for it bears marks of having been written by one who knows from years of teaching the practical difficulties of his subject.

SIXTH INTERNATIONAL OTOLOGICAL CONGRESS. Transactions. Edited by E. CRESWELL BABER. The Southern Publishing Co., Limited, London.

THIS volume of transactions, consisting of 477 pages, may be said to represent the latest views up to the date of the Congress held by the world's representative otologists on the important subjects considered. Unquestionably the greatest interest of the Congress centred around the subject of the mastoid operation in chronic middle-ear suppuration. Views most widely differing are presented; but the current of opinion sets steadily in the direction of the leadership of Prof. MacEwen in his advocacy of operative interference. As was to be expected, a conservative force of great strength and good judgment, occupied an intermediate position between the extremes of operative and *laissez faire* treatment. Thirteen nationalities are represented in the contributions. These transactions are so valuable that we should judge them worthy of something better than their present paper binding.

NERVOUS AND MENTAL DISEASES. By ARCHIBALD CHURCH, M.D., Professor of Nervous and Mental Diseases and Head of Neurological Department, Northwestern University Medical School; and FREDERICK PETERSON, M.D., Chief of Clinic, Department of Nervous and Mental Diseases, and Clinical Lecturer on Psychiatry, College of Physicians and Surgeons, New York. Third Edition. W. B. Saunders & Co.: Philadelphia and London.

Two editions of this work have been exhausted in as many years. This is perhaps the best possible sign that the work, though bearing signs of compression, is written in a manner that makes it especially useful to the general practitioner. There is no doubt that considerable of its popularity is due to the fact that it furnishes in a single volume thoroughly practical treatises on the two important subjects that are at the present moment attracting ever more and more attention—neurology and psychiatry.

In the preface to the third edition the authors state that a conscientious attempt has been made to thoroughly revise every portion of the work, both by additions to its subject matter and by rearrangement, wherever necessary to make it more acceptable to the student and practitioner. Such changes especially have been made as actual use of the book in class work has suggested. A number of new illustrations have been added and a number of sections entirely rewritten. There is about the book a very commendable air of easy simplicity that invites attention to subjects often made forbidding. The work is written so entirely from a clinical rather than a theoretical standpoint that its popularity is not difficult to understand. The illustrations are well chosen and add greatly to the value of the text. The therapeutic hints are always as full as is possible in the rather unsatisfactory treatment of nervous and mental diseases and on the whole the book is a thoroughly practical presentation in simple form of difficult subjects.

A TREATISE ON MEDICAL JURISPRUDENCE. Based on Lectures delivered at University College, London. By GEORGE VIVIAN POORE, M.D. (Lond.), F.R.C.P., Professor of the Principles and Practice of Medicine, University College, London. Longmans, Green & Co.: New York.

THIS book is intended to place the ordinary practitioner of medicine and of law in possession of the facts which occupy the middle ground between these two professions, a knowledge of which is essential. They were taken as a series of lectures delivered at the University College, London, and preserve the easy colloquial style of such discourses.

After a brief and interesting historical introduction, the author takes up in a very fascinating chapter, The Legal Relations of the Medical Profession. This chapter can be read to advantage by every practitioner. Following are chapters on Death, Putrefaction, Persons Found Dead, Poisoning, Symptoms of Poisoning, corrosive acids, caustic alkalies, phosphorus, arsenic, antimony, mercury, zinc, copper and lead, Vegetable and Animal Irritants, Food Poisoning, Narcotic Poisons including most of the poisonous alkaloids, Identity, Sex-Sterility, Rape, Sexual Crimes, Seminal and Blood Stains, Pregnancy and Abortion, Wounds, Drowning, Hanging, Fire, Starvation, Life Assurance and Insanity.

Thus the material covered is that usually found in similar manuals. Although the form is not as attractive as many, yet the work is well worth having.

BOOKS RECEIVED.

ORIGINAL ARTICLES.

THE MODERN URETHROSCOPE.

BY WILLIAM K. OTIS, M.D.,

OF NEW YORK;

CONSULTING SURGEON, CITY HOSPITAL; ATTENDING SURGEON, ST. MARK'S HOSPITAL; FELLOW OF THE NEW YORK ACADEMY OF MEDICINE; AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS, ETC.

THE introduction of electric illumination and the more recent improvements in the construction of suitable incandescent lamps have rendered the modern urethroscope so simple and efficient that, from an instrument having a comparatively limited value among a few specialists, it has attained a prominent position in the armamentarium of genito-urinary surgery.

The difficulty of obtaining a suitable illumination of the urethroscopic field, which so hampered practical examinations with the older instruments, has been overcome by two separate and distinct methods, one or the other of which is now used in all forms of the modern urethroscope.

In one of these the source of illumination (the electric lamp) is introduced into the urethroscopic tube close to the mucous membrane, which it directly illuminates, while in the other the source of light is altogether outside the tube, the field being illuminated by rays of light thrown down the tube, either by a reflecting mirror, prism, or lens, as the case may be.

As early as 1867, Bruck of Breslau constructed an instrument, which was the prototype of the first of these methods, in which the light obtained from a platinum wire heated to a whiteness by a curent of electricity was employed, and this idea has been utilized by Nitze, Oberländer and Wossidlo in instruments which still have their advocates. It certainly is a tribute to the energy, perseverance, and infinite patience of these gentlemen, and their adherents, that they have clung so tenaciously to this expensive and complicated instrument, with its cumbersome battery, annoying water-cooling apparatus, rheostat, and the constant liability of burning the urethra, or of burning out the platinum wire (which was exposed to the air and had to be kept continually at a heat just short of destruction). The time wasted in its use, together with the difficulty of making urethral applications, all greatly offset the advantages derived from improved illumination.

About 1890 a New York electrician (Stammers) constructed a urethroscope at the instance of Dr. Henry G. Piffard, consisting of a minute incandescent electric lamp introduced by a holder into the urethroscopic tube which, while efficient as far as illumination was concerned, failed to prove very successful on account of the amount of heat produced by the lamp. In fact, this urethroscope was identical with some of those of the present time except that it did not have the low-tension electric lamp, which at that time had not been invented.

More recently a firm of electricians of Rochester, N. Y., developed a most ingeniously constructed and exceedingly minute incandescent lamp, of low tension, giving out almost no heat, but with good illuminating power. This permitted the production of an instrument which obviated many of the objections pertaining to the older forms of internal illumination. It was presented to the profession under the auspices of Dr. Henry Koch of Rochester. There are also two similar instruments bearing the names of Drs. Valentine and Chetwood, which, however, do not differ in principle.

The difficulty with all instruments having an internal source of illumination is that a portion of the field is obstructed by the lamp and its carrier, which, small as it is, is capable of interfering to a considerable extent when the smaller tubes are used. The light is adapted to one length of tube only and although all portions of the urethra may be observed with the long tubes, it is frequently of advantage, when working in the anterior urethra, to use shorter ones. With these instruments it becomes necessary to use a separate light-carrier for each length of tube used. The tiny lamp is tender, easily burned out and apt to be short lived.

All these objections are trivial, however, in comparison with the fact that the urethroscope with internal illumination *is not a good working instrument.*

The presence of the lamp hinders the use of applicators in conveying medicated solutions directly to the mucous membrane and of swabs when bleeding and discharge are present. If this is attempted, the lamp frequently becomes entangled in the cotton swabs, or becomes covered with blood or pus, rendering it, for the time being, useless and a very possible source of infection in subsequent examinations. Attempts which have been made to avoid this well-recognized difficulty by placing a small secondary tube alongside the urethroscopic tube to convey the lamp, with an opening between the small tube and the large one at the distal end through which the rays of light can pass, have resulted in very materially reducing the size of the field and in its unequal illumination.

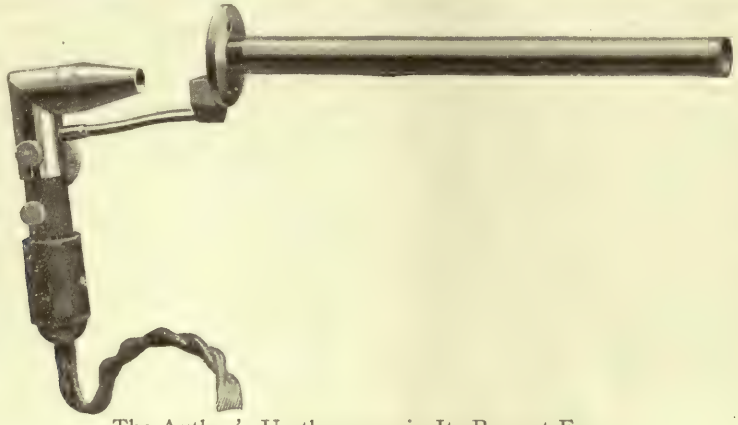
The illumination of the urethroscopic field by a source of light from the outside, reflected into the tube, is as old as urethroscopy itself and far antedates the experiments of Desormeaux, the first to make any serious use of this method of urethral investigation.

Previous to the year 1892, in all forms of the

urethroscope with external illumination, the mirror in some form was used to direct the rays of light and while in many of these instruments this method was fairly satisfactory it was of necessity accompanied by many drawbacks. The dazzling effect of extraneous rays of light on the eye of the operator became exceedingly unpleasant in prolonged examinations, the apparatus was usually cumbersome, even the best of these instruments lacked necessary power and they have been superseded by more modern methods of lighting.

In 1892 I devised an instrument on an entirely different principle from that of former urethroscopes, the rays of light from a small electric lamp being directed through a plano-convex lens to the bottom of the urethroscopic tube, thus attaining a better illumination and obviating most of the objections pertaining to the reflecting instruments.

The instrument in its present form possesses many improvements over the original device, due to alterations which have suggested themselves from time to time and to advances made in electric illumination. I have also to thank Messrs. Wappler & Co. for the excellent manner in which they have put these suggestions into practical form and for the success attained by them in its construction.



The Author's Urethroscope in Its Present Form.

It consists of a metal tube or cylinder, an inch and a quarter in length by somewhat less than half-an-inch in diameter, the first half-inch of which is narrowed down conically to form a funnel-shaped diaphragm, leaving an opening of a quarter of an inch in diameter through which the rays of light emerge. At the other end of this tube is a second tube of the same diameter forming an elbow at right angles to the first tube, three-quarters of an inch in length, into which the handle of the instrument fits. The funnel portion unscrews from the upper tube and a plano-convex lens is placed at this point to concentrate and direct the rays of a small electric lamp placed immediately behind it. This lens can be readily removed for cleaning

The handle consists of a cylindrical piece of hard rubber, about one half inch in diameter and one and a half inches long, to the upper end of which is fixed the electric lamp, while the lower end is arranged to receive the cords leading the current from the battery. A small electric switch in the form of a milled wheel is placed on one side of this handle, a half-turn of which makes or breaks the current. The two small screw-heads are seen on the other side of this handle; the upper serves to clamp fast the hood, the lower to fasten the lamp in position. The lamp is of a variety known as "high efficiency," differing from the others in a special preparation of the filament which enables it to give out a very intense light without a corresponding increase in heat; it is unusually strong and capable of withstanding a current of from sixteen to twenty volts. It is attached to a wire running through the center of the handle, so that it may be raised or lowered and clamped in position by the lower screw.

The only adjustment which may be necessary is, when changing the lamp, to see that the filament of the new lamp comes exactly opposite the center of the lens; a small piece of brass with a pin-hole in it has been placed on the handle behind the lamp socket, so that, by holding this to the light and moving the lamp up or down until the filament is exactly across the center of the hole, the lamp may be clamped in the correct position.

A strong wire connects the instrument to the urethroscopic tube by means of simple joint.

With reference to the length of the handle and the weight of the instrument, both of which have been criticized favorably and adversely, I would say that these depend entirely on the whim of the operator, as the handle may be lengthened to any extent or entirely done away with, while by a slight alteration in material and construction the weight (less than one ounce) may be reduced to a few grains.

The accompanying illustration is from a photographic reproduction exactly half the size of the original. A straight line drawn along the lower edge of the urethroscopic tube through the illuminating apparatus will give a very practical illustration of how little is the interference with

a direct view of the field or the introduction of instruments.

Great pains have been taken and many experiments made to perfect this instrument, with the result that *an illumination of field such as is not found in any other of any type is obtained. It gives the entire field of the tube used, offers no obstruction to the use of applicators, and at the same time nothing is inserted into the urethra which cannot be rendered thoroughly aseptic by boiling. It is simple in construction, strong, inexpensive, and fulfils all the indications of a good, practical, working instrument.*

ADHERENT PERICARDIUM.[1]

BY ROBERT H. BABCOCK, M.D.,
OF CHICAGO.

IT IS so manifestly impossible in the few minutes allotted to me to consider this subject in its entirety and so many of the points bearing on this subject have already been considered by preceding speakers, that it seems best to restrict my remarks to the clinical aspects of this disease.

We meet with adherent pericardium in two forms, (1) as a result of pericarditis interna, which has led to a more or less complete and firm union of the two layers of the sac without adhesion to the surrounding structures; (2) as a result of pericarditis interna et externa, which has caused adhesions not only between the peri- and epicardium, but also between the sac and the contiguous structures, as the chest-wall, diaphragm and lungs. In this second form there is often such an extensive development of fibrous tissue within the mediastinum, with consequent union of all the structures therein contained, that the condition has been termed chronic adhesive or fibrous mediastino-pericarditis. In some cases this proliferation of fibrous tissue is not limited to the mediastinum, but invades the pleural and peritoneal cavities in the form of a general serositis. Not only is the capsule of the liver thickened, but the connective tissue hyperplasia invades the organ, becoming especially marked in the interior of the lobules and in the fissure. In time this fibrous tissue undergoes contraction and the liver becomes reduced in size and hard, very much as it does in hepatic cirrhosis. The once enlarged and chronicly congested organ shrinks, becoming dense and thin bordered, more or less granular, but still fairly regular in outline, excepting that its notch is greatly exaggerated. According to Eisenmenger, it is by the contraction of the connective tissue within the fissure of the liver and consequent compression of the portal vessels that the shrinkage in the size of the organ leads to ascites, as does the atrophy in Laennec's hepatic cirrhosis. (3) Adherent pericardium may exist without chronic inflammatory changes in the endo- or myocardium, but in most instances it is associated with valvular disease or with chronic myocarditis.

Symptoms.—These depend not only on the extent and situation of the pericardial adhesions, but also upon the coexistence or not of other lesions as valvular defects. If the two layers of the sac alone are adherent and particularly if the adhesions are limited in extent, cardiac hypertrophy may be the only effect, and the circulation is carried on so adequately that no symptoms are produced. If, on the contrary, the two surfaces of the pericardium become adherent while the heart is in a state of dilatation from acute myocarditis or in consequence of valvular disease, and if the organ is therefore not able to return to its previously smaller size, the effect upon the circulation is eventually disastrous and symptoms due to stasis declare themselves. If the pericarditis was external as well as internal and led to fixation of the sac to some of the surrounding parts, the heart is held more or less firmly, as if in a vise, and is hampered in its work. Its systoles are less effectual than normal, since the fixation of its walls serves to hold the cavities in a state of distention and its contents are imperfectly discharged. Stasis inevitably results. If to this condition is united a valve lesion, such as mitral regurgitation, the effect is particularly bad and symptoms are not long deferred. It is for this reason that chronic, adhesive mediastino-pericarditis is so likely to prove a serious affection. In all cases there is much difference in the severity and manifestation of symptoms. In one individual these are referable chiefly to stasis within the pulmonary vessels, shortness of breath on exertion, cough due to bronchial congestion, and a marked disposition to attacks of bronchitis. In another case palpitations, either with or without dyspnea, are called forth by effort and excitement, occasioning much discomfort and at times alarm. In these cases the pulse is apt to be persistently rapid, it may be irregular, and the cardiac impulse is exaggerated in force and extent. In a few cases without coexisting valvular defect the disturbance of circulation is not pronounced, being shown only by digestive disorders lasting for years and attributed to simple dyspepsia or to chronic gastritis, but rarely to their proper cause on account of the obscurity of the pericardial lesion and the difficulty or impossibility of its diagnosis.

In most cases there is nothing to distinguish them from ordinary instances of mitral disease or from cardiac dilatation. Physical examination usually discloses enlargement of the liver from passive congestion, and this enlargement is generally greater than one would expect from the cardiac findings, and I have been impressed by the obstinacy of this hepatic engorgement under treatment. It is not only difficult to reduce its size by ordinary means of treatment, but the congestion of the organ displays a striking tendency to recur as soon as treatment is abandoned. I have had under observation for several years

[1] Read before the Section on Medicine at the meeting of the American Medical Association, St. Paul, June 4-7, 1901.

a female patient whose mitral valve leaks and whose enormously enlarged heart is apparently completely encased in fibrous tissue that binds down the organ on all sides, so that neither rest in bed nor digitalis seems to reduce its size in the least. The liver has always been greatly engorged, extending for a long time nearly to the crest of the ileum and requiring the daily use of saline laxatives to relieve the patient of pain and discomfort. For the past year the organ has been gradually diminishing in size and becoming thinner and harder. This patient has displayed remarkably little dyspnea of effort, but is greatly annoyed by the pounding and tumultuous action of the heart, this sensation being specially noticeable in the epigastrium. Of late she has had a great deal of cough, difficult mucous sputum, and upon several occasions slight hemoptysis. She has to be extremely careful in her diet. Her urine and menses have become scanty.

Another female patient, with pronounced mitral insufficiency, has pericardial adhesions that bind down the left side and base of the heart, fixing the apex beat immovably in place, far to the left and downward, but the border of the right heart is apparently free from adhesions. Whereas the left ventricle never varies in size under any conditions, the right heart, as shown by the area of cardiac dulness becomes dilated with the greatest ease and rapidity. The liver which is persistently enlarged fluctuates somewhat in size in accordance with the state of the right heart, but even when at its smallest always extends from two to three inches below the inferior costal margin, no matter how vigorous may be the onslaughts upon it by means of Epsom salts. This patient's symptoms are not of the digestive organs, but are those of shortness of breath and a rapid, pounding action of the heart and general weakness. The urine remains fairly abundant and the menses are too profuse and protracted. She is always promptly benefited by absolute rest in bed, a milk diet, cathartics and digitalis, although this last never materially slows the heart. When in all such cases compensation finally gives way, the breakdown is complete and irreparable. Symptoms of stasis declare themselves everywhere, but do not differ materially from those of cardiac asystolism from any other cause.

The most interesting class of cases is that in which the clinical features resemble those of a case of atrophic cirrhosis of the liver in its terminal stage. These are the cases of chronic fibrous mediastino-pericarditis, and they not infrequently pursue a latent course for many years, and even after symptoms have set in are not recognized as adherent pericardium until they come to autopsy. This applies particularly to cases in which the pericardial synechia is unassociated with valvular disease. Not only is there chronic engorgement of the liver, but the contraction of the fibrous tissue interferes at length with portal circulation and induces serious symptoms. The patient's attention is first attracted by an increase in the size and firmness of his abdomen. In some instances icterus accompanies or even precedes this increase of girth. At length driven to seek medical advice, it is discovered that he has ascites, usually without edema of the lower extremities. The physician examines the heart and urine, detects no heart disease and discovers no albumin, but perhaps some bile. The case is put down as one of hepatic cirrhosis. The following is an illustrative case: Not long ago I saw in consultation a man, fifty-five years of age, who had been intensely jaundiced for nearly two years and in August, 1900, was tapped for ascites. This had rather speedily recurred, had been reduced by apocynum cannabinum for a time, and had again been drawn off the morning of the day I saw him. He had had articular rheumatism eighteen years before, but had not suffered from any shortness of breath nor other discomfort since. The thin-bordered, dense, slightly granular feeling liver extended in the median line nearly to the umbilicus and from one costal arch to the other, being lost beneath the right ribs just outside the right mammillary line. Owing to the recent paracentesis, the peritoneal cavity was free from fluid and there was no edema. The cardiac area was somewhat increased to the right and downward, the sounds were clear and strong and free from murmurs. The apex-beat was rather tapping in the fifth left interspace within the nipple line, and there was not very well marked epigastric pulsation. In the fifth and sixth interspaces between the apex-beat and sternum, and also in the sulcus between the ensiform appendix and left costal cartilages, a systolic retraction could be perceived both by palpation and inspection. Furthermore, when the patient was instructed to draw a full, slow breath, the right external jugular could be seen to bulge out during the inspiration. This distention was also palpable. Pulsus paradoxus could not be determined. I had no hesitation in making a diagnosis of pseudo-atrophic cirrhosis of the liver secondary to adherent pericardium.

Such cases may run a protracted course and require repeated tappings, and the patients succumb to exhaustion if not to the effects of stasis.

Diagnosis.—Under some circumstances this may be one of the easiest of matters; in other cases, it is one of the most difficult. Diagnosis is difficult, if not impossible, when the sac is adherent to the heart but not to the neighboring structures. The signs then relied upon are inspiratory distention instead of the normal inspiratory collapse of the external jugulars or other superficial veins, diastolic collapse of the cervical veins, known as Friedreich's sign, pulsus paradoxus, a by-no-means constant nor reliable sign, and the detection of cardiac hypertrophy for which no adequate cause can be discovered. When the pericardium is adherent to the chest-wall or diaphragm, other signs are often developed that render diagnosis easy and certain. These are a systolic retraction of one or more interspaces in close proximity to the apex-beat or

of the epigastrium, fixation of the apex so that its gravitation from side to side with the turning of the patient's body or its descent during inspiration is prevented, or much restricted, a systolic retraction followed by a diastolic rebound of the chest-wall that by some authors is considered pathognomonic, a systolic sinking or drawing-inward of the tenth and eleventh intercostal spaces below the inferior angle of the left scapula and occasionally of the right, known as Broadbent's sign. These are all very significant and much more frequently discovered than are those previously mentioned. In some instances auscultation detects friction sounds of a fine crackling or creaking character along the sides or apex of the sac, which sounds are synchronous with cardiac contractions and are sometimes elicited only during inspiration. A fine, creaking sound is heard in some cases at the base of the heart upon the body of the sternum while the patient slowly raises and lowers the arms. The detection of such pleuro-pericardial or even strictly pleural friction sounds furnishes indirect or corroborative evidence of the existence of an adherent pericardium, and taken in connection with cardiac hypertrophy and hepatic engorgement would render the diagnosis extremely probable even in the absence of other more distinctive signs. Finally, in some cases in which positive signs can not be obtained, the diagnosis of this condition is rendered possible by a process of exclusion, together with the history of a previous rheumatic attack and the discovery of an hepatic enlargement for which no other predisposing cause can be ascertained.

The elaboration of this subject as well as the prognosis and treatment will have to be left to the speakers who follow.

CLINICAL FACTS AND THEIR MEANING.[1]

BY JOSEPH M. AIKIN, M.D.,
OF OMAHA, NEB.

THE members of this Society are daily confronted with clinical facts demanding solution. He is the exception among us who has the time or facilities for the study of pathology. The laboratory makes superior microscopists and pathologists, but it cannot produce a clinician. Clinical facts seen and their meaning apprehended bring us at once to the rational treatment of our cases.

In dislocations, fractures, or suppurating wounds, the dominant symptoms are common knowledge, the diagnosis usually obvious, and the plan of treatment intelligently indicated by the attending physician.

The busy physician possesses a similar appreciation of the great bulk of his surgical, obstetrical, gynecological, or febrile cases, confidently applies the remedy and the results warrant the confidence reposed in us, to the exclusion of modern "pathies," by the public in treating that class of disorders.

Clinical facts easily seen in the physical organism that are amenable to surgical and medicinal measures are usually presented by their possessors to the regular family physician, who is capable and does give them satisfactory treatment. Centuries of observation, verified by modern bacteriological and pathological research, have given us indisputable right to pre-eminence as leaders in this department of medicine.

The ocular evidence of a successful result, even in minor surgery, speaks more to the non-professional in estimating medical progress, than volumes on neurological or bacteriological discoveries.

The greatest benefits gained through our society meetings must be by comparison of clinical facts in that department of practice demanding our most frequent attention. I believe each member of this Society in his every-day practice, sees more cases classed as nervous than the sum of his cases in any two other departments of medicine. Many times the presence of neuritic complaints do not arrest our careful attention till their magnitude demands thoughtful, active and scientific treatment.

The clinical symptoms leading up to a fully developed motor or sensory paralysis or irritation; a single or multiple neuritis; a case of nervous prostration; neuralgia of the face or stomach, are quite as frequent and positive of some existing disorder as the prodomata in continued fevers, exanthematous affections, diseases of the liver, kidneys, lungs, ectopic pregnancy or uterine fibroid. Neuralgia, cephalalgia, cardialgia, or any of the many sensory nerve irritations common to both sexes, are certainly very frequently the specific cause for complaint by our patrons. If the patient be a male who refers the sensory disorders to the abdominal or pelvic regions, we carefully analyze the whole series of symptoms hoping to find an appendicitis or gall-bladder affection, but, failing in this, we honestly tell our patient so, remarking incidentally, to assuage our own and our patient's disappointment, that the pains are of reflex origin probably due to over-exertion or eye-strain. The favorite tonic prescription and a good prognosis end the interview.

If the patient be a female, the field for surgery is so broad and inviting that tonics and Nature pale into insignificance before the modern, rapid-acting operative procedure as a specific for all imperfectly-defined nervous complaints.

I believe experience justifies the assumption that seventy per cent. of all cases of sickness will recover without medical attendance. I also think a very large percentage of the cases we attend, apart from surgical or infectious disorders, are ill because of faulty digestion or assimilation. The variety and degree of pain and nervous disorder consequent on acute gastric indigestion are generally conceded as sufficient cause for great prostration. Nature is most beneficent and repairs the effects of over- or improper ingestion of alimentary substances, but the limits of toleration are readily passed; especially by those who bear the

[1] Read before the Nebraska State Medical Society, 1901.

burden of an hereditary weakness in digestive powers; beyond this point it is impossible for the natural digestive powers to dispose of this ingesta; destructive instead of constructive metabolism ensues, and the results are either temporary or permanent nervous disorder.

I have associated pain with acute gastric indigestion because sensory impressions are usually more pronounced in stomachic than intestinal disorder, and there are but few patients who think of a digestive disorder in the absence of pain in that organ. That they desire and partake of an abundance of food with but little gastric discomfort, justifies their conclusion as logical, and many times dissuades the physician from even suspecting intestinal indigestion, as the primary and continuous cause of the multiple neurotic and mental complaints he is called upon to treat. At least eighty per cent. of our population have faulty digestion and of these seventy-five per cent. are gastro-intestinal, principally the latter.

The gastric disturbance subsides under stomachic treatment, and after the ingesta have passed into the bowel there is a lessening of the gastric fermentation with much relief, until the patient declares that he is almost free from indigestion; but is continually constipated, resorts to purgatives, is annoyed occasionally by piles, is seldom free from pruritus ani, and is so nervous he becomes apprehensive of grave results. When the meteorism extends into the small bowel, it causes varied sensory impressions. Cathartics, laxatives and tonics are given after improper ingesta, until overstimulation of the digestive organs causes deterioration that may be permanent.

These clinical facts, so numerous when presented to the family physician, are too often passed over carelessly in search for some organic lesion. In medicine as in any vocation negligence of the minor complaints soon produces greater disorders, and we are largely responsible for creating a fertile field for extremists in the opposite direction to adopt some "pathy" as the remedy, while relieving the overworked and overstimulated alimentary canal until Nature restores constructive metabolism.

A very large percentage of our neurotic cases are of purely functional origin. It is, however, as necessary for us to apply rational therapeutics in these, as in treating self-limited febrile or exanthematous disorders.

Every physician of experience in families has seen patients complaining of migratory pains, radiating from the cardiac or post-gastric region, frequent urination with functional weakness of the bladder, cold extremities, flabby muscles and diminished reflexes. The introduction of iron, quinine, strychnine, arsenic, cod-liver oil and other good reconstructives does not in the great majority of cases effect the desired results. Patient and physician are alike discouraged because the strongest medicines fail to cure. Is it any wonder when the digestive canal has been refusing to assimilate natural ingesta? The rational meaning of such clinical evidence certainly points to restricted alimentation. Rest to the overworked organs is imperative. This is best accomplished by liquid diet which serves the double purpose of nutrition and elimination. So far as possible all food should be hot when taken, for its stimulating effects. The amounts ingested at any one time should be below rather than up to the demands of satiety by the patient. The intervals between feeding should be long enough to allow the organs sufficient rest before taking additional food. On the question of frequency of feeding, I am persuaded by practical results that our experience in nourishing fever patients every two or three hours has caused us to follow the same plan in our atonic dyspeptic cases. It is true the vitality is low in either condition, but with a febrile state the fuel is consumed much more rapidly than with a normal or subnormal temperature, so often found in the class of cases we are now considering. The circulation too is slowed and wanting in force. The correctness of this reasoning is proved by my own experience in treating a large number of nervous cases which we all concede should have tonic treatment.

Our failure of satisfactory results in treating illy-defined nervous complaints (where the disorder is most certainly functional) may be discovered in our neglect to use rational means in overcoming the impoverished blood and vitality, the essential symptom of which is malnutrition. A few hours or days will develop the objective facts upon which we base our opinion accounting for the sensory disturbance preceding exanthematous and other acute diseases.

If the overworked, overstimulated, and impoverished sensory nerves cry out with pain, the reason for the sensory disturbance is quite as plain and no less logical than that which we assign for pain during the pyrexia of a continuous fever, congestion of the lungs, or a simple furuncle. Rapidity of progress and the brief lapse of time between successive symptoms in acute cases enable patient and physician to keep the whole clinical picture clearly in view.

To met these conditions, quickly acting remedies of intense combative powers, radically applied, are sometimes immediately imperative. If the destructive agent is virulent and active, rational medicine must exhibit an equally potent opponent. If the ptomain needs weeks and months to establish the changes in metabolism necessary to disturb the sensorium, the rational plan for restoration to normal physiological function is rest, nutrition, and elimination, instead of powerful stimulation and continued overwork of the nutrient vessels.

A drug of sufficient strength to dissolve an hepatic or cystic calculus *in situ* would scarcely be less rational than much of the combative medication and feeding that we impose on an already exhausted nervous system.

The nervous system is slower to recover waste than any other structure of the body, because nerves are less fully supplied with blood-vessels

than any other tissue of the body. The clinical evidence of sensory nervous disorders is quite as plentiful and no less certain than the rational symptoms leading to operative measures in a surgical case.

The perception of these clinical indications belong in the practice of rational medicine; then is it not better that the emphasis be placed at once on the most obvious etiology and its removal instead of treating the symptoms? Every physician present has seen children in convulsions and adults unable to walk erect because tension on the abdominal muscles causes pain. The child is relieved by an emetic, an enema and a dose of castor oil, for it is an acute condition demanding heroic measures. The adult is the child grown to a chronic state with multiplied "algies" and "ites," demanding less radical but more prolonged restorative measures to reconstruct impaired physiologic activities.

Dr. Turck of Chicago in his excellent essay, "Motivity of the Stomach," calls attention to overwork or abuse of the stomach. He says: "Muscular weakness and resultant dilation of the stomach may also be produced by excessive weight, bulk or improper quality of food, or too frequent meals.

"To these factors may be added disturbances of the vascular or nervous system, especially disturbance of the vagus and other pathologic conditions which impair the muscular power of the stomach." Who of us has not seen "heart specialists" consulted for a purely gastric disorder? Among symptoms due to toxins, may be mentioned nervous disorders of all kinds, headache, vertigo, visual derangement, asthmatic attacks, tachycardia, dyspnea, tetany, agaraphobia, etc. A given quantity of food representing and imparting certain nourishing value, shows marked variation when motor insufficiency is present. The diet lists presenting certain foods and their period for digestion are made up from results in a healthy stomach. The regular meal may remain in part undigested not only hours but days, and becomes a source of intoxication rather than nourishment to the patient who with large ingesta of nourishing food, is practically starving, motility is impaired, and the sensory nerves cry out with pain.

It has been well said by Abernathy, "We live on one-third of what we eat, and keep the other two-thirds at the peril of our lives."

AN EPIDEMIC OF SMALLPOX AT THE MICHIGAN ASYLUM FOR THE INSANE, KALAMAZOO.

BY ARTHUR MAC GUGAN, M.D.,

OF DENVER, COLO.

ANY disease appearing in the orthodox form as described in text-books is, as a rule, easily identified and presents little basis for contention. The cases of smallpox occurring in Michigan at present lack some of the characteristics of *variola vera*, but are genuine nevertheless. The epidemic, as it appeared at this institution, is said by those who have seen cases in other parts of the State to present the characteristics common to all and is apparently like some of those reported at the last meeting of the American Medical Association. Being like them atypical, its detailed description would seem, especially at present, to be of use.

On Wednesday, June 11, 1901, I prescribed for a nurse complaining of discomfort incident to the menstrual period. Thursday evening, June 12th, she was excused from duty, her symptoms having increased in intensity. Friday, June 13th, I found her in bed with a temperature of 103.8°F. She complained of intense headache, backache, tenderness all over the abdomen and especially in the epigastric region. No diarrhea nor vomiting. Saturday evening, June 14th, she had a few maculæ on the abdomen and the temperature rose to 106°F. Diazo-reaction and the Widal test negative. She gave a history of epistaxis a week before and I diagnosed "probably typhoid." Hydrotherapy had already been instituted, but, to my surprise, did not materially affect the temperature.

On Friday another nurse was taken ill with the same symptoms, but with absolutely no prodromes and on Sunday, June 16th, both presented an eruption upon the face. The temperature of the first case dropped to 99° F. plus and the other symptoms abated. I saw that my diagnosis of typhoid was wrong and became suspicious of variola. Another member of the staff who had seen and treated some of the Upper Peninsula cases was called and was inclined to the diagnosis of variola. We vaccinated both the patients, also ourselves and gave orders for the usual precautions. Consultation, including the City Health Officer, was called on Thursday, June 18th. By this time another nurse was taken ill with the disease, also four patients. The stage of invasion in all of them was lighter than in that of the first two. It was diagnosed "chicken-pox."

By the end of the second week in July there had been twenty-nine cases, two of which could be called severe. On July 18th, the Health Officer and another physician from the city visited the patients, and it was decided to report the epidemic to the Secretary of the State Board of Health and ask for expert counsel. Dr. George E. Ranney of Lansing was detailed to see the cases and on looking them over pronounced them all smallpox. The institution was at once rigidly quarantined, and a general vaccination begun, which on account of delay in securing vaccine, consumed nearly a week for the 1,700 people. During the week new cases appeared at about the rate of three daily. Since the vaccination only six cases have appeared, all of them having been exposed previous to the vaccination and having the stage of incubation probably established. The last case appeared August 9th and is marked recovered

[1] Read before the Kalamazoo Academy of Medicine.

August 20th, so that the institntion is now free from the disease.

The origin of the epidemic was for a time doubtful, but the contagion is now believed to have been conveyed by a patient brought from the Kalamazoo County House, where there had been a case similar to ours, and several cases with one death subsequently. Unfortunately the patient from the County House died six days after admission and had not developed the eruption. It is possible that later developments may show that the disease reached us in some other manner.

In any epidemic characterized by atypical features one is hopelessly at sea, if he has had no actual experience with the disease and depends upon standard authors for diagnostic aid. This has never before been so clearly borne in upon me as in the present instance, and I think that an account of this epidemic, confined so far as possible to a consideration of such features as do not conform to text-book description, would be of the most value to the average physician.

I shall describe, then, in detail only, Case II., previously alluded to, which conformed more closely to the text-book description, and then proceed to the consideration of what I must regard as unusual features.

Three of our cases were semi-confluent on the face, all the others were discrete. This case, although discrete, was more severe in every way than any of the others. As before stated, she was taken suddenly ill and went off duty Saturday, June 15th. She had a temperature of 103.2°F. which rose later in the day to 105.2°F., complained of pains throughout the entire body, principally in the head and back. There was a slight chill late in the day, some nausea, vomiting and sore throat. June 16th, temperature ranged as high as 106.1°F., and was unaffected by ice-packs or the full bath at 60°F. There was pain in the epigastrium and at night some tendency to delirium. Diazo-reaction and Widal test negative. June 17: Slight eruption appeared this morning, one or two spots on the hand and one or two on the face. Temperature dropped suddenly to 102.8 F. and later in the day to 99.6° F. All other distress disappeared with the exception of epigastric pain which persisted a few hours longer. The eruption rapidly spread over the face, hands and greater part of the body, and on June 18th was vesicular. June 20: The face showed some edema and there was beginning conjunctivitis. The eruption caused some pain, otherwise the patient was comfortable. June 22: The eruption was very painful and the pustules were fully distended. They were opalescent in color and apparently at the height of their development. The course of the eruption was, first, discrete maculæ which later became papular, then vesicular, and toward the seventh day pustular. Some of the pustules were ⅜ inch in diameter and frequently they were umbilicated. They conformed in almost every way to the standard description, excepting that they could be ruptured with little effort, and, although as papules they were hard, consultants who examined them did not think they could be called "shotty" in character. Nor was I able to satisfy myself that any of them were multilocular. There were about 225 pustules on the face, neck and ears. On this day her temperature was 101.8°F. This case with one more were the only ones giving the secondary temperature. The eruption dried quickly, leaving no pitting, and the patient returned to her nursing duties in two weeks. No sequelæ of any kind have been observed. The vaccination done on the day of the appearance of the eruption gave some signs of "a take," but could not be considered typical.

The following cases are rather interesting by reason of their rarity.

Relapsing Variola.—Case XI., insane patient, was taken ill June 24th with the usual prodromes and three days later presented the typical papules on her face and hands. They became pustular and finally desquamated. She was classed as one of the lightest cases. On July 3rd she was taken ill again with a high fever, severe headache, backache, sore throat and two days later developed the eruption, beginning on her face and hands again, but this time covering the entire body. It was much more virulent in every stage of its course and in every one of its features than was the first attack.

Case XXXII. was also of this type. She was taken ill July 16th, nauseated, vomited, headache, backache and gastralgia. Fever was moderate, but her symptoms in general were light. Two days later she developed the eruption on her hands, over the back and lastly on her chest and face. Her case was classed as a light one. She was considered recovered July 24th. In the first week in August she was taken ill again with an initial attack of appendicitis which was treated medically and as her symptoms from this subsided she developed the pain, headache and backache of variola, and on August 7th the characteristic eruption appeared, but not in a more severe form than that of the previous attack. She had not been vaccinated until after the eruption of the first attack appeared.

I know that some are skeptical as to relapsing variola, but there is absolutely no doubt in my mind that such cases occur. Dr. W. De Lano, Health Officer of the City of Grand Rapids, who examined our cases, states that he also has had this year three cases similar to these and has heard of them in the practice of other physicians in the vicinity.

Variola; Second Attack.—Of this we had one case. Case XXVIII., nurse, was ill with variola in 1893 and there are several pits on the forehead still plainly visible. She had never been vaccinated. On July 15th she complained of general pain throughout the body, headache, sore throat, fever, nausea. One day later the eruption appeared on her face, chest and hands. It was discrete, but very well distributed and of medium severity. She was off duty twelve days and re-

ported that she had not felt so ill at any time as she did during her attack of 1893.

Variola Sine Eruptione.—Of this we had two cases. The first, that of the writer, is Case XXVII. July 14th the patient felt tired all day and toward evening noticed severe lumbar pain, which was thought to be due to a scuffle of a few days before or possibly to rheumatism. One or two full doses of salol were taken. At about 5:00 P.M. some faintness and nausea were noticed with cyanosis of the lips and finger-nails, but this was attributed to salol. In the evening there was a slight chill and then high fever which with increasing headache and backache persisted all night in spite of hydrotherapy. At the end of twenty-four hours there were one or two maculæ on the back and during the second day one appeared on the face and one on the hand. None of these became papular and all receded from view twelve hours after their appearance. Had been vaccinated with moderate result in June.

The second case, nurse, Case XLIX, of the epidemic, had been exposed to the smallpox and not successfully vaccinated. On Friday, July 26th, headache and backache appeared. The next day these symptoms were all aggravated. There was intense pain in the epigastrium and fever rose to 105.6° F. Sore throat was present on the third day. The fever began to subside on the fourth day, on the fifth was down to normal and no eruption had appeared. In two days more she was considered recovered and returned to duty. This case presented all the symptoms noticed in the average case and in my opinion was undoubtedly one of variola.

I shall now pass to the consideration of the peculiarities of the epidemic as a whole.

The Period of Invasion.—Curschmann,[1] Osler[2] and Whittaker[3] all speak of chills as being a prominent symptom. It was present in but thirteen of the fifty cases we reported. The fever is described by the same authorities as ranging from 103° F. to 104° F. In 15 of our cases, including some of those of the lightest eruption, the temperature was over 104° F., several over 105° F. and 2 reached 106° F. Almost all the authorities speak of backache as being a constant symptom and headache the next most often observed. Not one of our cases escaped the headache, while 90 per cent. reported backache or diffuse pains throughout the body. Sore throat was not a comparatively frequent symptom, there being 17 cases out of 50 in which it was present. Nausea was present in 14 and epigastric pain in 10. In spite of the high fever there was practically no delirium. The case just described was the only one presenting any such symptom.

The Eruption.—In orthodox smallpox as described by the authors previously quoted, the eruption is supposed to appear on the third day. In 30 of our cases it appeared before the end of the second day, in 5 on the first day, in 10 on the third day, in 4 on the fourth day, and one presented no eruption. Its location conforms to the usual description, appearing in 37 cases on either the face or the extremities first; in 9 on the ventral surface of the trunk and in 3 on the dorsal surface. It appeared in the throat in two and was observed quite generally on palmar surfaces. The early appearance of the eruption is said to be typical of varioloid, if indeed we accept such a term at all. Authors, however, who describe varioloid report a mild stage of invasion. Of our cases this certainly could not be said as with almost all of them was it remarkably severe.

The pustule itself may be said to be peculiar by reason of the fact previously noted that it often broke down easily and furthermore was unilocular, this latter point being one especially insisted upon everywhere as a reliable means of diagnosis between varicella and the vesicular stage of variola. In none of our cases did the pus exude from the pustule anywhere. Serum exuded from the top of the pustule, but never from the base.

Desquamation was a rapid process and in not one case, even in the semi-confluent ones, has there been any pitting. Attempts were made to remove pustules for sectioning with hopes of demonstrating the fibrinous partitions, but these failed, as in every case the only attachment found was that in the center producing umbilication. They all, at maturity, contained pus.

Microscopical examination of the pustule contents confirms the findings of Pfeiffer[4] referred to in the "American Text-book of Theory and Practice," and whose work forms the basis of recent investigations of Funck.[5] We have examined the pustule contents by his method in seven of our cases of variola, also the vaccinia pustules of two or three and a few tubes of vaccine, the characteristic organisms being found in all. It seems to me that this method of differential diagnosis could be made valuable, but I shall allude to it no further here as our investigation has not been carried far enough to justify a definite statement.

Vaccination.—Out of fifty cases reported, 17 had been vaccinated, but none of them recently. I am unable to state either, in the case of insane patients, whether or not the vaccination had been called a successful one. With some of them the scar was barely visible. Of those 17 cases, 3 had the eruption in its severest form, 3 medium and 11 light. Four of our cases, Cases XLV., XLVI., XLVIII. and L. had all been successfully vaccinated during this epidemic and with or following the development of the vaccination pustule the characteristic eruption of variola appeared. In the first case it was diagnosed as vaccinia eruption, but every one of the four followed the usual course of the other cases. In two or three of those the pustule on the site of vaccination may have arisen from the variolic infection. The imperfect vaccination sometimes described as the "mulberry" sore seems to confer a slight degree of immunity, but certainly not absolute. Several of our cases including that of the writer and another member of the medical staff demonstrated this.

Eight cases of different grades of severity in which there had never been vaccination were vaccinated after recovery from variola. No reaction.

Contrary to expectation we had not one infected arm among 1,450 insane patients. The only precaution we were able to take against this complication was the application of a homemade shield, which protected for a few minutes, a few hours or longer, depending upon the caprice of the wearer. A few of the employees had what were apparently infected sores, the cause of which has not been determined, as the same vaccine and the same method was used for all. With the exception of a few re-vaccinations we used the tube.

Other Observations.—There have been no sequelæ and no serious complications. Four of our cases complained of stranguary and were catheterized, 4 of dysphagia, 3 had severe conjunctivitis, in one there was a pustule on the conjunctiva, and in 2 there was a slight roughening of the cornea. All of the recoveries have been prompt.

There were no noteworthy heart symptoms, the only change being that due to the initial toxic state. There was no enlargement of the liver or spleen, and no symptoms referable to the digestive tract, excepting the initial gastralgia or occasional nausea and vomiting. Examination of the urine revealed nothing new or important. The diazo test was made in several cases both at the height of the fever and at the height of the eruption, but with negative results. Some of our insane cases were clearer, mentally, in or following the period of invasion and all, both nurses and patients, seem and profess to be feeling better than before the illness.

The treatment was begun with a few divided doses of calomel followed by saline. Plain milk or malted milk diet was given during the febrile period. We used no medicinal febrifuge, depending entirely upon cold water; the bath, pack, the moist girdle, throat and head compress, depending upon the case. During the period of eruption, the patients were sponged frequently with a 1:2,000 bichloride solution, and during the few hours when the pain was severe from distention of the pustules, the hands and face, which were the parts complained of usually, were covered with a few layers of gauze kept constantly wet with cold soda bicarbonate solution. As the eruption begun to dry it was anointed in the first cases with carbolized vaseline. In the latter cases we used ichthyol with enough lanoline to give it consistency. The application of silver nitrate and of pure carbolic acid to individual pustules was tried, but without any remarkable result. Our severest cases wore no bed-gown and were covered with one sheet only. Everything about the patient was kept scrupulously clean. Great care was taken with diet and bathing.

It is considered worthy of mention that in an institution of this size, the infection did not spread to the surrounding community. We know of no case in the city being traceable to this point and only two cases outside of the city. In both instances the epidemic went no further. Also, that the epidemic was checked so promptly as it has been here, there having been as is shown by the table only six cases since the vaccination, and finally the fact that although most of those affected were insane we have had neither pitting nor complications.

RECTOCOLITIS.[1]

BY WILLIAM M. BEACH, A.M., M.D.,
OF PITTSBURG, PA.;
SECRETARY OF THE AMERICAN PROCTOLOGIC SOCIETY.

By the term rectocolitis, I mean a condition of the rectum and colon that generates functional derangements consequent upon varying degrees of inflammation of its mucous membrane.

The importance of the subject cannot be overestimated since it is known how significant are its symptoms, extensive its reflexes and difficult its treatment. To consider properly the treatment of chronic rectocolitis it is necessary to note briefly, at least, the structure of the organ involved, pathology and symptoms.

The anatomic elements to be noted in this connection are (1) the gut itself, (2) its auxiliary structures. The colon from the cecum to the levator ani muscle is a tortuous, mobile tube of varying caliber, consisting of four coats and anchored to fixed points by a mesentery. The mucous membrane consists of epithelium upon a basement membrane in which exist inverted depressions lined with columnar epithelium, and known as the glands of Lieberkühn, with here and there a solitary follicle—all for the purpose of supplying a lubricant to facilitate the passage of feces. The surface has powerful absorbent properties. The submucous coat is a carrier for vessels and nerves, the muscular coat, circular and longitudinal, is the source of the peristalsis, this in turn is covered by the peritoneal coat which serves as an anchor. The colon is surmounted along the greater part of its length by two or more fibrous bands, by its axis which gives it a sacculated appearance. These bands are said to be composed of the longitudinal muscular fibers and are called teniæ.

The auxiliary structures consist of the blood- and nerve-supply, the proper consideration of which will clearly demonstrate the cause of many reflexes that follow in the trail of pathological change in the rectum. The blood-supply to the colon is derived from the superior and inferior mesenteric arteries. The veins from the different portions of the colon join the inferior and superior mesenteric branches of the portal system. The rectum has a special blood-supply from three

[1] Read before the American Proctologic Society, St. Paul, 1901.

diverse sources—the superior rectal from the inferior mesenteric; the middle rectal from the anterior root of the internal iliac; and the inferior rectal from the internal pudic artery. The rectal arteries pass parallel to one another toward the anus, and freely communicate by large transverse branches. The veins are similarly arranged, and form the hemorrhoidal plexus about the lower end of the rectum. The main trunks from the latter are the superior hemorrhoidal veins, tributaries of the inferior mesenteric vein, and the middle and inferior rectal veins which terminate in the internal iliac veins, so that the portal and general venous systems intercommunicate. To this fact is chiefly attributed the tendency of the anal veins to become varicose and to the formation of piles; and a further contributing factor is an obstructed portal circulation arising from a torpid or diseased liver. The colon and rectum are well supplied with lymphatic vessels, so that it is readily understood how easily patients may suffer from the absorption of ptomains through a diseased mucosa, made so by fecal residue retained by obstructed passage.

The nerve-supply of the colon is derived from the superior and inferior mesenteric plexuses of the sympathetic system. The nerves of the rectum are derived from the inferior mesenteric, hypogastric, and sacral plexuses. So that peripheral irritation due to rectocolitis may be reflected to distant points and organs, as well as various other pelvic organs, as urethra, ovaries, uterus, vesiculæ seminales.

We may consider rectocolitis in any of the following stages, omitting malignant diseases: (1) *Congestion;* (2) *atrophic catarrh;* (3) *hypertrophic catarrh*; (4) *ulceration.*

Simple congestion due to engorged blood-vessels may be ephemeral in duration and express itself locally in the form of dysentery and tenesmus, the glands becoming excited and developing an enormous quantity of mucus. Of course, if this condition continues, it becomes chronic, developing usually the hypertrophic catarrh; the epithelium is shed, the valves are swollen and thickened, plastic material is thrown out with consequent narrowing of the rectal straits, and there is diarrhea alternating with constipation.

Atrophic catarrh, on the other hand, is usually accompanied by the constipated habit—a dry, hard stool and minute anal fissures; secretions are insufficient on account of gland impairment. Atrophic rectocolitis is rare.

The ulcer is the culmination of the inflammatory process, but, I believe, rarely occurs above the sigmoid flexure; in other words the process rarely goes beyond the catarrhal stage. The points of predilection for ulcer are the cecum, flexuses and rectum, but clinical experience teaches me that, for the most part, the disease is confined to the sigmoid flexure, since that region is the reservoir of the fecal contents in course of expulsion. Owing to the peculiar and extensive blood-supply, the rectal mucosa is prone to congestion and inflammation; and it is not improbable that all the coats of the bowel may be involved, extending to the peritoneum.

The symptoms of rectocolitis are (1) local or physical and (2) constitutional or rational. In acute dysentery or "bloody flux," large quantities of jelly-like mucus, with blood, appear in the stool, accompanied by severe straining and tenesmus. Chronic hypertrophic catarrh produces shreddy casts of long or short pieces that are sometimes tinged with blood, stools irregular, etc. Inspection reveals thick and rigid valves, their margin at times denuded of its epithelium, red and inflamed, and the touch of an instrument evokes severe pain in the back according to the nerve-center disturbed. For the same reason the symptoms of rectocolitis are referable to the uterus, mouth of the urethra, ovaries and stomach. Constitutional symptoms occur through the absorption of ptomains from retained feces and gas, which results in severe and constant headaches, especially post-cranial and cervical, nausea, anorexia, fermentations, pains in back and vague pelvic and abdominal discomfort; the patient tires easily and is greatly depressed; the extremities are cold; the pulse is weak, indicating great nervous exhaustion; in short, the patients become confirmed neurasthenics. However, their physical appearance is that of good health; hence, they derive little sympathy from their friends.

From the standpoint of the proctologist, is rectocolitis curable? To answer this question, we must bring to bear our clinical experience. Tuberculosis, syphilis and rheumatism as causal factors are excluded from this discussion, as we wish to limit our consideration to the catarrhs of local origin—as from constipation, fistula, hemorrhoids, polypus, and disease of the rectal valves. Mathews has cured rectocolitis due to a submucous fistula five inches up the rectum. Bodenhamer has cured the disease by the simple removal of hemorrhoids. Martin has obtained satisfactory results by removing intrarectal obstructions. Others have reported cures from high injections of hot water, oil or various antiseptics and astringents, as iodoform, boric acid, hydrastis, krameria, nitrate of silver, etc. And yet there are cases that resist any of these measures, except as a temporary relief.

I believe many patients can be cured by such measures, but there is one type to which I would especially call your attention, namely, congenital or functional narrowing of the rectosigmoid strait. In many of these cases the spasm is so strong when the instrument touches the inflamed surface that the strait is entirely closed; in others there is prolapse of the sigmoid, and a great deal of dexterity is required to pass an applicator, and then to the great distress of the patient. In February last a neurologist sent me a patient whom he had been treating for spinal irritation for some time, believing he had some rectal trouble. Examination revealed piles and proctoscopy a very sensitive rectum covered with glairy mucus, the sigmoid strait narrow and spasmodic with great pain at the upper part of the sacrum. I

have treated him twice a week since, with the result of marked amelioration of headache and backache. In this class of cases I begin with a daily administration of a saline, preferably Apenta, a half-tumblerful given at night. Once daily a large injection of hot water; then through the proctoscope I mop the entire surface with sweet oil, and through a narrow tube attached to a Davidson syringe I throw a half-pint into the colon while the patient is in the Martin posture. This is continued for from one to three weeks, or until the peristalsis and tenderness subside, when I substitute for the oil mildly astringent solutions with rectal massage. The atomizer is a useful instrument for making these applications. Massage with a divulsor of two blades should be practised from every third to fifth day, in order to reduce the valves, to be followed by the spray. Various remedies are suggested, such as nitrate of silver, 3 grains to the ounce; albolene and hydrastis, equal parts with water; but I find in protargol, 15 grains to the ounce, a sovereign remedy.

Rectocolitis due to mechanical obstruction or irritation, as a retroverted uterus, pelvic adhesions and tumors, can only be relieved by removal of the cause. Obviously the first indication in the line of treatment is to remove the débris, the product of the inflammatory process in the form of membranous casts, mucus, etc.; in other words, clear the field of operation as far as possible, so that the remedies locally applied may be efficacious. Abrasions and pin-point denudations of epithelium should be touched with pure carbolic acid or solution of silver nitrate. This treatment is usually followed by a profuse discharge of mucus and at times some blood is passed. If, however, the mucosa presents a deeply injected appearance, bland remedies, I believe, are more efficient, such as the oils—albolene, for example, sprayed over the entire surface. I have had patients express the most profound satisfaction following such an application, which relieves all the reflexes.

When the rectum becomes more tolerable to instruments, I use a two-bladed divulsor wrapped with cotton, for the purpose of reducing valvular hypertrophies, and thus relieve the obstruction, for those patients usually suffer from coprostasis and retention of gas.

To correct the intestinal secretions and allay neurotic symptoms, resort must be had to certain internal medication. Though the nervous element is secondary to the rectocolitis on account of poisoned nerve-centers by auto-intoxication, it becomes the object of special treatment. Depurative and sedative agents must then claim our attention. Anemia usually accompanies rectocolitis of long standing. For the altered secretions, some salt of mercury stands pre-eminent. Legitimate associates are cascara sagrada, podophyllum, stillingia and rhubarb. Minute doses of blue mass, ⅓ grain, or bichloride of mercury, $^1/_{10}$ grain, before meals, are effective with daily doses of Apenta. A favorite prescription to meet the indications of faulty intestinal secretion, nervousness and anemia, consists of the following:

℞ Ferri sulphat. exsic.
Ext. hyoscyam., aa.....3ss
Ext. nuc. vom.
Pulv. aloes.
Pulv. mass. hydrarg., aa.....gr. viiss

Ft. capsules No. 30. Sig. A capsule before each meal.

By relieving the portal circulation, congestion of the rectal vessels would subside. The patient should be put to bed for two weeks and a light diet enjoined, consisting of broths, fish, eggs, lettuce, celery, and rhubarb in season. A daily bath and alcohol rub will promote nervous equilibrium. At the end of two weeks, the patient is not so nervous, can sleep, the appetite is sharpened, his evacuations become more regular, and the quantity of mucus less. Local treatment has been given daily as above indicated. The patient should be free from care and his environment made pleasant as possible. A morning walk and drinking large quantities of water should be encouraged.

Rectocolitis due to polypus, hemorrhoids, fistula or stiff valves is to be cured by the removal of these conditions. Constructive remedies are to be employed, such as strychnine and iron. The prognosis for ultimate recovery from rectocolitis must be guarded, for the treatment may extend over several months and even years, since certain cases resist most appoved measures, both local and systemic. The majority of cases can be cured by the management just outlined.

Conclusions.

1. Rectocolitis is a condition of the rectum and colon of varying degrees of inflammation.
2. A knowledge of the anatomical bearings of the rectum and colon is necessary to understand the symptoms and reflexes.
3. The symptoms are local and systemic.
4. Rectocolitis may be catarrhal or ulcerative.
5. It may be acute or chronic.
6. When dependent upon polypus, hemorrhoids, fistula, etc., the cure depends upon their removal.
7. Chronic rectocolitis due to altered secretions, anemia, and congenital narrowing of the sigmoid strait, is difficult to cure.

Home Office Building.

Schede's Operation in Chronic Empyema.—Two cases of serial resection of pleura, ribs and intercostal muscles for the cure of chronic empyema are reported by BOUGLÉ (*La Presse Méd.*, Oct. 30, 1901). The ribs were removed successively from below upward; in one case the eighth, seventh and sixth, each in turn, and in another the ninth, eighth and seventh in one operation and the sixth and fifth afterward. Both patients were cured. Bouglé emphasizes the utility of the U-shaped incision and the necessity for the suppression of the costo-diaphragmatic cul-de-sac.

MEDICAL PROGRESS.

Pathology of Ringworm.—Although ringworm was the first disease to be definitely traced to the action of a vegetable parasite, but little advance has been made with respect to the knowledge of the pathological changes produced. Divergence of opinion exists as to whether keratin is attacked chemically by the causative parasite. W. D. EMERY (*Jour. Path. and Bac.,* Nov., 1901) has investigated the chemical action upon keratin of the *microsporon audouini.* This parasite was selected as being the most common ringworm fungus in England. He shows that this organism possesses no power to digest this substance, to alter its solubility, or to obtain from it the pabulum necessary for growth. Under normal conditions this parasite obtains its nourishment solely from the proteid material present in the hair-follicle and the hair itself. Many factors enter into the causation of the loss of hair in ringworm. By mechanical effect the peripheral fibers of the hair are split off by the spores which have invaded it. The parasite obtains the amount of water necessary for its growth at least in part from the hair, which thus becomes fragile. The fungus exerts a considerable amount of pressure upon those parts of the hair which are contained within the follicle; this operates powerfully upon the hair root and causes an interference with the formation of new hairs. The toxins produced by the parasite set up a folliculitis of a slight grade; this also interferes with the formation of new hairs. It is thus seen that the fungus acts both mechanically and chemically, but that the latter action is not exerted upon the keratin of the hair shaft.

Cardiac Neuroses.—As symptoms of functional disease of the heart, A. PICK (*Wien. klin. Rund.,* Oct. 9, 1901) mentions a moderate struma, involving chiefly the right lobe of the thyroid and without pulsation or thrill, increased irritability of the heart manifesting itself by tachycardia on slightest exertion, dermographia, so that on irritating the skin, pallor, then reddening often lasting two hours and sometimes with urticaria, followed, hypertrophy of the left ventricle, inequality of the pupils, dependent upon dilatation of the right pupil, which however readily reacts to light, anesthesia of the pharynx, increased reflexes, hyperidrosis in the axilla, hippus, tremor of the fingers and the closed eyelids, arhythmia and Erben's pulse phenomenon. This latter consists in a slowing of the pulse on stooping forward, followed after 3-6 beats by an increased frequency. In some of the cases of pure cardiac neurosis examined there was a close resemblance to Basedow's disease, but exophthalmos, Graefe's or Stellwag's sign were never seen.

Pancreas in Diabetes Mellitus.—The probability that the peculiar structures in the pancreas known as the islands of Langerhans play an important part in carbohydrate metabolism has some time since been pointed out. Recent observations upon the pancreas in relation to diabetes mellitus have given this idea strong support. In examining fourteen cases of chronic interstitial pancreatitis Opie found these islands affected in four. In all of these but one diabetes mellitus was present. None of the other ten showed a diabetic condition. The idea generally prevalent at the present time is that, although diabetes mellitus is not always associated with alterations in these islands, such alterations are invariably accompanied by a diabetic condition. In view of the importance of this subject in relation to the pathology of diabetes new observations along this line are of great interest. Such come from JAMES H. WRIGHT and ELLIOTT P. JOSLIN (*Jour. Med. Research,* Nov., 1901). They examined the pancreas in nine cases of diabetes mellitus. From each case a section from one to three places in the gland was examined. Hyaline changes in the islands of Langerhans, similar to those described by Opie, were found in two of these nine cases. The remaining seven showed no definite lesions of the pancreas except one in which an exudate of fibrin and leucocytes was present. Of those cases which showed alterations of the islands in one there was also present a small area infiltrated with polynuclear leucocytes and microscopic fat necrosis. The other was extensively invaded with fat tissue. The changes observed in these two cases are in favor of the hypothesis that lesions of the islands of Langerhans are important factors in the pathology of diabetes mellitus.

Suprarenal Diabetes.—A substance is found in the suprarenal glands which may cause glycosuria if it enters the circulation. This is the statement made by F. BLUM (*Deut. Arch. f. klin. Med.,* Oct. 31, 1901) and based on the results of his investigations on the influence of suprarenal extract on metabolism. His experiments were made on a series of twenty dogs and three rabbits, all healthy animals with no previous traces of sugar in urine. He employed a watery sterilized extract of the suprarenal glands of calves or sheep, injecting the same subcutaneously or intravenously, the former being preferable because less apt to cause complicating symptoms due to extreme rise of blood-pressure. Sugar always appeared in the urine in varying amounts, up to 3.8 per cent, until the death of the animal, and this not only in the total absence of a carbohydrate diet, but also in starved animals where all the glycogen in the liver had probably disappeared. The question remains whether the suprarenals have any influence in the diabetes of the human subject. Glycosuria is undoubtedly due to a toxic effect on those organs which are concerned with carbohydrate metabolism. We may believe that the suprarenals have a function analogous to that of the thyroid gland, the removal of a free poison from the circulation. A total failure of this act might

possibly cause Addison's disease, a partial one glycosuria or diabetes.

Changes in the Pulse in Diseases of the Alimentary Tract.—The relations between stomach and intestine on the one hand and heart on the other are manifold. G. SINGER (*Wiener klin. Rund.*, Oct. 9, 1901) draws attention to the bradycardia of ulcer and ectasia of the stomach, jaundice and typhoid, and the increased cardiac activity, paroxysmal tachycardia, palpitation, unrest and tendency to congestions so often seen in dislocations of the stomach and colon. In chronic constipation and atony of the colon there often is arhythmia and considerable stress is laid upon the occurrence of true intermittence of the pulse in these conditions. All these phenomena are best explained upon the theory of auto-intoxication, especially since the free use of intestinal antiseptics generally removes them.

Acute Intestinal Obstruction following Appendicitis.—The dreary fact that this condition is a late consequence of otherwise successful operations for appendicitis is more and more plain. L. W. HOTCHKISS (*Annals of Surg.*, Nov., 1901) reviews three cases and sums them up in the following terms: (1) The great utility and necessity for the free use of decinormal salt solution injected beneath the skin, into the rectum or into the veins during or after the operation as a guard against extreme shock; two of his cases were probably saved by not only free but continued use of it; (2) the great value of free incision into over-distended coils of gut in order to relieve upward pressure against the diaphragm with its disturbance of respiration and circulation; in order to relieve intestinal congestion and distention so that they can be handled without injury and the obstruction located and removed, and in order to drain away the poisonous, stagnant fluid contained in the gut which would otherwise be absorbed; (3) the wisdom of closing the abdomen without drains and of leaving within the cavity sufficient salt solution to float the intestines and assist, perhaps, in their rearrangement. This much for the broad detail of the operation. The after-treatment possesses three essential features also, as follows: Persistent and intelligent lavage; early and, if necessary, repeated administrations of concentrated saline purges introduced through the stomach-tube if retained in no other way; the relief of intestinal gas by means of the rectal tube and of high enemata patiently, persistently and rationally given. A fourth detail should be named, *viz.*, absolute abstention from the use of morphine. The author states that the above are sure guides through this difficult field in surgery.

Pathology of Pellagra.—In 1864 attention was first drawn to the changes in the spinal cords of pellagrous patients. It was not, however, until 1893 that much light was thrown upon the pathology of this disease. At that time Tuczek demonstrated sclerosis of the posterior columns and columns of Goll in all the cases which he examined. The most recent researches in this disease come from F. M. SANDWITH (*Jour. Path. and Bact.*, Nov., 1901). He examined post-mortem three fatal cases of pellagra. All of these had been pellagrous for some years, but eventually died from other causes, the first of cerebral hemorrhage, the second of a complicating chronic nephritis, the third of acute pericarditis. In the first case there was some degeneration of the posterior columns, as shown by Pal's method. The posterior median columns were unduly pale. The second case showed marked degeneration of the posterior columns which was evidently of root origin. There was an increase of the connective tissue in the area of the affected roots and some thickening in the walls of the arteries. The third case showed practically no change except some slight alteration in the medullated sheath of certain fibers, as shown by the blue black method. That the process is essentially a chronic one is shown by the fact that, although the posterior columns are sclerosed, no degeneration can be shown by Marchi's method.

Congenital Narrowing of the Aorta.—It may be positively stated that a diminution in the caliber of the aorta is a frequent cause of disease, as proved by numerous anatomical and clinical sequences. These have been carefully studied by BURKE (*Deut. Arch. f. klin. Med.*, Oct. 31, 1901) and his results are summarized as follows: (1) Anatomical changes in the (*a*) heart—a left sided hypertrophy, to which may subsequently be added dilatation of left ventricle and auricle, signs of chronic pulmonary congestion, hypertrophy and perhaps dilatation of right ventricle; (*b*) in the arteries—an arteriosclerosis in young subjects as an expression of a long-continued elevation of blood-pressure. (2) Clinical appearances—paleness of face, a feeling of oppression in chest, cough with catarrhal expectoration, signs of dilatation, hypertrophy and insufficiency, expansion of the boundaries of the lungs, a chronic bronchitis, increasing weakness of the right ventricle, enlargement of the liver, albuminuria, general edema. The number and character of these symptoms depend on age, sex, occupation and habits. In women there is apt to be a primary or even a pernicious anemia, whereas secondary changes in the heart are usually absent. Probably the diminution in the volume of blood serves as a compensation for the increased resistance encountered in the aorta. This is not so apt to be the case in men, hence, the picture here of actual cardiac disease. Etiologically, two causes are proposed for this narrowing—it is either a purely congenital condition or else due to a retardation of the aortic system during the growth of the remainder of the body.

Parotid Tumors.—Any point which aids in the clinical diagnosis of any question is worthy of accurate note and probably no class of diagnosis is more difficult than that of tumors. New

growths of the parotid are rather more lawless than elsewhere, says H. T. BUTLIN (*Lancet*, October 19, 1901), but after all present a tendency in common to all rather consistently, which is that the malign always produce sooner or later paresis or paralysis of the facial nerve. Billroth tried to distinguish sarcoma from carcinoma by the fact that the latter produces and the former does not produce such nerve lesions. His error probably consisted in regarding such tumors as sarcoma which to-day are regarded as probably benign, though highly irregular in type of cell-arrangement. Within Butlin's observation the rule holds good that whenever a tumor has affected the facial nerve it has done so by infiltration in contiguity and not by mere mechanical pressure. Such infiltration in contiguity is in accord with the manner in which malign growths spread elsewhere in the body, and hence the deduction is rational that such a sign in the parotid region foretells the cancerous character of the neoplasm.

Pseudoclumping of Typhoid Bacillus.—An ordinary young culture of the typhoid bacillus in broth shows the bacilli all separated and in active movement. All observers, however, who have worked with typhoid cultures have observed broth cultures of this organism which, while showing many bacilli active and free show others arranged in clumps which closely simulate those met with as the result of specific typhoid agglutinins. These are the so-called pseudoclumps and much speculation has been indulged in with respect to the factors which underlie their formation. Some hold that mechanical causes are prominent, in that foreign material to which the bacilli attach themselves is present in the culture. Others have thought that certain products produced by the organisms themselves are responsible for these formations and have therefore reasoned that the "agglutinins" are not the products of the body cells. W. G. SAVAGE (*Jour. Path. and Bact.*, Nov., 1901) has exhaustively considered the subject. As the result of his work it would appear that mechanical factors play no part in the formation of these pseudoclumps. All evidence is against the fact that such are formed through the agency of any product of the bacillus itself. There is marked evidence to show that certain races of typhoid bacilli are especially prone to form pseudoclumps. Such a peculiarity is extremely difficult to eradicate when it is present. Certain peculiarities of the Liebig's extract or meat used to make the broth have an influence upon this formation. The chief difference between pseudo- and true clumps is the absence of all lysogenic action in the former. The practical deduction is that in all tests of blood or serum for the presence of specific "agglutinins" proper controls should be instituted.

Immediate Death Due to Spinal Cocainization.—Without intending to reopen the discussion as to the value of spinal cocainization, a method of anesthesia which he has hitherto practised and advocated, F. LEGUEU (*La Presse Méd.*, Nov. 9, 1901) considers it to be his duty to report two recent cases in which death followed the injection of cocaine into the spinal canal, within a few minutes. The technic, the dose and the cocaine solution used were the same as were utilized with success in cases preceding and following those which were fatal. The cocaine which caused death was analyzed and found to be unaltered. Operation was proposed in one of the two instances for rupture of the patellar ligament, and in the other for strangulated inguinal hermia.

Widal Reaction in Children.—The value of the Widal reaction in diagnosing the presence of typhoid fever in adults is now no longer disputed, but it has been urged by some that the reaction is not so constantly found in children. M. GERSHEL (*Med. Rec.*, Nov. 23, 1901) reports the results on 84 cases of typhoid fever and 115 cases of various febrile diseases, such as meningitis, tuberculosis, pneumonia, endocarditis, etc. In the 84 cases of typhoid, ranging from one and a half to fourteen years of age, 81 cases gave a positive result. In 115 cases of fevers other than typhoid the positive reaction was never obtained. The reaction did not occur later in children than in adults, as is claimed by some writers, but on the contrary somewhat earlier. The reaction is of even greater importance in children than in adults, owing to the frequent occurrence of atypical forms and the greater frequency of cases resembling pneumonia and meningitis. The main facts concerning the Widal in children are the same as those which hold true for adults.

Deductions Concerning Milk Modification.—The main efforts of milk modifiers have been directed to the reduction of the so-called casein, and to the replacement of the fat, which is diminished unduly when the proportion of casein is reduced by dilution. The so-called casein of milk consists of caseinogen in lactalbumin these being found in equal proportions in human milk, but in the proportion of six to one in cow's milk. R. C. MACDONALD (*Boston Med. & Surg. Jour.*, Nov. 21, 1901) suggests that intelligent milk modification must endeavor to raise the proportion of lactalbumin. Again, in cow's milk phosphorus exists mainly in inorganic (mineral) compounds; in human milk phosphorus is found chiefly in organic combination, and, while the inorganic compounds are practically non-assimilable, the organic compounds are readily taken up by the human system. Both the important deficiencies just mentioned can be overcome to some extent by the judicious use of the whole egg; egg albumin quite closely approximates lactalbumin and in the egg yolk there exists a veritable storehouse of organic phosphorus.

Specific Nature of Rabies.—In reply to an article written by C. W. Dulles last July denouncing the theory that rabies is due to a specific germ and that the Pasteur treatment is use-

less, D. E. SALMON (*Med. Rec.*, Nov. 23, 1901) shows the fallacies in the above arguments and expresses regret that a man of such wide experience and so much influence as Dr. Dulles should fail to recognize the truth of scientific investigation. A very important piece of evidence to show the infectiousness of rabies is the fact that the disease has almost entirely disappeared in England since the law compelling dogs to be muzzled has been rigidly enforced. When the enforcement of this law is left to local authorities it is seldom properly accomplished. The history of the disease in England and Scotland is very interesting and valuable. For several years the Board of Agriculture successfully enforced the law in the affected districts and the number of cases was much diminished, but, when each district managed its own affairs and respected too much the individual rights, the number of cases enormously increased to 672 in 1895. The Board of Agriculture again took charge and the number of cases has steadily decreased, so that only six occurred in Scotland and England during 1899 and none in 1900.

Pyopericarditis. — Idiopathic pericarditis probably never exists, inflammation of the pericardium being always a secondary affection. It may be found as a complication of any disease which introduces into the circulation either toxic material or infectious germs, or it may result from neighboring inflammatory lesions, the nature of the exudation depending upon the original cause. In rheumatism and in Bright's disease we find a serous effusion; in cancer of the lung or tuberculosis, more commonly a hemorrhagic exudate; in septic troubles and pyemia pus is usually to be feared. H. O. COLLINS (*N. Y. Med. Jour.*, Nov. 16, 1901) mentions among primary causes of pyopericarditis abscess of the mediastinum, caries of ribs or sternum, Pott's disease, cancer or abscess of the lungs, empyema, cancer or abscess of the esophagus, inflammation of the breasts, and bronchopneumonia in addition to the various systemic septic diseases. In regard to diagnosis the marked dulness in the fifth right intercostal space is of great importance in distinguishing a dilated heart from a pericardial effusion. Four methods of operating have been suggested—aspiration, simple puncture, incision through an intercostal space, and incision with the resection of one or more ribs and drainage. The latter more radical method is undoubtedly the best in all cases of pus in the pericardium, for irrigation and drainage which are essential to cure can be obtained in no other way. The operation has usually been done on the left side, either the fourth and fifth or the fifth and sixth costal cartilages being resected. The pleura and the internal mammary artery are to be carefully avoided. The right side has recently become a favorite site, as better drainage can probably be obtained on that side.

Rapid Anesthesia by Ethyl Chloride.—Anesthesia is obtained in from twenty to forty seconds by a method described by A. MALHERBE (*La Presse Méd.*, Oct. 30, 1901); from two to four grams of ethyl chloride are used. The anesthetic is poured on a simple compress, which is then hermetically applied to the nose and mouth of the patient, all air being temporarily shut out. The narcosis which follows lasts for three or four minutes. If a more prolonged anesthesia is desired the process is repeated. Owing to its simplicity and to the absence of disagreeable sensations ethyl chloride is also used as a preliminary to chloroform anesthesia in operations of very long duration.

Facts Concerning Pleural Exudates.—The prevailing theory in regard to the final disposition of the cellular elements in pleural exudates pictures a process of fatty degeneration followed by absorption of the fatty detritus. A. WOLFF (*Berl. klin. Woch.*, Nov. 11, 1901) shows that this process is by no means invariable. The theory that such a process always takes place arose from the study of unstained preparations; it is impossible to distinguish unstained nuclei of "mastcellen" and eosinophiles from fat droplets. Fatty degeneration of the leucocytes of pleural exudates does however occur; in comparatively fresh cells glycogenic degeneration also takes place, the two processes being in a sense opposed to each other. Both fat and glycogen are derived from the same carbohydrate source.

The Psychoses of Chorea.—Insanity in the course of true Sydenham's chorea does not often occur; at any rate, it is rarely referred to in medical literature. Choreas which are accompanied by mental disturbance later in life are almost always associated with organic changes in the central nervous system. In a majority of cases of Sydenham's chorea, according to H. N. MOYER (*Jour. Amer. Med. Assoc.*, Nov. 23, 1901) a well-marked alteration of character and mentality can be noted some weeks preceding the onset of choreic movements. Mental disturbance of the type of melancholia, mania or acute delirium, usually comes on after choreic movements, but may precede them. Such disturbance is commoner in older children than in those under twelve years of age. The prognosis is favorable when mental disease complicates the simple, acute chorea of Sydenham, unfavorable in the choreas of middle and advanced life on account of the organic changes present.

Ventroscopy by the Vaginal Route.—One of the claims in favor of abdominal section and against the vaginal route in gynecology is the fact that the latter operation affords no chance of inspecting the contents of the abdomen. D. DE OTT (*La Sem. Méd.*, October 30, 1901) seeks to overcome this by placing the patient in what is practically a Trendelenburg posture with the exception that the lithotomy position of the lower extremities is still maintained. With the trunk in this position and the vagina open, with the aid of electric light and tubes he has suc-

ceeded in gaining a very good view of most of the organs of the abdomen. He claims that he has been able to examine as high as the stomach, the liver and the gall-bladder in this manner. The method is ingenious and certainly worthy of trial.

Research of Biliary Acids.—The classical methods for detecting the presence of biliary acids are inadequate to show the presence of these substances when present in small amount in organic liquids. Recently M. G. MEILLERE (*Comptes Soc. Biol.,* Nov. 1, 1901) has shown that minute quantities of these acids can be demonstrated when present in urine by adding one per cent. of sulphuric acid and agitation with a great excess of sulphuric ether, acetic ether or chloroform. When urinary pigments soluble in ether are present it is necessary to remove or decolorize these. This may be accomplished by the addition of ten drops of basic acetate of lead and subsequent treatment with hydrogen sulphide. A decolorized liquid is thus obtained. This process of decolorization may be practised before or after treatment with the ether. In searching for these acids in serous fluids the albumin must be coagulated by heat and the addition of four parts of alcohol together with a few drops of trichloracetic acid. The coagulum is then washed in hot alcohol in order to remove the taurocholic acid which the albumin energetically holds. This is then evaporated and the residue treated as above described.

Genital Tuberculosis in Woman.—An exhaustive thesis on this subject by M. GOROVITZ (*Rev. d. Chir.,* Oct., 1901) is concluded as follows: (1) Genital tuberculosis in woman is much more frequent than was formerly thought. This is proved only by histological and bacteriological examination by inoculation in cases which formerly might have escaped diagnosis; (2) it is often secondary, sometimes primary. In the primary cases it is only by careful examination that the diagnosis can be proved; the disease may affect the mucous membrane of the womb or of the tubes; (3) by clinical facts and by surgical operations it has been learned that this tuberculosis of the tubes excites in the peritoneum more or less active trouble and in particular a special form of inflammation accompanied by the formation of small cysts; (4) it is therefore necessary in opening the abdomen of women who have a tuberculosis peritonitis to examine the tubes and see whether they are or are not the source of the disease; if they are, they should be removed; (5) such removal should always be made by the abdominal route because the extirpation should be wide and the abdominal wound large enough to permit treatment of the disease elsewhere; (6) from the standpoint of origin of the disease it may be said that it may be a descending or an ascending affection, the former being the more frequent; (7) it is clinically proven that infection may be carried by the spermatozoa of consumptive patients; (8) experimental researches show that living tubercle bacilli deposited on a mucous membrane without wounds may easily cause the disease.

Auscultation of the Pulmonic Apices in Young Infants.—The presence of a certain acoustic anomaly in the apex of the infantile lung has been considered by the majority of clinicians an indubitable symptom of incipient phthisis, writes ALFREDO VILLA (*Revista Critica di Clinica Médica,* Nov. 9, 1901). Repeated observations prove that this phenomenon has not always the significance which is generally attributed to it. It has been found that crepitant râles, with harsh breathing, are frequently heard at the apices of infants' lungs if auscultation is practised after a prolonged recumbent position, with the head low. These rôles may be considered physiological and are indications of atalectasis due to imperfect expansion. They disappear when the respiratory function is fully established.

Syphilitic Joint Inflammations.—The diagnosis of this condition is difficult, because the signs of the disease often disappear under treatment. Dr. BORCHARD (*Deut. Zeitsch. f Chir.,* Sept., 1901) draws the following conclusions from his observations: Acute syphilitic joint inflammation, with water and swelling of the capsule, consists in nothing but the evidence it gives of the share the joint proper is having in the general acute infection of the disease. Such may naturally arise whenever the poison has manifested itself with very active secondary symptom everywhere in the body; (2) on the other hand, the more permanent syphilitic diseases of the joints, such as appear in the third period of the disease, must necessarily be of the order of gumma or of chronic productive inflammation; (3) these products have their situation in the synovium, the subsynovial tissues and in the cartilages. The increase in the number of cells is not a consequence of a chronic hydrops or of a fibrinous deposit on the synovium, but is due to the growth of small miliary gummata. These gummata are really the cause of those thickenings of the joints which may often be seen in life. He further believes that an acute hydrops in this disease can, without further cause, become chronic. The cause of it seems to be in such a case always the growth of miliary gummata. Every hydrops in the third stage and in the congenital forms of disease is probably due to the same state of affairs, *viz.,* the growth of gummata in the synovium, the parasynovial tissue and in the cartilage.

The Pest Bacillus and Serumtherapy.—In the artificial cultivation of the pest bacillus it should always be borne in mind that this organism grows best at temperatures below 25° C. The most favorable being between 22° and 24° C. The incubator temperature (37° to 38° C.) should always be avoided as oftentimes no growth is obtained, at this temperature, upon

artificial media. The growth upon potato is characteristic. When grown upon this medium at 15° to 20° C. a greenish-white layer is formed in from four to six days. The above points are emphasized by M. J. LIGUIERES (*Ann. de L'Ins. Pasteur,* Oct. 25, 1901). In regard to serum-therapy, the Roux-Yersin serum has proven very efficacious in his hands when employed in large doses and inoculated intravenously. From forty to sixty cubic centimeters of the serum should be so inoculated and followed in from twelve to twenty-four hours by a subcutaneous inoculation of twenty or forty cubic centimeters. The intravenous inoculation must be practised with great care only slight pressure being used. It must be discontinued if suffocation or cyanosis appear. Preventative inoculations produce no notable reaction.

Surgical Asepsis and Antisepsis.—With the view of determining the value of antiseptics in surgical work, and to what extent asepsis of the operative site and wound could be obtained, GANGITANO (*La Riforma Médica,* Oct. 7, 1901) made a series of experiments, with the following findings: (1) The skin cannot be made absolutely sterile, as the deeper strata remain septic, despite all aseptic and antiseptic measures. (2) A pack of soft soap or a one-per-cent. solution of formalin applied the day before operation renders the superficial skin sterile in 30 per cent. of all cases. Bichloride produces sterility but once in ten times. (3) Sutures become infected in their passage through the deeper layers of the cutaneous tissue, as shown by cultures from sutures passed through skin which is superficially sterile. (4) The path of a suture may be sterilized by passing the needle, which carries the thread, through a flame immediately before the stitch is taken. A fine needle should be used, and introduced rapidly; a coarse needle, slowly introduced, produces injury to the tissues. A fresh needle and suture for each stitch are essential to the success of this method. (5) Cultures from wet dressings show presence of bacteria which live only in moist surroundings; a dry dressing is to be preferred.

A Simple Fracture Support.—The difficulty with which pressure-sores are prevented in the ordinary Buck's extension apparatus for fractures of the lower extremities is overcome by the following simple device described by R. KLAPP (*Deut. Zeitsch. f. Chir.,* Sept., 1901) as follows: (1) Two uprights, one on either side of the bed placed opposite the knee; (2) a cross piece, firmly fastened to the top of these, bearing over the injured limb a pulley; (3) the leg is now surrounded by a long, loose canvas sling which reaches from the heel to the crotch; (4) through the loose portion of this is passed a pole long enough to project about four inches beyond either extremity of the canvas sling; (5) a strong rope is passed over one end of this pole, through the pulley, to the other where it is attached so that it lifts the limb from the bed; (6) the usual Buck's extension having been applied and the right adjustment of the above apparatus having been arrived at, the limb rests easy with the pressure upon it uniform from end to end and all possibility of bed-sore is avoided. In applying the Buck's extension he finds the following little plan very convenient for making the pull of the plaster even all over the leg: The side extensions of the plaster are slit into three pieces from their ends to a point opposite the sole of the foot; the middle of the three strips is gummed evenly upon the skin all the way up; the front strip is then carried over the shin and twice spirally around the leg, terminating just above the knee, and the back strip is similarly carried twice around the leg terminating as the other. Since the middle strips are first applied these spirals overlie them and hold them firmly in place and make an even pull on all the surface of the lower extremities themselves. All these features, he says, add greatly to the comfort of the patient.

Flagella Staining with Night Blue.—The methods commonly employed for flagella staining do not give altogether satisfactory results. This is principally due to the fact that in such two solutions are employed—a mordant and a stain. In case of failure to obtain the desired result it is thus difficult to locate the cause of error. LECTHWORTH SMITH (*Jour. Med. Research,* Nov., 1901) reports satisfactory results from the use of Newman's method. As this method has not come into general use and is not to be found in the usual text-books, a description of it is of interest. The cover-glass preparation is prepared in the usual way with the exception that no fixation by heat is necessary. The flagella stain is then filtered on and allowed to remain for five or ten minutes. This stain is prepared as follows: Tannic acid, 1 gm., and potassium alum, 1 gm., are dissolved in 40 c.c. of distilled water and placed in the incubator over night. To this is then added 5 gm. of night blue dissolved in 20 c.c. of 95 per cent. or absolute alcohol. The whole mixture is then filtered. The stain should always be freshly prepared. After staining the flagella the preparation is washed in water and the bodies of the organisms stained with aqueous gentian violet solution for two minutes. The preparation is then washed in water, dried with filter paper and mounted in balsam.

Uterine Cough.—Coughs of reflex origin are always difficult to treat and none more so than those which proceed from the uterus. L. ARCHAMBAULT (*Gaz. de Gynéc.,* Oct. 15, 1901) states that the following indications must be fulfilled: (1) To diminish the excitability of the reflex center in the bulb, chiefly with opium, morphine, bromides and other sedative drugs; (2) to quiet the point of departure of the reflex, *i.e.,* the uterus itself, which must be treated for any unnatural condition existing there, such as displacements, ulcers and the like; (3) to influence

the centrifugal paths, for example, by active counterirritation over the small of the back and sometimes by stimulation of the phrenic nerve; (4) to exercise an inhibitory influence on the cerebral nerve centers. This means that the physician should exercise suggestion with his patient and impose upon her the necessity of greater self-control. The special means of carrying out these various indications are sufficiently common in the knowledge of everybody to make mention unnecessary.

Nature of Fat in Chylous Urine.—The origin of the fat in chylous urine has been variously ascribed to the (1) degeneration of the epithelium of the urinary tract, (2) secretion of fat by renal epithelium, (3) direct passage of fat from blood to urine, and (4) direct passage of fat from chyle to urine. The results of experimental research have excluded the first three of the sources and at present it is believed that the fat in the urine is derived directly from the chyle. The nature of this fat is of interest from several standpoints and has recently been inquired into by A. E. AUSTIN (*Jour. Med. Research*, Nov., 1901). By a complicated method of analysis which involves repeated extraction with alcohol and ether, he shows that the fatty acids are present only in small traces and that the greater portion of the fatty constituents is made up of glycerides or neutral fats. This is to be expected in accordance with the accepted theory of the origin of the fat. Of the fatty acids the largest proportion is oleic acid, the remainder being made up of stearic and palmitic acid. The oleic acid thus found is peculiar in that it remains solid at 29° C., while normally it fluidifies at 14° C. Large amounts of cholesterin are also present.

Diagnosis of Glanders.—Strauss was the first to point out the fact that if virulent glanders bacilli are introduced into the peritoneal cavity of a male guinea-pig peculiar suppurative lesions of the scrotum generally result in a few days. This method of glanders diagnosis has been extensively utilized as a rule with favorable results. LANGDON FROTHINGHAM (*Jour. Med. Research.*, Nov., 1901) reports the examination of 312 horses and two men by this method. Of these 123 horses and both the men gave positive results. Of the 189 horses which gave negative results 35 were afterward killed as glandered. In conducting this test the material for inoculation is obtained from the mucous or cutaneous lesions by means of a sterile swab similar to that generally used in diphtheria work. The cotton is then removed and violently shaken in a small amount of distilled water which is then inoculated intraperitoneally into at least two guinea-pigs, due antiseptic precautions being employed. In considering the results obtained it should be remembered that when glanders lesions are healing the bacilli in them are probably less numerous and perhaps less virulent than in the early stages of the disease; furthermore that the guinea-pig is not highly susceptible to glanders. It is thus seen that while a positive result means everything, a negative result is of little value unless several trials have been made. At every trial three or four guinea-pigs should be used, each pig receiving an inoculation of one-half to one cubic centimeter of the suspension of the organisms.

Tubo-Ovarian Cysts.—Among the abnormalities to which the genital tract in woman may be subject is one which exists normally in some animals, *viz.*, the tube is directly continuous with the ovary. G. PREISER (*Arch. f Gyn.*, B. 64, H. 3) presents the following conclusions on this subject: (1) A congenital "ovarian tube" has not yet been definitely proven in man. (2) The majority of tubo-ovarian cysts have the following origin: A sactosalpinx and ovarian cyst adhere together and the separating membrane later undergoes an atrophy by pressure. In cases where this relation exists at the fimbriated extremity of the tube the deceptive condition arises of an artificial ovarian tube. (3) The origin of a tubo-ovarian cyst in the manner of a hematocele is conceivable, but the frequency of the condition on both sides and the absence of blood elements in the contents of the cysts make it unlikely. (4) The presence of genuine tubo-ovarian cysts in the cavities of which fimbriæ either float free or are grown to the walls is explained probably by the theory that after the original growth of tube to ovary an exudate about them takes place. This exudate encloses them and finally becomes the outer wall of the cysts making the tube in part its contents.

Carcinoma, Pregnancy and the Climacteric.—The influence which pregnancy and the climacteric have upon the permanent results of radical operations for cancer of the uterus has lately been studied by K. HENSE (*Zeitschr. f. Geburtsh. u. Gynäk.* B. 46, H. 1). His conclusions are, briefly, (1) that the climacteric in itself has the greatest influence in determining a better prognosis for carcinoma of the uterus, especially that of the body; (2) that radical operations for carcinoma during actual pregnancy, at the time of childbirth and during the puerperium give, in point of fact, the worst prognosis of all; whereas those performed after the menstrual flow has stopped give the best prognosis.

Tuberculous Seminal Vesiculitis.—The invasion of the genital tract in the male by the bacilli of tuberculosis is now a diagnosis frequently made. In treating this condition surgically H. YOUNG (*Ann. of Surg.*, Nov., 1901) elects the suprapubic route. He makes an incision in the middle line from the symphysis to the navel. Just above the navel, it is joined by a transverse incision through the linea semilunaris, both are deepened until the peritoneum is reached, without opening the peritoneal cavity, the bladder is freed all around of its serous coat until at the base the disease is reached. The bladder is then opened, catheters are passed into each ureter so that they shall not be damaged

during the rest of the operation. After this has been done, the prostate gland and the seminal vesicles with the vasa deferentia are removed. The recovery from this operation is usually good and the transverse incision through the recti muscles seems to do but little damage.

Rachicocainisation.—The French surgeons are still much interested in the use of cocaine within the spinal canal as a means of anesthesia for operations below the diaphragm. KALLIONZIS (*Rev. de Chir.*, October, 1901), after reviewing the records of this method in literature, points out that surgeons are to-day in much the same position regarding it as they were when chloroform was first introduced. Since, however, the methods of giving chloroform have so much improved, it is to be expected that many of the objections against the use of cocaine in this manner will shortly be surmounted. He alludes to the methods suggested about a year ago by Tuffier in Paris. Under this method with a small dose complete anesthesia is obtained, with very few or no bad after-effects.

Parallel and Simultaneous Auscultation.—The difficulties of making comparison between the conditions of the lungs on each side with the ordinary stethoscope have been surmounted by BOURGET (*La Sem. Méd.*, November 6, 1901) by the following method: An ordinary stethoscope bell with a long shank is fixed to a piece of rubber tubing. At the other end of this tubing is a self-retaining ear-piece. Such is the single instrument. There must be two, one for each ear. The examiner now stands before the patient, places the ear-pieces in his ears and, with a bell in each hand, starts at the upper part of the chest and works downward on each side in orderly fashion, placing the two bells at the same points on each side. The author claims that this device is accurate, labor-saving and time-saving.

Gall-Bladder Wounds.—The familiar difficulty with which wounds of the gall-bladder sometimes heal, inspired Enderlen and Justi (*Deut. Zeitsch. f. Chir.*, Oct., 1901) to undertake experiments on dogs directed toward filling defects in the gall-bladder by means of omentum. Their results are interesting and as follows: (1) Wounds of the gall-bladder heal with complete restoration of the mucous membrane. (2) Copious suppuration and hindered outflow of necrotic masses check the healing. (3) The new epithelium shows at first low forms which change on developing into the high cylindrical epithelium. (4) The regeneration of the muscular coat is somewhat incomplete. (5) A tendency of the epithelium to grow along the holes made by silk threads is present in only a few cases. (6) The transplanted omentum is absolutely adapted to replace defects in the gall-bladder. (7) In the omentum there is first a development of the connective tissue followed by much shrinking. (8) On the transplanted omentum there is well spread out a covering of epithelium beneath which the new mucous membrane soon appears. (9) The original defect gradually grows smaller on account of the shrinking in the omentum and the contraction of the muscular coat. Practical obstacles against the transplanting of the omentum rarely occur. (10) In the dog the gall-bladder may be opened and spread out upon the liver. Soon, however, with the aid of the liver-substance a cavity is formed which tends to carry out the functions of the gall-bladder.

Ozena.—The present status of the pathology and therapeutics of this disease is summarized by E. BARTH (*Fortschritte d. Med.*, Nov. 22, 1901). The true etiology is still undecided for it remains a matter of dispute whether the condition is merely a symptom or an idiopathic disease *per se*. Syphilis, purulent inflammation of the nose or its accessory sinuses, neuropathic degenerations, atrophic processes in the mucosa, specific bacteria or other parasites, rudiamentary development of the turbinates, have all been suggested as causative factors. In the latter case an abnormal widening of the nasal canal is produced, followed by certain changes in the lining mucosa, so that the secretions probably become largely deprived of their bactericidal functions. The trophic nerve disturbance is undoubtedly a leading factor. As far as therapeutic measures are concerned nothing has been found as yet to give permanent relief. Curettage of the nasal mucosa or removal of the already atrophied turbinate is not to be recommended, for these procedures undoubtedly aggravate the trouble. The foul odor and the crusts can be quite largely obviated by irrigations and tamponade. The least dangerous method of irrigation is by the pharyngeal route, using weak solutions of salt, sodium bicarbonate or potassium permanganate. The tamponate is best made with tightly-fitting plugs of non-absorbent cotton, without medication, applied to each nostril alternately and left in place for twenty-four hours. It is very important to continue the treatment daily and without intermission. A new drug from which good results have been reported, on rather incomplete trials, is a sodium sulphate salt of phenol.

Xanthoma of Eyelids.—These yellowish patches on the eyelids resembling chamois leather are slightly elevated, soft, without heat or redness, are not hereditary and most frequently develop after puberty. F. J. LEVISEUR (*Med. Rec.*, Dec. 7, 1900), says that the region of the left upper eyelid is most frequently affected and the growth very seldom becomes malignant. It has been proven not to be a neoplasm, but the product of degeneration of embryonically misplaced muscle fibers. Internal medication is useless in treatment, but excision is recommended by most authors. The cautery and caustics cause too wide destruction of tissues. Electrolysis attacks the degenerated tissues only, its action being local and under control, and the pain which is occasioned is very slight. The positive pole is held in the hand of the patient, the negative pole being connected with a needle which is inserted hori-

zontally into the xanthoma. The hydrates of calcium potassium and ammonium which are found on the negative pole also serve to destroy the tissues. Healing occurs rapidly.

Hemorrhagic Diathesis in Nose and Throat Work.—The difficuly in controlling hemorrhage from the nose and throat is easily recognized and hence it is always important to avoid operations, if possible, upon patients who are prone to bleed easily. E. H. GRIFFIN (*Med. Rec.*, Dec. 7, 1901), shows what a tendency there is among patients to deny a bleeder's history when an operation is desired by them, and yet, if severe hemorrhage occurs, one may frequently obtain subsequently a good hemophilic history. He reports two cases in which every means were used to control hemorrhages induced by operations upon the turbinated bones and tonsils, which might have been avoided if the true history had been given. Plugging is usually necessary in severe cases, but it is better to employ anterior plugs only if possible. He strongly recommends morphine to control the patient and quiet the excited efforts which interfere with clotting.

THERAPEUTIC HINTS.

Erysipelas.—When the fever is alarmingly high it must be reduced by cold sponging, cold baths, ice-cap, guaiacol applied externally, etc. For pain, sleeplessness and active delirium hyoscin hydrobromide, gram 0.0006 (gr. $^1/_{100}$), is indicated, or sodium bromide, gram 0.3 (gr. v), every two hours, or gram 1.3-2.0 (gr. xx-xxx) at night, or morphine, gram 0.008 (gr. $^1/_8$) and chloral, gram 0.65 (gr. x), every half hour for three doses, or atropine and morphine, or potassium bromide and tincture of cannabis, gram 0.65 (ℳx). Iron and quinine and alcohol and strychnine should be given with a free hand. The air can be excluded from the part, an important procedure, by carbolized vaseline. As the streptococcus is found in the more superficial channels of the corium, scarification with the application of mercuric chloride solution, 1:4000, is a rational antiseptic treatment.—J. M. ANDERS in "Practice of Medicine."

Influenza.—An efficient diaphoretic, given early, may abort the attack; otherwise calomel should be given for a day in small doses. The neuralgia and myalgia may be relieved by quinine, Dover's powder and ergot. When the temperature is above 102° F. (38.8° C.) order cool sponge baths every two or three hours, or give quinine and salol or phenacetin. Sleeplessness may demand trional, chloralamid, opium, etc. The coryza is relieved by inunctions of animal fats over the forehead and nose, or by steam inhalations. The laryngobronchial irritation may be controlled by

℞ Codeinæ sulph..... 0.25 (gr. iv)
Ammon. chloridi..... 20.0 (℥v)
Syr. pruni virg..... 60.0 (℥ij)
Spt. junip. comp. ad...120.0 (℥iv)

M. Sig: One teaspoonful every two or three hours.

Oil of eucalyptus, gram 0.2-0.35 (ℳiii-v), in capsules every four hours, is useful when the bronchial secretion is very free. Chest pains may be relieved by turpentine stupes and sinapisms. In the severe forms, stimulation must be carried on with heroic doses, strychnine and the aromatic spirit of ammonia being the most generally useful. Convalescence demands rigid supervision, the greatest injury resulting from going out too early. Gentian, iron and quinine form a good tonic till health is restored.—J. M. ANDERS in "Practice of Medicine."

Carbolic Acid for Tetanus.—The cure of tetanus in a man who presented himself with a filthy dressing over a chronic ulcer on each leg is reported by DAVID SMART (*Liverpool Medico-Chirur. Jour.*, Sept., 1901). Ten c.c. (℥iiss) of tetanus antitoxin were injected, and repeated in twenty-one hours without effect, and the author thinks the dose may have been too small. Then 1.3 c.c. (twenty minims) of 1 to 50 carbolic acid were given hypodermically every three hours. Twenty-eight injections in all were administered, and after the first day steady improvement took place and continued till the patient was cured. The hypodermic solutions produced neither local irritation nor carboluria, although at the same time the ulcers were being dressed with 1 to 40 carbolic. Chloral and bromide were given throughout the disease, but the author thinks that these were of only secondary importance.

Uremic Convulsions.—In a case of acute nephritis, T. R. GLYNN (*Liverpool Medico-Chirur. Jour.*, Sept., 1901) administered purgatives and diaphoretics, including the hypodermic injection of pilocarpine and the restriction of food to diluted milk, yet in four days uremic symptoms developed, with repeated fits, coma, stertor, cyanosis and contracted pupils. Two pints of blood were then drawn, and a pint of saline solution injected into the connective tissue in the axilla, and shortly after half a pint was injected into the rectum. The convulsions ceased, consciousness returned, the nephritic symptoms ceased, and for the following ten days he passed 2,100 c.c. (70 oz.) of urine a day, whereas before the saline treatment 600 c.c. (20 oz.) had been the maximum.

Haab's Magnet in Eye-Work.—The old Snell magnet is too weak to be of much use, writes RICHARD WILLIAMS (*Liverpool Medico-Chirur. Jour.*, Sept., 1901), but by its great strength, Haab's magnet may be a source of danger. He reports two cases of the extraction of pieces of steel from the inner chamber of the eye by this magnet, the power of the magnet being so great that it caused bulging of the tissues when they were too dense to be perforated by the piece of steel. In one case the foreign body was drawn right through the iris, with considerable bleeding into the anterior chamber, and, on account of bulging of the cornea, there was dangerous lateral collapse of the globe.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

SATURDAY, DECEMBER 14, 1901.

NEW YORK'S HEALTH COMMISSIONER.

AT a dinner given by the alumni of Columbia University to Mayor-elect Seth Low, at Sherry's last Tuesday night, Mr. Low spoke of the duty he owed as a son of Columbia to the City of New York. We all know how nobly, honorably and well he will discharge that duty.

The choice of the Commissioner of the Department of Health is no easy matter. We feel that he should be a physician. There are other students of hygienic science than medical men, but the work of a health commissioner is wider than that of a mere hygienist or sanitary engineer. Only the worker among the sick of a large population has a realizing sense of the problems involved in the combat with disease, both physical and social.

A bacteriologist, a chemist, a pathologist, a sanitary engineer, no matter how eminent he may be in one line of research, is fitted only in most exceptional instances to cope with the complex conditions present in the City of New York.

From the other point of view it will be a difficult task to find a physician who is at the same time a doctor, a hygienist, a sanitary engineer and an executive officer of high ability. Indeed, the combination is a rare one. We feel assured that our Mayor-elect will find such a man.

FRESH AIR IN RESPIRATORY AFFECTIONS.

ONE of the most striking utterances at the semi-annual meeting of the New York State Medical Society was that of Dr. Hunter of Toronto, who declared that if he were to be taken down with pneumonia in New York City he would prefer a cot under the trees in one of the parks than a bed in the best private room in any of New York's magnificent hospitals. He was not slurring the hospitals, but expressing forcibly the conviction brought home to him by his favorable experience with the treatment of patients suffering from pulmonary affections in tents on the grounds of the Western Hospital of Toronto. Dr. J. C. Wilson of Philadelphia confirmed this opinion by stating that to his own knowledge the mortality from pneumonia in lumber camps, where it is not an unusual disease because of the exposure incident to the life, was much less than under the apparently more favorable conditions of city life.

These expressions of opinion represent by no means new discoveries, but they recall old truths that are constantly lost sight of or at least partially neglected in medical practice.

There is still extant among physicians, as well as their patients, an unreasonable dread of cold and of the dangers of damp air. Draughts are thought to be particularly dangerous for patients with febrile temperature. Recent clinical experiences serve to show that while the body temperature is higher than normal there is nothing that gives greater comfort to the patient than cold fresh air. The superstitious prejudice that fifty years ago kept cold drinks of all kinds from fever patients and hugged the delusion that it was doing most good when making the patient most uncomfortable has left behind it the almost as unreasonable medical fetish that cold air will surely do harm.

In the sanatoriums where in recent years tuberculosis has been treated with so much success, the value of fresh air is appreciated at its true worth. Patients who go to sanatoriums in the Engadine, in the Tyrol, and even here in the Adirondacks, are taught to fear nothing less than fresh air, no matter how cold it may be. It is not an unusual thing to have returned patients cured of their serious pulmonary tuberculous condition report that their windows were open

on the coldest nights, so that water kept in the room was frozen in the morning, while at times the patient awoke to find that an inch or more of snow had silently drifted over the bed-clothing. Colds in the healthy and exacerbations of the catarrhal conditions in the phthisical are not due to low temperature. Nansen spent a winter in the frozen North without suffering from a cold and had to take to his bed with a grippy cough before he had been a week in the temperate zone. The development of acute symptoms in the consumptive is much more likely to be due to overexertion than to exposure to cold.

While ordinary cold air is very much dreaded, night air comes in for particular condemnation. It is not easy to understand how night air obtained its bad reputation. In tropical countries, or rather in malarial regions and the countries in which medical traditions developed were practically all malarial, night air was set down as especially dangerous because it was noted that exposure at and after nightfall was liable to be followed by an attack of the disease. Malaria, as its etymology shows, was thought to be due to unwholesome air, hence the rise of the prejudice against night air. We know now that malaria is due to the mosquito, which does not bite during the day and whose favorite marauding time is just after nightfall. The prejudice against night air and the mythical dangers associated with it will not die easy however.

As a matter of fact, night air is a little purer than the air of the daytime. There is less disturbance of dust particles, because of the absence of commercial activity, and there is consequently less irritating material in the air and fewer bacteria-carrying particles of many kinds. The lowering of the temperature during the night brings the humidity to the saturation point with consequent deposition of moisture from the air and also of undesirable floating germ material. It is time, then, to do away with all the unfounded ideas as to the possible harmfulness of air under any circumstances, night or day. Patients are sometimes kept in rooms in which healthy individuals would become ill if confined continuously for any length of time. Physical conditions that would do harm to the well can scarcely be hoped to benefit those who are seriously ill.

For children and for patients suffering from respiratory disturbance or from lack of cardiac compensation that interferes with the processes of internal respiration, an abundance of fresh air is the primary indication, the most important adjuvant for the restoration of health. Unfortunately, it is prone to be in just these patients that the prejudice against fresh air exerts its harmfulness. In the case of delicate patients the temperature may have to be maintained, but this should never be an excuse for insufficient ventilation. Patients will have many less complaints to make and their general comfort will be greatly enhanced by a never failing supply of fresh air, not loaded with antiseptics, but with the vital properties that sunshine imparts to it.

ANTIVIVISECTIONISTS AS ANTIVACCINATIONISTS.

THE antivivisection agitations are rapidly confirming the diagnosis which even the unpsychiatrical public long since made of their mental status, for those who live in Boston are now putting all their energy and probably most of their funds in a crusade against vaccination. At any time this is bad enough, but at present when smallpox is more prevalent than it has been for many years, and not a few cases every week in Boston, it is particularly unpleasant. At present no statute covers offenses of this nature in Massachusetts and the only ones who will suffer for the agitation are the few misguided ones who will needlessly take smallpox thereby, together with their families and fellow-citizens. The unfortunate ignorant will perhaps occasionally fall unwilling victims to this one of the worst of modern mental "squints." This influence would not be felt did not they fill their circulars with misstatements well capable of deceiving any not aware of the irresponsible source of the whole disgraceful agitation.

But it is not the most ill of winds after all, although the good it blows lies in a somewhat different direction. It may none the less compensate the public sooner or later for this immediate unmistakable injury. This will probably serve as the death-knell of their antivivisection annoyance in Massachusetts, if not in a much larger sphere. That this is so was recently suggested by an editorial in a prominent Boston paper, saying "The antivivisectionists' league has put an end to what little influence it may ever have possessed previously by this vicious attack upon vaccination." To the informed, the antivivisection hearings at the State House the last two springs have been weeks of more or less intolerant sympathy with delusion, but to the pub-

lic at large (so far as they ever heard of it) they have been agitations with more influence (however slight) than interest, appealing sometimes to the hyperesthetic emotions of women (and occasionally of a man) who quite refused to lend attentive intellect to the discussions. But most of these people must believe in vaccination. At any rate the common diagnosis of the agitators' case certainly is confirmed.

ECHOES AND NEWS.

NEW YORK.

Cornell Medical College Entering Class.—In this, the first entering class of Cornell Medical College for the full four-year course, 181 students have registered.

Albany Hospital Enriched.—Under a decision of the Appellate Division the Albany Hospital will receive $50,000 by the will of Ellen M. Campbell, sister of the late Allan Campbell, formerly Comptroller of New York City. The cause making the bequest to the hospital for the maintenance of a separate ward for cripples was opposed by the Home for Aged Men, which carried an appeal to the Appellate Division from the decree of the Surrogate. The Home for Aged Men is given $5,000 under the will. There are bequests to other benevolent societies. The original will provided for the erection of a monument to Sir Walter Scott in Albany, but by codicil this was revoked.

Smallpox Cases Unreported.—The Health Department officials in Brooklyn yesterday began an investigation to fix the responsibility for the Department's being kept in ignorance of the existence of several cases of smallpox in an apartment house at 1,634 Eighth Avenue. It is alleged that two physicians, who attended the patients, failed to report the cases to the Department. The existence of smallpox in the house became known to the department on Friday, when one patient, who lived in the building, died of the disease. Dr. John E. Walsh, diagnostician of the department, visited the house and was surprised to find that four children were also ill with smallpox. All of the children were removed to North Brother Island.

German Hospital Annex Dedicated.—August Zinsser, Chairman of the Building Committee of the German Hospital and Dispensary, yesterday formally turned over to Carl Schurz, representing the Trustees, the new annex, which has been in course of construction for more than a year past, and which is now ready to receive patients. The new building, which is a five-story brick structure, is 45 feet wide fronting on Lexington Avenue, and 80 feet fronting on Seventy-seventh Street. It was designed principally to accommodate private patients, but there is room in it also to relieve the free wards of about sixty persons, so that the capacity of the hospital has been increased to the number of about 125. The addition is fireproof and cost $180,000.

New York University and Bellevue Medical College.—The report of the Medical Faculty shows that over twenty-five hundred examinations of material were made in the past year in the clinical laboratory of pathology, seven hundred of which were for the Bellevue Hospital, and the remainder for the classes in the university dispensary. The dispensary received fifty thousand visits from patients, an average of one hundred and seventy daily. Twelve researches were published from the physiological laboratory, and an equal number from those of pathology, chemistry, and bacteriology. Eighty per cent. of last year's class have received hospital appointments. The dispensary has received a gift of $2,000 for the purchase of material. The Scientific School catalogue shows an increase of 65 students in the school and 46 in the freshman class. In the entrance examination of the school, Roman or Greek history may be substituted for United States history, and in algebra quadratics will be required. There are three additions to the list of instructors and several new courses. The Medical School catalogue shows 147 students, a gain of 14, and a gain of 12 in the entering class. There are five changes in the list of instructors.

Scarlet Fever in Brooklyn Hospital.—The Brooklyn Health authorities and the Coroner's Office of that borough are about to investigate the case of a boy who had been treated at the Long Island College Hospital for a fractured skull and was removed after being there for two weeks to the Kingston Avenue Hospital, suffering from scarlet fever. He died at the latter institution on Friday night. This is the second case of scarlet fever taken from the same institution that has resulted fatally within a month, and it is declared that in each instance the patient was infected at the Long Island College Hospital. Dr. Robert E. Shaw, Superintendent of the Long Island College Hospital, said last night that it was impossible to prevent contagion in hospitals where visitors are permitted to come into close contact with the patients. He declared that in each case, immediately after discovering the presence of the disease, every precaution had been taken to prevent a spread of it.

Appointment of Dr. Pritchard.—At the November meeting of the Trustees of the S. R. Smith Infirmary, Staten Island, Dr. Wm. Broaddus Pritchard was appointed consulting neurologist to the institution.

Adjutant-General of the National Guard.—The appointment of Dr. Nelson H. Henry as Adjutant-General of the National Guard of this State has the approval of its leading officers. Although at first sight the selection of a surgeon for this high office would seem an anomaly, it is in accordance with the new spirit in Federal military circles, which makes for the interchangeability of line and staff duties. There can be no doubt that Dr. Henry has the ability and experience necessary for the proper conduct of

his office, and it is understood that he was unwilling to take the position until he had made sure that his selection would be acceptable to those on whose shoulder rests the responsibility for the welfare of the Guard. Dr. Henry has had more than fourteen years' service in the National Guard, besides having held a commission in the United States Volunteers. He has also served three terms in the State Legislature, where his record was of the best. Altogether, the appointment is one which is as full of promise for the National Guard as it is creditable to Governor Odell.

PHILADELPHIA.

University of Pennsylvania Accessions.—The Wistar Institute of the university is now in possession of a "Bone Library," which is said to be the only one of its kind in existence. The bones which make up this peculiar library include the skeletons of almost every animal known to science. Dr. Jayne, who is at the head of the Wistar Institute, has adopted an entirely new method of classifying and arranging these bones. Instead of mounting the complete skeleton, as is commonly done, the skeleton is disarticulated, and the bones are catalogued and placed in separate trays, following the order of cataloguing the books in the University Library. By this means it is made possible to study every bone in its proper class. The collection is so complete that the evolution of any particular animal can be studied through many generations. In the same way it is possible to trace out the relationship to some allied animal.

Tetanus in Camden.—The ninth death from tetanus in Camden occurred December 7th.

Salary for School Medical Inspectors Urged.—The Committee on Hygiene of the Board of Education will urge Councils to make an appropriation for a paid medical service. This action is necessary because of the inability to secure a full corps of volunteer inspectors, a number of schools now being without inspection which is especially needed at the present time.

Free Vaccination at Home to Check Smallpox.—The Department of Public Safety has organized a corps of forty physicians to make a tour of the city and offer free vaccination to the inhabitants of every house. Circulars setting forth the benefit and necessity of vaccination have been printed and placed in every house by policemen. The physicians are making a systematic canvass of the city under the supervision of one of the assistant medical inspectors of the Bureau of Health. They receive twenty cents from the city for each person vaccinated. While vaccination is offered free of charge, it is not made compulsory, one of the officials saying, "We do not consider that the present status of the disease in this city comes under the head of an epidemic and do not recognize it as such. Should the time come when we must regard it as an epidemic, then we will make vaccination compulsory, being so empowered by act of Assembly." All schoolhouses are being disinfected with formaldehyde gas on Friday and Saturday of each week. Statistics for the week ending December 7th show a decrease of 41 cases and 6 deaths from the previous week. The majority of the hospitals in this city are excluding visitors from the wards in order to guard against the introduction of smallpox. The citizens of the Twenty-eighth Ward still insist that the presence of the Municipal Hospital is the cause of smallpox in that section and clamor for its removal.

Hospital for Contagious Diseases at Atlantic City.—It is understood that the authorities at Atlantic City are contemplating the erection of a commodious hospital for contagious diseases. A tract of ground covering 26 acres is under consideration as the site of the building.

The Effects of Cerebral Compression on Intracranial Blood-Pressure.—This was the subject of the Mütter Lecture of the College of Physicians for the year 1901, which was delivered in the hall of the College Tuesday evening, December 3d, by Dr. Harvey Cushing of Baltimore. The lecture detailed the result of experimental and clinical observations regarding the effects of compression, with especial reference to the question of capillary stasis or capillary anemia as the result. Two groups of causal factors were considered, local compression caused by a tumor, abscess, foreign body, etc., and general compression, as in the increase of fluids in the brain. To observe the effects of compression a glass window was inserted in the skull of the animal employed a point over the longitudinal sinus being selected.

Local Compression.—This was produced by means of mercury in a cannula and bag. When a slight dislocation of the brain mass was produced the color differences were not marked. Later venous stasis appeared and, finally, capillary pressure lessened, the capillaries near the compressing body and then those more distant lost their color, and anemia of the hemisphere with venous stasis ensued. There are but few symptoms of cerebral compression when the circulation of the hemispheres is compromised by local pressure if the medulla is working properly. A foreign body from one-eighth to one-sixth the size of the brain can for that reason be harbored without giving rise to pressure symptoms. Upon the locality of the foreign body depend the symptoms produced.

General Compression.—This was secured by the injection of salt solution into the cerebrospinal canal. The resulting venous stasis first showed itself about the optic nerve and was thus detected by examination of the eye grounds. By means of other instruments the blood-pressure of the animal was then determined and a series of comparisons between this and the compressing force made. It has been stated that when general compression of the brain, affecting hemispheres and medulla, is raised to the point where the tension equals blood-pressure, the patient must die. This statement was proven to be er-

roneous by the fact that when this condition was reached the blood-pressure was by some means elevated sufficiently to still supply the brain. This elevation occurred repeatedly to counteract increasing tension until in some instances it was two or three times the height of normal blood-pressure.

The Cause of Blood-Pressure Rise Under Increased Intracranial Tension.—Experiments were then conducted to determine the cause of the increase of blood-pressure. It was found that when the pneumogastric nerves were divided tension and blood-pressure followed each other more easily. If the cord was divided, thus cutting off vasomotor control, there was no blood-pressure rise under the stimulus of increased tension. If both the cord and the pneumogastrics were divided no alteration in the pulse was caused by increased tension. The changes in blood-pressure were thus determined to be due to vasomotor control of the splanchnic center. When the medulla was cocainized no effect on blood-pressure was produced by variation in the tension. If intracranial tension was *suddenly* raised to the level of blood-pressure the vagus was stimulated and the heart completely checked. If tension was increased slowly there was no period of entire inhibition. The rhythmic changes in blood-pressure which sometimes occur are by the above facts easily explained. Under increased tension anemia ensues and then blood-pressure rises, going to a height more than necessary to counteract the tension. It then falls because of the tension and again rises. This produces waves in the blood-pressure, good circulation and anemia alternately.

Conclusions Reached by the Experiments Detailed.—In cases of death from cerebral compression respiratory failure precedes heart failure, instances being cited where the heart beat for hours after respiration ceased. But before this respiratory failure takes place there is a collapse of the vasomotor mechanism. Sudden removal of intracranial tension is dangerous in some cases. Multiple ruptures of vessels may take place and cause immediate death. Venous stasis following modification of the tension is early evidenced in the eye grounds. Local pathological processes may cause the cessation of circulation in a large part of the forebrain without causing untoward results if the medulla is not involved. Persistent rise of blood-pressure is a late and dangerous symptom in cases of compression, as it is due to approaching anemia of the medulla.

Albuminoid Expectoration.—At the December meeting of the College of Physicians Dr. David Riesman discussed this subject and reported a case. The patient was a woman, forty-eight years of age, who had a chronic pleurisy of one year's duration. After tapping the chest, with removal of three pints of fluid, the woman expectorated during six hours about one gill of a frothy, yellowish, slightly blood-tinged fluid. A second tapping was done some time later, but there was no true albuminoid expectoration. The fluid expectorated in these cases tallies closely with the fluid drawn from the chest. In these cases the expectoration begins from a few minutes to half an hour, or rarely two hours, after the tapping. In some instances a pint or a quart is expectorated. Acute cases are most liable to this complication. The following four explanations of its occurrence which have been advanced were analyzed: (1) Perforation of the pleura by the tapping instrument; (2) spontaneous perforation; (3) absorption of fluid by the lungs; (4) pulmonary edema. The latter is believed to be the true explanation and the following conclusions were drawn: (*a*) Albuminoid expectoration is rare; it is a serious and sometimes fatal accident; (*b*) it is due to the too rapid withdrawal of fluid or the removal of too large amount; (*c*) it is caused by an intense congestion of the lungs.

Successful Serum Treatment for Tetanus Reported.—Newspaper reports from Pittsburg claim for a worker in the Pathological Department of Mercy Hospital the discovery of a successful serum treatment for tetanus. Animals have been experimented upon for a year or more and recently three persons were treated with the serum, recovery following in each case. No details of the method are given.

CHICAGO.

Changes Contemplated in Medical Staff at Dunning.—Members of the County Civil Service Commission are preparing to meet probable changes to be made in the resident medical staff of the Dunning institutions as a result of the deliberations of the Advisory Commission appointed by President Hanberg of the County Board, with a view to improving conditions there. While no definite action has been taken, the staff may be increased and an effort will be made to raise the salaries of those physicians who are required to give their entire time to the County. In view of these facts the Civil Service Commission has adjourned the physicians' examination until December 16th, in order that the test may be given greater publicity and that in the light of a possible reorganization of the staff a greater number of applicants may be able to take the examination. Members of the Commission are particularly anxious to secure a good eligible list by the first of the year, when a number of important appointments will have to be made. At the time President Hanberg appointed the Advisory Commission to look into the conditions at Dunning he particularly directed its attention to the need of an improvement in the organization and efficiency of the medical staff. Members of the County Board are in accord with his determination to improve this important service in the county institutions, and there is no doubt changes will be made immediately upon receiving the report of Dr. Frank Billings and his associates of the Advisory Commission.

Dr. Frances Dickinson Honored.—The students and faculty of the Harvey Medical College

have presented Dr. Dickinson with a life-size portrait of herself. She is the president of that College. Last year she was made president of the Illinois Educational League, which was incorporated to foster extension work done by the University of Illinois.

Typhoid Fever in West Pullman.—An investigation of a local outbreak of this disease in West Pullman showed that ten out of eighteen families affected had been receiving milk from one dealer. His place was visited and taken charge of by one of the milk inspectors pending radical improvement in the drainage and water supply of the premises.

Non-Liability of Charity Hospitals.—In a suit for $25,000 damages brought against the Presbyterian Hospital on account of injury alleged to have been the result of a mistake in medicine made by a nurse, Judge Chytraus instructed the jury to find for the defendant on the ground that a hospital chartered for the purpose of receiving and treating patients without charge is not liable for the carelessness or negligence of its servants, providing it has selected those servants with due care.

People's Hospital and Training School.—An institution bearing this name has been incorporated for the purpose of educating nurses. The incorporators are Drs. I. C. Gary, Gordon C. Burdick, George W. Webster.

Addition to Mercy Hospital.—This institution has purchased for $20,000 property on Prairie Avenue, and expects to extend the hospital to cover the 98 feet of frontage thus secured.

Chicago Surgical Society.—At a meeting, held December 2, 1901, Dr. Carl Beck detailed his experimental and clinical observations on surgery of the liver. Dr. Wm. M. Harsha reported a case of abscess of a sarcomatous kidney which simulated appendicitis. He likewise narrated an interesting case of tubal pregnancy of the fifth or sixth week, which was operated on, with recovery of the patient.

Filariasis.—Dr. Joseph L. Miller read a paper on this subject. He gave a detailed report on the urinary findings of two cases diagnosed as filariasis based on the presence of a nematode supposed to be embryo filariæ. Other decided evidence of filariasis was lacking. The worms were found only once in each of these cases, and on both occasions the patient brought the urine to the physician in a bottle. On account of the difference in size and structure, it was decided that the worms were not filariæ, but anguillula stercoralis, a parasite first reported associated with Cochin-China diarrhea. Failure to find previous reports of their presence in the urine and their detection in only one specimen of urine in each of these cases led to the suspicion that possibly they were not the anguillula stercoralis, but a very closely related non-parasitic form whose presence could be accounted for by the use of an unclean receptacle. The anguillula aceti, or vinegar eel, belongs to the same genus. Specimens were obtained and compared with the worms found in the urine and found to be identical in size and structure. Cultural experiments demonstrated that the vinegar eel could live and multiply in acid or alkaline urine. It was decided that the worms found in the urine of these two patients were the anguillula aceti or vinegar eel, their presence being accounted for by the use of a bottle that had previously contained vinegar.

Chicago Medical Society.—At a meeting, held December 4, 1901, Dr. Robert B. Preble detailed a case of aortic aneurism. The case was interesting because the man presented so many of the late manifestations of syphilis, and among them aortic insufficiency, aortic aneurism, and tabes. Dr. M. Friend showed and demonstrated a case of syphilis hereditaria tarda and exhibited numerous skiagraphs. Dr. Joseph B. De Lee read a paper on "Infant Incubation and Incubators." He presented a new incubator and described the system in use at the Chicago Lying-In Hospital. Dr. P. C. Clemensen read a paper on "Finsen's Phototherapy."

Public Health of Chicago.—The last report from the Department of Health says that, on the whole, Chicago has reason to be fairly well satisfied with its public health conditions during the month ending November 30, 1901. The average November mortalities of the previous ten years, 1891-1900, was at the annual rate of 14.16 per thousand of population. The 1,811 deaths from all causes recorded last month give an annual rate of 12.52, a decrease of 11½ per cent. The period of smallpox incubation has passed without any case having developed among Chicagoans from the four cases imported about a fortnight since from infected localities in Minnesota. Apprehension concerning the eighty "suspects" known to have reached the city soon after these four cases is also subsiding, since none of these has yet shown up with the disease. Conditions of the other contagious and infectious diseases were generally reassuring at the close of the week. Except an outbreak of a mild type of measles in Ravenswood and of a severe type of scarlet fever at Cheltenham there is no report of any unusual spread of this group of disease.

GENERAL.

Smalipox in New Jersey.—Twelve cases of smallpox and a fear that the disease will spread have caused consternation in the village of Sayreville. There was a great rush to be vaccinated last week, and the town Board of Health was forced to use the Town Hall to accommodate the people. Dr. J. H. Beekman, the Health Board physician, vaccinated 375 people up to noon to-day. There are two large factories in the neighboring village of South River. Many of the Sayreville people work there. Upon the recommendation of physicians, the management of the factories served notice upon the employees from Sayreville that they must not re-

turn to work until the epidemic is under complete control.

Dental Congress in Italy.—An Odontiatric Congress was recently held at Milan, when resolutions were passed asking for the establishment of chairs of odontiatry in all Italian universities having a faculty of medicine, and for the prohibition of dental practice except by holders of a diploma obtained after adequate course of education and examination.

Medico-Psychological Association of Great Britain and Ireland.—The stated autumn meeting of this Association was held November 21st. Sir Lauder Brunton delivered an address, in the course of which he said that hallucinations are perceptions having no objective cause; illusions are perceptions having an objective cause, but wrongly interpreted; visions he defined as hallucinations of the sense of sight; and apparitions as appearances or hallucinations affecting some one person or thing that the person seeing the vision has known.

Smallpox in London.—During the first three weeks of November there was a very marked increase of this disease both in the city and suburbs of London. Owing to the difficulty of making a positive diagnosis during the early stage of the disease—bacteriological examination being unavailing—special medical officers have been appointed to consider and pass upon all suspected cases.

Medicine in Madagascar.—A school of medicine for the training of native practitioners was established in Tananarive in 1897 and up to the present time has sent out fifteen graduates and now has 104 students. The curriculum is of five years duration and resembles that of the schools connected with the Faculties in France. Clinical instruction is given in a native hospital of 125 beds. These native-born practitioners will on graduation have the opportunity of competing for appointments in the Colonial Medical Service, in which the salaries run from $300 to $900 a year.

Chinese Doctors.—A leading Chinese newspaper has put forth a lament for the degeneracy of native physicians. Time was when the great men of China would take the prescription only of a man who represented the third generation, at least, of a family of physicians, and, hence, death rarely overtook the patient until old age had well paved the way. But how the present race of doctors have deterioriated! Many of them trade on the ignorance and superstition of their patients, forgetting that though they may deceive men they cannot hope to escape the eye of the gods. China has just awakened to the fact that in the enlightened West a man cannot practise the healing art until he has passed several stringent examinations and been declared so qualified by the Government. As in China all promotions, both in civil and official life, are made by examination, a petition has been presented to the Government to take the preparation for and practise of the art of medicine under its fostering care. The drugs and methods of European schools are looked upon with distrust and suspicion by the Chinese; but a few of the more intelligent and progressive among them are "getting into line," and a better and more rational state of affairs in the Chinese medical world is hoped for.

Nobel Prize.—It is announced that the Nobel prize for the encouragement of peace and arbitration, for 1901, amounting to 150,000 kroner (about $40,000), has been equally divided between Dr. Henri Dumant, the Swiss physician, who was recommended by the Swedish Rigsdag to the committee intrusted with bestowing the prize, and Frederick Passy, ex-member of the French Chamber of Deputies, member of the Academy of Moral Political Sciences and a leading apostle of peace, who received the next highest vote. The prize will be a special boon to Dr. Dumant, who is broken in health, in needy circumstances, and who is lying in a hospital in Switzerland. The Nobel medical, chemical, physical science, and literary prizes, amounting to 151,200 kroner each, and awarded, respectively, to Professor Behring, a German; Dr. Van t'Hoff, a Hollander; Professor Roentgen, and Armand Sully Prudhomme, a Frenchman of letters, were distributed December 10th by the Crown Prince in the Musical Academy at Stockholm.

Reappointment of Surgeon-General Van Reypen.—In order that Surgeon-General Van Reypen may retire as a rear-admiral of the upper numbers, the President will reappoint him Surgeon-General of the Navy when his term of office expires on December 18th. On that date he will lack about three months of the necessary forty years of creditable service allowing him to retire under the Personnel Act with advanced rank from that held at the time of such retirement. By virtue of his present assignment as Surgeon-General he holds rank as a rear-admiral of the lower numbers, but if he was not reappointed he would return to the grade of captain. It is more than tacitly understood that Admiral Van Reypen will apply for retirement as soon as he may under the provisions of the act referred to. Upon his retirement Medical Inspector Presley M. Rixey will be appointed Surgeon-General of the Navy.

McGill University.—The Phi Beta Pi Medical Fraternity of McGill held an installation this week, followed by a dinner provided by the medical students, at which addresses were delivered by Dr. Pray of Ann Arbor, Mich.; Dr. Mayer of the University of Western Pennsylvania, Pittsburgh, Pa.; Dr. Tidd of the Rush Medical College, Chicago; and Dr. Thomas of the Starling Medical College, Columbus, O.

Woman in Medicine.—The woman doctor in England has all her struggles before her. Recently the governors of the Macclesfield Infirmary appointed a Miss Murdoch Clark as junior house surgeon. Six honorary surgeons thereupon resigned. Recently the governors decided to ask her to resign, giving her a year's salary.

She replied that she was fighting the battle of medical women and declined to resign. The governors adjourned.

North Texas Medical Association.—This association met at Greenville, Tex., on December 10th, 11th and 12th. The Sections on Obstetrics and Gynecology, Surgery, and Practice were well represented and a number of interesting cases and papers presented. On the last evening of the session the physicians of Hunt County gave a reception to the visitors and their families.

Tuberculosis in Connecticut.—An organized movement is on foot to induce the cities of the State of Connecticut to enact local legislation to stamp out pulmonary tuberculosis. The ordinance which is being recommended to the municipalities set forth that tuberculosis is an infectious and communicable disease; directs each physician to report in writing to the local health authorities all cases of the disease which he is called to attend; makes it a misdemeanor to permit a room which has been occupied by a consumptive to be again occupied until it has been disinfected under official supervision; and provides that when a person dies from tuberculosis the City Health Officer shall be immediately notified by the undertaker in charge of the body. The Board of Health of Waterbury has already endorsed the proposed legislation and other cities have the measure under advisement. The State Board of Health has already established rules requiring cases of tuberculosis to be reported to the town health authorities, but the Board has no jurisdiction over cities which have Boards of Health. The State Tuberculosis Hospital, which is being built on Cedar Hill, in the suburbs of Hartford, and for which the recent General Assembly made an appropriation, is approaching completion.

The Western Surgical and Gynecological Association.—The eleventh annual meeting of the society will be held at the Great Northern Hotel, Chicago, on December 18th and 19th. A most interesting program has been prepared, which includes symposia on fibromyoma of the uterus and on prostatectomy. A. F. Jonas, M.D., of Omaha, Neb., is the president. A banquet will be given the visiting members by the Chicago members of the society on the evening of the 18th.

CORRESPONDENCE.

OUR LONDON LETTER.

(From our Special Correspondent.)

LONDON, November 30, 1901.

THE MEDICAL PARLIAMENT IN SESSION — THE CAUSATION OF CANCER: A NEW THEORY—THE IMPROVEMENT OF THE HUMAN RACE.

OUR Medical Parliament is now in session and as usual is giving a highly successful representation of a new version of "Much Ado about Nothing." For loquacity, waste of time, and legislative futility, our General Medical Council could hold the championship against any body appointed for the discharge of public duties in the world. There are no questions of any but local interest before it, and I will therefore not bore your readers with any account of the proceedings.

Last week I wrote about a case of cancer supposed to have been cured by an application of infusion of violet leaves. The case, as regards the sequence of facts, is a genuine one, but for the explanation of the facts we must wait for the *dénouement*. In the meantime an account of a new theory of cancer may be of interest. It was put forward at a meeting of the Leeds and West Riding Medico-Chirurgical Society two or three weeks ago by Dr. James Braithwaite, a gynecologist of some repute who may be known to many in connection with a "Retrospect of Medicine" which has appeared under his name for many years. He evidently believes that he has discovered the cause of cancer, and he is very much in earnest about the matter. The secret which so many men have shunned delights and lived laborious days to wrest from Nature may be told in one word, *salt*. In these days of fierce publicity, when every immature concept of the scientific mind is forthwith proclaimed to the world as an epoch-making discovery, the shifting currents of medical thought must cause hopeless perplexity in the mind (when he has any) of the "man in the street." Only a few months ago we were told on high scientific authority that salt was the elixir of life, and this announcement created such a demand for it that extra supplies had to be arranged for in clubs, hotels and restaurants. Fortunately Dr. Braithwaite's theory has not yet got into the newspapers, or there will be a terrible "slump" in the simple condiment which has scarcely yet lost the freshness of the blushing honors lately thrust upon it. Dr. Braithwait's theory is that excess of salt in the diet is one of four factors which originate cancer. It is the essential one, but inoperative without at least one and probably two of the others. The other factors are (1) an overnourished condition from more food, and especially more meat, than is needed by the organism; (2) an impure condition of body owing to non-use and non-oxidation of the food which has been taken; this condition is present in old age, in persons who lead indolent, easy and indoor lives, and locally in organs whose active functions have ceased; (3) a fourth factor is some local irritant or stimulant, such as friction from the stem of a pipe, or irritation from some micro-organism, of which no one is actually specific, or ovarian stimulation in the case of the breast. Of these the first must always be present and probably in some the fourth, and also either the second or the third, but not both of them. These factors being in existence the disease may be started in perhaps one epithelial cell, or in a mass of cells which grow individually larger, and change the nature of their protoplasm, for a cancer cell will not stain with Congo red whilst an epithelial cell

takes the stain deeply. The cell becomes a different being, with often more than one nucleus. Dr. Braithwaite says his theory was originated in his mind by the observation that cancer of the uterus was seldom or never met with amongst the numerous Jewesses attending the Gynecological Out-Patient Department of the Leeds Infirmary (only one case in ten years). The experience of the London Hospital where there is a special Hebrew Department is the same (only one case in five years, against 178 amongst Gentile women). The difference in diet between Jews and Gentiles is mainly the absence of bacon and ham in the diet of the Jews; and as the pig is the only domestic animal in which no case of cancer has ever been met with, he argues that it must be the salt and not the flesh which is to blame.

The distribution of cancer in England appears to Dr. Braithwaite to strengthen the case against salt, for wherever there is much cancer there is much meat-eating, and much meat means much salt. His teaching might be expressed in the formula "No salt, no cancer." "Cancer houses," as to which there has been a good deal of investigation during the last two or three years, are in Dr. Braithwaite's opinion merely houses where there is accommodation to keep a pig! Thus does a man, even one of knowledge and experience, who is thoroughly possessed by a theory, allow himself to be carried away by it into the depths of absurdity. It would be in vain to point out to such a one that cancer is common among the vegetarian millions of India; the reply would be that they take salt when they can get it. What are the unhappy people to do? Some years ago the doctrine was promulgated that the want of salt was the cause of the prevalence of leprosy in India. The rival theorists may be left to settle their "facts" as to the use of salt by the natives; but is a Government which professes to be a model of philanthropy—duly tempered by political economy—to endeavor to check the ravages of leprosy by sowing the seeds of cancer among the vast population under its rule? It is a matter of common medical experience that cancer spares Jews no more than it does Gentiles. If it be a fact—and this is, to say the least, very doubtful—that Jewesses are less liable than Gentile women to uterine cancer, this may perhaps be accounted for by the strictness with which even those of them who practise no other precept of their religion obey the ordinances as to "uncleanness." This is at least as plausible a theory as their abstinence from pork.

In the Huxley Memorial Lecture recently delivered before the Anthropological Institute, Mr. Francis Galton, who has done much careful work in regard to heredity and cognate subjects, outlined a plan for the improvement of the human race, or as he expressed it, the "possible improvement of the human breed under the existing conditions of law and sentiment." The essential point in his discourse was a demonstration of the advantages that would accrue to the State from the selection of men and women likely to produce a population of the highest class, and the presentation to them of bonuses and rewards of various kinds to induce them to intermarry. It is Walt Whitman's dream of a country peopled by "magnificent persons" in a more scientific form. Discussing the question how the proposed end was to be attained, Mr. Galton said that enthusiasm to improve the race might express itself by granting diplomas to a select class X of young men and women, by encouraging their intermarriages, and by promoting the early marriage of girls of that high class. The means that are available consist in dowries, where a moderate sum is important, help in emergencies, healthy homes, pressure of public opinion, honors, and the introduction of religious motives, which are very effective in causing Hindoo girls and most Jewesses to marry young. This enthusiasm to improve offspring might become in an ideal population itself a religion. He pointed out that every year in the British Islands £14,000,000 are contributed to charitable objects. A custom has existed in all ages of wealthy persons befriending poor but promising youths; this might be extended to young and promising couples. Again, it was usual among large landowners not to proceed on the back-rent principle, but to select the worthiest for tenants, and give them good cottages at low rents. The result was that the tenants and servants were of a finer stamp than men in similar positions elsewhere. It might easily become an avowed object of noble families to gather fine specimens of humanity round them, just as it was to produce fine breeds of cattle and so forth, which were costly in money but repaid in satisfaction.

The improvement of the "human breed" by State-regulated sexual selection is not a new thing. It has been tried, if I mistake not, more than once by sects of religious or other cranks in the United States, without any particular result. Of these experiments Mr. Galton seems to have made no mention. Nor did he say anything of the old King of Prussia, the father of Frederick the Great, whose ambition it was, in the words of Dr. Johnson, to "propagate procerity." To this end he bribed or kidnapped tall men from every country in Europe and thus formed a regiment of big grenadiers. These giants he mated with the tallest women he could find. The result of the experiment was on the whole a failure. The time may come when men and women may be "bred" like cattle; but that time is not yet—at least in our "Sleepy Hollow" of a country.

SOME REFLECTIONS ON OSTEOPATHY.

To the Editor of the MEDICAL NEWS:

DEAR SIR:—A man who represented himself to be from some Press Association called on me a few days ago, claiming to have some information concerning the practice of "Osteopathy" which he said would be of the greatest

value to the medical profession. He designated this practice as a gigantic fraud and an imposition, and a menace to the public health. In this I agreed with him. He offered to sell this evidence to me, and failing in this, wanted my moral support. I told him any effort to protect the community from the evils of this and kindred practices would have not only my moral support, but my active support as well at the proper time. I understand this person is visiting physicians, asking signatures to a petition of some kind, and soliciting subscriptions, using my name and showing a letter of introduction to me.

I know nothing of this person or of the association he represents, and, while I do not desire to cast any reflections on him or impugn his motives in any way, I want to say that he has no authority to use my name. I want to ask the members of the medical profession to be careful in signing any petition which may be presented, and in making subscriptions until they are certain the cause is a worthy one, and the person representing it is authorized by some organization or person other than himself to represent it.

New York, Dec. 3, 1901. FRANK VAN FLEET.

TRANSACTIONS OF FOREIGN SOCIETIES.

French.

RUPTURE OF THE SPLEEN—CHRONIC LEAD-POISONING—FUNNEL-SHAPED CHEST AND HEREDITARY SYPHILIS—TUBERCULOUS PSEUDORHEUMATISM—JACKSONIAN EPILEPSY — PROSTATECTOMY — ASTRAGALECTOMY—APHASIA.

BOINET, at the Academy of Medicine, October 29, 1901, gave the details of five cases of rupture of the spleen, occurring among malarious patients under various circumstances, namely, onset of intermittent fever, traumatism, etc. The cause of rupture, which may be termed spontaneous, which one observes during an attack of fever is necessarily difficult to fix. Sometimes this accident is favored by the softening with increase in size or the simple enormous distention of the organ. Sometimes it is due to a splitting of the envelope of the spleen, which is thin and hard. Adhesions, if numerous, on a malarious spleen between the diaphragm and the stomach equally tend to rupture of the organ, partly on account of the traction they exercise and partly by the fixation of the spleen, which does not escape in this manner the full result of any injury. In all of his five cases death followed a few days after the rupture.

VARIOT, at the Medical Society of the Hospitals, October 25, 1901, read notes of a case of chronic lead-poisoning due to a pewter drinking-cup which contained a large percentage of lead in its metal. The patient was a child who presented complete paralysis of the lower extremities and a muscular weakness of the upper extremities. The sphincters were unimpaired. On examination it was found that the gums showed a well-marked line blue characteristic of lead-poisoning. The diagnosis of lead paralysis was therefore easy and was explained by the fact that the child had used for a long time a cup made of pewter, which contained almost 75 per cent. of lead. It is exceedingly likely that a solution of a small quantity of this lead by the more or less acid fluid used in the goblet was the real cause of the poisoning. After removing the cause recovery occurred in a short time. The extensor muscles remained, however, rather weak for a longer time. The author arrives at the conclusion that, in all public institutions which still use pewter mugs, care should be taken to avoid such as contain a large amount of lead. It would be better still to cease their use entirely.

GAUCHER presented a young man who had several ulcerations on the legs and at the same time a deformity of the chest, familiarly called funnel-shaped chest. In addition he had abolition of the reflexes at the patella and a diminution of the reflex of the pupil to light. The cause of all the symptoms was really obscure. The individual did not present a single other evidence of nervous disease. He was, moreover, not actively syphilitic. Very likely it was a case of hereditary syphilis with the above nervous symptoms.

GALLIARD brought forward a young girl, sixteen years old, who had been afflicted during the year with a chronic pulmonary tuberculosis aggravated by an acute inflammation of the deposits in the lungs, especially in the pleura, and a peritonitis with possibly a meningitis. Later there appeared a tender swelling over the joints of the fingers, toes and knees. While this pseudorheumatism was developing there also appeared diaphragmatic pleurisy on the left side. The heart, however, escaped entirely. All these conditions ended in resolution. A collection of pus, however, appeared in the thigh, which seemed to play the part of an "abscess of fixation." Later the young patient left the hospital in about the same state as she entered it, namely, with a tuberculosis localized at the apices of both lungs.

PITRES, at the Academy of Medicine, November 5, 1901, gave the following points on the value of Jacksonian epilepsy in the diagnosis of lesions of the cerebrum. He said at the time that it is well established that these lesions are able to provoke a partial epilepsy, although they do not in themselves possess a definite location, because they may be situated within the motor area or outside of it. In either case it does not appear that the characteristics of the convulsions are modified to a large degree. On the other hand it would not be right to pretend that partial epilepsy has no diagnostic value. If it occurs with definite features, if the motor aura is well localized, if the convulsions begin distinctly at the periphery and work slowly toward the center, if the patient is conscious and can give information as to their point of origin and the manner of their development, if they are accompanied by pure monoplegia or by definite other paralysis, there will be very great probability of making a correct diagnosis as to the location of the lesion. In such a case it will usually be found near the cen-

ter which is first affected, but it is by no means certain, especially if the lesion is a tumor. There is another fact which we must acknowledge, namely, that the entire number of facts thoroughly settled is small, and that after all we do not yet understand what is the true origin of Jacksonian epilepsy. Ordinarily we reason that the cause may be single, whereas probably it is multiple. It is somewhat likely that the lesions depend upon a discharge from the cortical centers, as Jackson originally taught. In other cases, however, as is claimed by Adamkievicz, the fit is due to direct compression or irritation of the subcortical centers. It is therefore apparent that all these facts cannot be explained by any one theory, and, indeed, no two theories together account for them all. One wishes one could understand how these epileptic convulsions can develop with or without lesions of the motor zone, and how they can be cured in a few cases by decreasing the intracranial pressure by a simple trephining, while they can in other cases continue to act, although all the cortical centers which correspond to the first symptom have been removed. With these points in mind, it is not surprising that often when one opens the skull and expects to find a definite cause of the trouble present itself within the field of operation, one should be mistaken and discover nothing that calls for operation.

ALBARRAN, at the Surgical Society, October 30, 1901, read some new statistics on the subject of subpubic prostatectomy. He has found four hundred records. He has himself performed the operation seven times with one death, but he has ceased to employ this method because the results do not appear to him to be satisfactory. The perineal operation, on the other hand, he considers much better and indicated in the majority of cases of hypertrophy. It is contra-indicated only when there is severe cachexia, pyelonephritis of both sides, periprostatic abscess or severe infection of the bladder. This form of operation is usually thought less dangerous. Of sixteen cases which he has treated in this way, none have died, although they were all old men and in poor general and local condition for the most part. Eight are absolutely cured, three are still getting better and four others were operated on so recently as to make a present prognosis impossible. The sixteenth patient of this series he has not seen since operation.

WALTHER, in behalf of Brossard (Cairo), read notes of a case of removal of the astragalus for an old dislocation. The patient was a woman, forty-two years old, and was seen by the surgeon at least one month after the accident. The dislocation was forward and outward. Removal of the bone was proposed and accepted by the patient. After the operation was over it was noted that a small fragment of the bone belonging on the posterior and internal surface was lacking. The result, however, was excellent and there was no difference in the use of the limb nor in the imprint of the foot, as compared with the other side. Brossard offered the opinion that this happy outcome was probably due to the fragment of the bone which remained behind. The X-rays tended to bear out this supposition. On the other hand he could not accept without some reservation the theory that so comparatively small a part of so important a bone could be responsible in itself for the good result.

TOUCHE, at the Society of Biology, November 2, 1901, showed a series of charts on which he had plotted various lesions found in a number of patients who had had right hemiplegia and aphasia. Examination of his charts seems to prove that lesions of the island of Reil play a very important part in the production of pure motor aphasia.

SUBSTITUTION.

To the Editor of the MEDICAL NEWS:

DEAR SIR: It has been a source of much satisfaction to us to note the strong attitude which the MEDICAL NEWS has taken against the substitution and adulteration evil, as evidenced by recent editorials on this subject. To give you an example of the extent to which these nefarious practices are being carried on, we would say that we recently unearthed in Detroit a conspiracy in which certain criminals, trading under various names, were selling to druggists bogus products, put up in counterfeit boxes, in place of a number of our products.

How these so-called medicines were put up by them is clearly shown by the following answers to questions given by witnesses in hearings before the Court and the prosecuting attorney.

John A. Jenkins, an employee of L. J. Fulmer:

Q. How did you know what went into the boxes?

A. I didn't know.

Q. Then how did you know what labels to put on these boxes?

A. Well, I didn't know that either.

Q. Then you don't know but that you have got phenacetin in sulfonal boxes?

A. I don't know that either.

Q. Nobody told you?

A. Nobody told me.

Charles A. Bailey, connected with U. S. Treasury Department:

Q. What was the conversation?

A. We were talking about the price of phenacetin and the competition going on. If I might be allowed to explain my visit to Fulmer you would understand the case better, and I do not think that it would hurt this case any. . . . Asked him if he did not fear they would injure his business by underselling, and he told me he did not; he thought he could undersell all of them.

Q. How, or by what means did he state?

A. Well, he did not sell a "straight" phenacetin.

Q. What did he say he mixed with it, if anything?

A. This gentleman has just given it a new

name—acetanilid, I have called it, but he put the accent in a different place.

Dr. H. Schweitzer, Expert Chemist:

Q. Are the contents of the larger package phenacetin Bayer?

A. The larger—of the larger box. They are not either. It is a mixture of acetanilid and phenacetin.

Q. Are those labels which you found upon the two packages the genuine phenacetin Bayer label, or *counterfeit labels?*

A. They are *counterfeit labels.*

It seems incredible, but it is an absolute fact, as the books of the Detroit gang which were seized by the police show, that thousands of druggists from all parts of the country purchased these adulterated drugs and dispensed them on prescriptions. Their names are in our possession, and we shall of course proceed against them. It will be of interest to your readers to know that with the aid of the medical profession we have been in a position to trace in the past a large number of sophistications, and to show how widespread this nefarious practice is, we quote a few letters from physicians and druggists.

"Reading the article on aristol leads me to say, recently I had some from a drug-store that seemed inert, so that I got some at a very reliable store, and there was the greatest difference.

"(Signed) A. G. HITZEL, M.D.,
"9 East Parade Ave., Buffalo, N. Y."

"March 2, 1901."

"Enclosed you find a sample (bought by a patient) of aristol. As I found it did not do well on the patient I send you some of the same, and your letter mailed to me. You see I have not forgotten the matter. This was bought of ——. Kindly let me know.

"Signed) A. G. HITZEL, M.D.

"October 23, 1901."

"The enclosed was dispensed on a prescription for trional by one of our local druggists. Can you tell me what it is?

"(Signed) H. A. FRANCISCO, M.D.,
"99 Center St., Rutland, Vt.

"March 13, 1901."

"This day I send you another sample of what is said to be phenacetin; it came from a bottle I should say held a pound, and it has no mark on it. I can purchase one ounce for 10 cents, so I can hardly believe it is pure. Send me a sample of pure, and give me price per lb., as I wish to use the pure in a tablet.

"(Signed) D. E. CAREY, M.D.,
"206 E. Water St., Elmira, N. Y.

"March 15, 1901."

"Last month my wife was in New Orleans and had occasion to purchase some trional which she frequently takes for insomnia. I enclose you one of the powders which she purchased, believing it is not trional, but a spurious article which is being dispensed under that name. My wife took only one of the powders; she noticed the difference and was afraid of the others. The one she took had no effect.

"(Signed) JNO. E. THATCHER,
"201 Patterson Ave., Dallas, Texas.

"March 10, 1901."

"I enclose a powder dispensed as sulfonal. The taste of it seems to me much sweeter than other earlier samples, and the effect not so reliable. Is this genuine?

"(Signed) Ross P. Cox,
"Rome, Ga.

"November 10, 1900."

"I enclose you two sides of 1 oz. package of sulfonal I purchased in October, '99. I put up 24 powders of same for customer October 18th, and she informs me that they are not like she has been getting from a Chestnut Street firm, and considers mine as not being sulfonal *pure.* I have tasted one of my powders and one of the others and find them different. My sulfonal is not like the last box I received from the same firm and I am at a loss to know how it was possible to get your sulfonal that was not O.K. I send you two powders, one from my box and one from the other firm, and can you tell me how I got sulfonal in the package that is not pure? I cannot think it possible that it was changed in my store. I have inquired from each of my clerks and they positively assert that they have not touched it. The powder returned to me certainly contains acetanilid, and I ask if it is possible that such was the case with the package when it left your place.

"Your interest in this matter will be much appreciated.

"(Signed) J. G. HOWARD,
"Broad and Fairmount Ave., Phila., Pa."

An analysis of the contents of the boxes and of other boxes purchased in the open market at different times shows that acetanilid is sold by druggists as phenacetin and also as trional and sulfonal; that acetanilid is mixed with either phenacetin, trional, or sulfonal in proportions up to 50 per cent., and sold as the genuine article. A mixture containing caustic soda, a large percentage of organic bodies insoluble in ether, etc., is sold as aristol. As is well known, caustic soda is in itself a pronounced irritant, and, when in combination with an iodine-containing compound (such as the fraudulent aristol alluded to), it acts even more injuriously by liberating the iodine much more rapidly and in larger quantities than occurs when pure aristol comes in contact with the secretions of a wound. The large amount of iodine thus given off acts not only as a local irritant, but also as a systemic poison.

Both the physician's reputation and the welfare of his patient are at stake in this matter. When, therefore, we protect ourselves against these criminal practices we believe that we are equally protecting the medical profession, to whose approval our products owe whatever popularity they possess.

We, therefore, appeal to your readers for their support by urging them to patronize only those druggists whom they know carry in stock the preparation prescribed, and by communicating to us the name of any pharmacist whom they have discovered in the act of substitution.

We would request physicians who suspect the quality of drugs purporting to be of our manufacture to send us the original packages with contents for analysis. We shall replace the goods from our own stock and report results to them, so that they may protect themselves and their patients against frauds of this kind.

FARBENFABRIKEN OF ELBERFELD CO.

New York, November 26, 1901.

SOCIETY PROCEEDINGS.

NEW YORK STATE MEDICAL ASSOCIATION.

NEW YORK COUNTY BRANCH.

Stated Meeting Held November 18, 1901.

The President, Parker Syms, M.D., in the Chair.

Rectal Carcinoma.—Dr. John F. Erdmann presented a specimen of carcinoma of the rectum from a patient seventy-eight years of age. The general condition was fair, and though the patient's age seemed a contraindication, it was thought advisable to remove the malignant growth in order to relieve symptoms and if possible prolong life. The tumor was excised without difficulty and recovery was very satisfactory.

SYMPOSIUM ON TYPHOID FEVER.

The first paper was read by Dr. James Ewing on the subject of Serum Therapy in Typhoid Fever. This paper will appear in a subsequent issue of the MEDICAL NEWS.

Typhoid Fever in New York City.—Dr. John H. Huddleston read a paper on the epidemiology of typhoid fever in New York, and said that when a case of typhoid fever is reported to the New York Board of Health an inspector is sent out to inquire into the circumstances of the case. The subjects with regard to which questions are asked are especially the source of the family milk supply, the sanitary conditions of the neighborhood with special reference to the occurrence of typhoid fever; the possibility of contact with other cases of typhoid; and, finally, with regard to bathing along the water front of the city, to which cause some cases of typhoid fever seem directly attributable.

Typhoid Statistics.—The reports of the Board of Health show that typhoid fever is constantly present in the city. During March of the present year the minimum number of cases reported weekly was seven, while 170 cases were reported in one week of September. The statistics for a number of years taken together show that the disease is comparatively light in March, April, May and June; that it rises markedly during July and August and reaches a maximum in September and October. The decline begins in November and reaches a minimum in February and March.

Origin of Cases.—Taking the report of 755 cases investigated, in 635 the patients had not been outside the borough of Manhattan for a considerable time prior to the contraction of the disease; 120 of the patients had been outside of the city and might have contracted the disease elsewhere. Taking the opinion adopted by the Clinical Society of London, which has the approval of Dr. Osler, the incubation period of the disease is from eight to twenty-two days. According to this at least 113 of the 120 who had been outside the city were infected before arrival here. Ninety of the cases were ill when they returned to the city for treatment.

Causes of the Disease.—In 34 cases the patients reported that they had been bathing along the water front, and in some at least of these cases there was good reason to think that the contamination of the river water with city sewage had provided the infectious material swallowed during bathing. Though it is often stated that typhoid fever is more frequently due to milk, and especially to the poorer grades of milk, it is extremely difficult to trace any direct connection between the milk supply and most of the reported cases of the disease. In a large number of cases affected families used condensed milk, and some of the patients used no milk at all. A small number of cases occurred among laundry employees. It seems clear in these cases that the disease developed as the result of contagion from the contaminated garments of typhoid fever patients. Seven nurses developed the disease; six of them while nursing private patients and one of them in hospital practice. One doctor developed the disease, evidently contracted from a patient whom he was attending. Taking a definite part of the city, it is interesting to note how the cases of typhoid fever are grouped. The distribution is rather uniform, not a single street escaping without its case. One street showed twelve cases in about two years. This was all the more striking, as the streets just above and below had seven and eight cases respectively, and it seemed as though something in the surroundings must favor the occurrence of the disease; but investigation showed that there was no common ground for the etiology of the disease. Six out of the twelve cases on this street developed as the result of infection outside of the city. Only three of the families in which typhoid fever developed obtained their milk from the same source. This same accidental grouping of cases was noted in other parts of the city. On the other hand cases sometimes develop in groups as the result of contact without proper precautions. In one neighborhood on the East Side 27 cases developed along one street, and a large number of these cases were due to the fact that most of the members of two families contracted the disease through carelessness. It is evident, then, that so far as regards New York, no definite cause can be found for many of the cases

of typhoid fever. There is some underlying condition as yet unknown, to which most cases seem to be due. No conditions of locality, nor of water, nor of milk supply enable us to decide the origin of these cases. The importation of cases from without and subsequent contact with others in the city undoubtedly **has** something to do with its continuance and spread, but this does not acount for all of the cases. The investigation of this subject of the etiology of typhoid fever remains, then, as one of the most important problems to be dealt with in the city's sanitation.

The next paper on the program was read by Dr. Robert Abbe on the Surgical Complications of Typhoid Fever. This paper will appear in a subsequent issue of the MEDICAL NEWS.

In the absence of Dr. Hermann M. Biggs, Dr. Alexander Lambert, at the invitation of the President, made some remarks on the clinical diagnosis of typhoid fever.

Reasons for Difficulty of Diagnosis.—Dr. Lambert said that some of the reasons for the extreme difficulty often encountered in the diagnosis of special types of typhoid fever had been brought out this evening by Dr. Ewing in his discussion of the different bacteriological peculiarities of the typhoid bacilli. Typhoid infection is not a single process and the infectious material in different cases is not always similar. Some of the symptom-complexes that are classed as typhoid fever are probably not true typhoid, but a bacillus-coli communis septicemia. Among the German soldiers who took part in the siege of Paris in 1871, typhoid fever was very common. It had many of the classical symptoms of the disease, but ran an almost absolute afrebrile course, the maximum temperature being seldom above 100° F. Soldiers were very sick with the disease, and yet had a temperature of only 99° F. It would seem that the more or less exhausted condition of the men after their severe campaign reacted with some peculiarity of the special bacillus of the epidemic to produce this anomalous type of the disease. In a series of cases reported some time ago among the nurses at a hospital the fever, though typhoid in many of its symptoms, lasted only two weeks instead of the usual twenty-eight days, and the fever fell by crisis instead of by the normal lysis. There were many severe complicating symptoms during the epidemic that were surely typhoid in origin, though the general affection ran such an anomalous course.

Pathognomonic Signs.—For the diagnosis of typhoid fever the important things are the symptoms that arouse suspicion of the character of the disease early in its course. Of these the most important is the extremely low tension of the pulse, which is characteristically different from the bounding pulse of pneumonia, the running pulse of sepsis or the wiry pulse of abdominal affection. Under the finger the pulse of typhoid fever lacks tension to a remarkable degree and can be obliterated with extreme ease. During the first week a pathognomonic clinical symptom is the ladder-like rise of temperature, which can be readily recognized if the temperature record be kept. Very early in the disease there occurs a marked benumbing of the special senses, all of the senses being affected and in at least 90 per cent. of the cases the patients are much more incapable of being aroused to interest in anything than can be accounted for by their physical symptoms. The name of the disease is, of course, drawn from this characteristic mental hebetude, and it is a striking symptom. Patients dream badly and, though restless, pay little attention to their surroundings. It is from a combination of all the symptoms and not from any one pathognomonic sign that typhoid fever must be diagnosed. It was hoped that the Widal reaction would prove the touchstone for typhoid diagnosis, but it does not occur early, is at times entirely absent, and not infrequently does not occur until convalescence has set in. With regard to the Widal reaction one must be grateful if one finds it, but one must learn to get along without it. At first it was said that 96 per cent. of the cases of typhoid fever showed the Widal reaction. Great variations in opinion exist as to the time that may be allowed to elapse before the characteristic clumping occurs and yet this sign is supposed to show a positive reaction. Where the Widal test is positive it is pathognomonic; where it is negative it means nothing.

Microscopical Confirmation.—The microscope can be of great service in confirming the diagnosis of typhoid fever in a suspicious case or at times of reversing it. The malarial organism should always be looked for and the leucocyte-count should be made. The differential count of the leucocytes is an important proceeding in typhoid diagnosis. In ordinary blood 66 per cent. of the white cells are polynuclear leucocytes; in the blood of the typhoid-fever patient 60 per cent. of the white cells are mononuclear leucocytes. This complete reversal of the proportion of mononuclear and polynuclear leucocytes present is pathognomonic of typhoid fever. In one case reported to the Board of Health as possible typhoid fever the Widal test was negative. A blood-count showed that there was a marked leucocytosis present, some 22,000 white cells. It was suggested to the attending physician that an abscess might be present in the case. He telephoned later that an ischiorectal abscess had been found and opened and that the patient's fever had come down at once and his general condition improved. Dr. Delafield used to remark that nothing was too irregular for typhoid fever. Notwithstanding all the advances in diagnosis in recent years, typhoid fever remains one of the most trying problems in diagnostic differentiation. Too great confidence will surely lead to mistakes.

Treatment of Typhoid Fever.—Dr. A. A. Smith said that there is no specific for the treatment of typhoid fever, and the most interesting recent work that concerns the specific care of the disease is the manufacture of prophylactic serum. The employment of this is as yet too recent and

the theories on which it is employed too unsettled for the practitioner to find anything very satisfactory in it. With regard to the abortive treatment of typhoid fever, Dr. Smith does not think that any one has ever succeeded in causing typhoid fever to run a shorter course by any remedial measures. Typhoid fever is sometimes aborted, but its abortion is due not to the drugs employed, but to natural agencies whose mode of action we do not understand. With regard to the treatment of symptoms in typhoid the first thought is always the fever. To combat this baths are employed. They seem to have an effect in neutralizing the toxins of the disease which act upon the heart muscles. It is not probable, however, that this tonic action on the heart is different from that of the stimulation of the nervous system. Dr. Smith's personal preference is for the bed-bath rather than the tub-bath. In his wards at Bellevue Hospital and in his private practice the following method of bathing is used almost exclusively: A rolled blanket is placed on each side of the bed and over these a large rubber horse-cover is placed. Pillows are placed at the head and foot of the bed, beneath the rubber blanket, and into the trough thus formed water is poured, at first at a temperature of 90° F., not at 70°, as sometimes suggested. Cooler water is then slowly added. In the meantime the patient is sponged off, care being taken, however, not to produce any sense of discomfort. This method has many advantages, the chief of which is its convenience and inexpensiveness. A horse-cover can be obtained for a couple of dollars. Its employment does not seem so formidable to the patient and so it is apt to be used earlier and oftener in the case than a more elaborate bathing apparatus, as very little movement is required to give the patient the bath. This is of itself a valuable consideration.

It is a question if the complete reduction of fever is to be desired. Fever stimulates cell action and so enables the organism to resist the toxic effects of the disease upon the system. The temperature should not be reduced below 101° F. in the rectum. Baths are the best agent for the reduction of fever, but during the third week great care should be exercised in their employment. Very rarely should more than three be given in the day and at times one will suffice, even though patients may be somewhat restless. As a rule in patients over fifty-five years of age the bath should never be given at a temperature below 80° F. In older people and in children a wet pack at about 60° F. is a better method of reducing temperature than a bath. In general, age is always an indication for the modification of hydrotherapeutic measures in typhoid fever.

Constipation.—At the beginning of typhoid fever a mercurial purge is the best, and calomel seems the most favorable form for its administration; but it should not be repeated more than twice at the beginning of the disease. Then, if constipation continues some other laxative, as cascara or a mild saline, should be administered. After the eighth to the tenth day of the disease no laxative should be employed, the physician should rely upon enemata to move the bowels. Dr. Smith believes that the use of large injections favors perforation. Enemata should be employed, but not in greater amounts than a quart of liquid, and usually a pint suffices for the purpose. They should be given at about the body temperature; besides removing decomposed material, they help very materially to get rid of flatus. Despite the prejudice against them that has developed in recent years, Dr. Smith does not believe that the use of the coal-tar antipyretics should be entirely abolished. They should be given in small doses. Phenacetine in combination with spirits of ammonia is the best one. Their special indication is for nervous discomforts and headaches. They should not be used with the idea of lowering temperature. Whenever the patient's nervous symptoms are not relieved by the bath, the coal-tar products combined with some heart stimulant should be used. This rule is especially to be observed during the first stages of the disease. If the patient becomes restless during the third week, alcohol and the heart stimulants should be employed freely. The administration of alcohol should not be a routine practice in typhoid fever, but it should be given as indicated. If patients were alcoholic before the development of the typhoid, then alcohol must be used early in the disease. In other cases the indication for its administration is a rise in the pulse rate to 120, especially if the pulse becomes variable or intermittent. Other indications are the development of apathy with subsultus tendinum or carphologia. The most important of the heart stimulants is strychnine. This does not seem to act directly upon the heart, but on the nerves supplying the heart. Another important heart stimulant is caffeine; and, where strychnine or caffeine fail to stimulate, oil of camphor should be used hypodermically. In general camphor should be used much more than is at present the custom.

Intestinal Hemorrhage.—There is no specific for the treatment of intestinal hemorrhage. Dr. Smith believes very little in the efficacy of the so-called hemostatic drugs. The best means to stop the bleeding is to produce absolute quiet by the administration of opium and to give as little food as possible, thus keeping the bleeding vessel at rest until Nature has sealed it. The orthodox treatment of ice-bag to the abdomen in this case Dr. Smith believes to be a mistake. Application of cold favors the continuance of bleeding from the intestine by driving the blood from the vessels of the abdominal wall to the internal viscera.

Diet.—The most important thing is a nearly exclusive milk diet. To this should be added some salted liquid. Three pints of milk and as much water constitute an excellent dietary so far as liquids are concerned. Where milk can not be taken, eggs may be employed. Broths should usually be added to the dietary in order

to avoid the monotonous effect of milk alone. An absolutely fluid diet should be maintained for at least eight or ten days after convalescence is established, that is, after the patient's temperature has reached normal. Dr. Smith is opposed to any more liberal diet. There is a tendency to think the typhoid-fever patients would be better if a more varied diet were allowed. Some physicians have even counseled the admission of meats and certain vegetables, in a finely-divided state of course, to the ordinary dietary.

Preperforative Stage.—In the discussion Dr. Kinnicutt said that one of the most important things in the present interest in typhoid is the question of the early recognition of intestinal perforation. Cushing of Johns Hopkins has described a preperforative stage from the time when the serosa begins to form adhesions until it breaks down as the result of the ulcerative invasion. The most important warning symptoms of perforation are abdominal pains, localized tenderness and leucocytosis. Subjective symptoms, especially if localized, must always give rise to apprehension. A sudden development of leucocytosis with localized tenderness always means threatened perforation. To these signs Dr. Kinnicutt adds another observed in the wards of the Presbyterian Hospital. This is a localized, fine peritoneal crepitation, similar to that occurring in the pleura or pericardium, which can be detected by careful auscultation over the entire abdomen. If this sign is obtained the diagnosis of threatening perforation is made. If there be tympanites and rigidity of the abdominal muscles and if abdominal breathing be interfered with, then, of course this crepitation will not be obtained. It is due, as in the case of the pleura and pericardium, to the rubbing of inflamed serous surfaces over one another. Dieulafoi states that in his experience perforation of the intestine with extravasation of the intestinal contents is invariably followed by a fall in temperature, but in five cases in Dr. Kinnicutt's experience at the Presbyterian Hospital, this did not occur. The temperature was not affected in any of the cases, although in all the diagnosis of perforation with extravasation was confirmed by operation or autopsy.

Unusual Complications.—Dr. Nathan Brill reported certain unusual complications of typhoid fever. In an epidemic of the disease at Mt. Sinai Hospital among the nurses, 22 of the hospital attendants suffered from the disease and all of them had the infection in virulent form. None of the cases proved fatal, but many suffered from peculiar complications. In three cases otitis media developed; in two there were symptoms of mastoiditis. Under the use of a Leiter coil this subsided. In two cases in private practice Dr. Brill has seen the development of central deafness as a complication of typhoid fever. This complication is not mentioned even in Curschmann's article on typhoid fever in Nothnagel's system.

Surgery of Typhoid Fever.—Dr. Murray said that if Dr. Smith's diet regulations were followed there would be less need for surgery in typhoid fever. He considers the crepitation sign as described by Dr. Kinnicutt as of very great importance. Operation for typhoid perforation will very often be successful if performed during the first eighteen hours after the accident. The evident duty of the medical man is to call the surgeon in early. Thirty-two per cent. mortality means a great saving of patients when we consider that formerly just so many of them perished. Dr. Finney's suggestion of a small opening under cocaine for exploratory purposes is very useful. If perforation is found, general anesthesia should be employed.

BOOK REVIEWS.

THE PATHOLOGY AND TREATMENT OF SEXUAL IMPOTENCE. By VICTOR C. VECKI, M.D. Third Edition. W. B. Saunders & Company: Philadelphia and London.

THIS is one of the numerous works on this subject which have appeared within the past half-dozen years. In the main it is sound, with enough of the prurient to attract the curious, and sufficient science to satisfy the moderately enlightened.

The ideal work bearing on sexual hygiene still remains to be written, as but few of the modern writers, excepting perhaps Moll and his school, have any persuasive conception of the normal variations in the sexual life.

A GUIDE TO THE CLINICAL EXAMINATION OF THE BLOOD FOR DIAGNOSTIC PURPOSES. By RICHARD C. CABOT. Fourth Revised Edition. William Wood and Company: New York.

IN Cabot and in Ewing, American medicine can lay claim to an easy superiority in works on the pathology of the blood. This last edition of Cabot is a distinct improvement and enlargement of his last edition. In the matter of technic there is much of value that might have been added, notably in the section devoted to staining. Much can be said against the advisability of giving a great number of staining methods, yet to limit the student of hematology to two or three is, we believe, unwise. It is sufficient to say that the author's wide experience renders the book one of very great value; however, there is less evidence of wide bibliographic research that makes the book less universal than Ewing's, but it may be said that for the student of hematology, both volumes are requisite.

The illustrations have been greatly increased in number and are for the most part very excellent, although in a few instances they seem to us to be miserable, notably the small-sized reproductions of photo-fields, on pages 150, 151 and 257. Those illustrating the malarial parasite are satisfactory.

The work is so very excellent that to pick out such small defects appears to be cavilling, yet there is one serious fault, it seems to the reviewer, and that is the introduction of so much tabular

matter. The information contained in these in most cases could be conveyed in a few carefully-prepared lines. In many cases these tables are simple reproductions from original monographic studies and have no place in a book of this kind, save to fill space or to avoid the necessary work in condensation and comparison with other tables of a like or unlike character. There is also, we believe, an undue proportion of space given to the work done in certain laboratories, excellent though this may be, much of it being given with almost monographic completeness. This is, we know, an almost necessary technical fault entailed in revising old plates, the author often being compelled to interpolate new observations between old paragraphs instead of being able to rewrite the whole subject.

Apart from these minor technical matters the book is to be most cordially commended.

THE PRINCIPLES AND PRACTICE OF MEDICINE. Designed for the Use of Practitioners and Students of Medicine. By WILLIAM OSLER, M.D. Fourth Edition. D. Appleton and Company: New York.

DR. OSLER'S "Practice" has stood, since its first edition, as the highest type of a text-book of general medicine. Each succeeding edition has made it more complete and valuable and in its present and fourth edition it appears with many new and important additions.

In the preface Dr. Osler tells us that the chapter on typhoid fever has been entirely recast; the descriptions of dysentery, plague and yellow fever have been amplified and made more available, especially for the student of tropical medicine. The chapters on pneumonia, diphtheria, smallpox, cerebrospinal fever and rheumatic fever have been added to, especially along lines of diagnosis and treatment.

We are particularly glad that the chapters on gout and on arthritis deformans have been given so much careful revision. Dr. Osler is in the leading column of students in the study of joint affections and there still remains much to be made clear along these lines. The important subject of pancreatic diseases has also been almost entirely recast. The chapter on diseases of the liver has been altered but slightly; it is perhaps one of the least satisfactory chapters in the book.

The revision has been thorough and painstaking and the profession is to be congratulated on being able to possess such an admirable work in comparatively small compass.

PHOTOGRAPHIC ATLAS OF THE DISEASES OF THE SKIN. By GEORGE HENRY FOX, A.M., M.D. Parts III., IV. and V. J. B. Lippincott Company: Philadelphia and London.

IN Parts III., IV. and V. the following lesions are illustrated and described: Lupus erythematosus, lupus vulgaris, syphiloderma papulosum, vitiligo manum, lichen planus, rosacea erythematosa, alopecia areata, psoriasis nummulata, pityriasis circinata and pemphigus, sycosis, scrofuloderma, syphiloderma papulo-squamosum, eczema papulosum and morphœa.

As we have already stated in a review of the previous parts, Dr. Fox's atlas is an invaluable one and no practitioner who sees many skin lesions can justify himself in not having this excellent series of plates. Such high praise is rarely justified for a medical publication, but we believe that it is merited in the present instance.

A MANUAL OF DETERMINATIVE BACTERIOLOGY. By FREDERICK D. CHESTER, Bacteriologist of the Delaware College Agricultural Experiment Station, etc. The MacMillan Company: New York.

To those who have used Chester's work on the Coccaceæ in the difficult task of keying out unknown species, this work will prove a godsend. In fact, all bacteriologists the world over have been hoping that some one would attempt to bring order out of chaos in this difficult field. Sternberg and Migula laid the foundation and Chester has given us a completed fabric. It will undoubtedly be found faulty in places, but all manuals of this type have their faults The student of botany, the hygienist, and the physician are the richer by the publication of this important work.

MODERN OBSTETRICS: GENERAL AND OPERATIVE. W. A. NEWMAN DORLAND, A.M., M.D., Assistant Demonstrator of Obstetrics, University of Pennsylvania; Associate in Gynecology, Philadelphia Polyclinic. Second Edition. W. B. Saunders & Co.: Philadelphia and London.

As the second edition of the work of an American author this volume requires no introduction and calls only for an outline of its points of variation from the first edition. It is divided, as was its predecessor, into physiological and pathological obstetrics. Each of these parts shows enlargement and revision, particularly the pathological portion. The mechanism of labor is described quite in detail. New sections deal with the surgical and serum treatments of puerperal sepsis, a subject of which all the aspects are discussed with great thoroughness, with infant mortality, and with obstetrical pathology. Recent views regarding placental transmission of disease and the rôle of the liver in eclampsia naturally claim attention. The work is in some ways more suitable for reference than as a text-book, as the views of a number of men upon a subject or a list of methods of treatment are often given without an expression of opinion as to their relative values for which a student naturally looks to his informer. In the directions for protecting the perineum, for example, he would be left with a confused idea of a large number of methods and no indications for a choice of these. It is to be regretted that so valuable a resource as the bag of Champetier de Ribes is passed over with the remark that it is superior to that of Barnes, while the latter is

shown in an illustration and the technic of its introduction is described. Aside from these criticisms the work must be favorably regarded. As a book of reference it is useful, presenting the subject of obstetrics systematically and comprehensively. Where treatment is indicated it is usually satisfactory.

A MANUAL OF THE PRACTICE OF MEDICINE. By GEORGE ROE LOCKWOOD, Attending Physician to Bellevue Hospital, New York. Second Edition. W. B. Saunders and Company: Philadelphia and London.

THE first edition of this work, which was so favorably received, has now been thoroughly revised, many portions being entirely rewritten and numerous important sections added. It has been the aim of the author to give the principles of the practice of medicine in a concise and available form, making it a convenient book for the busy practitioner, but it seems especially suitable for use by students who require, first of all, a concise and accurate foundation of the principles of medicine unobscured by a mass of needless references and complications. The chapters upon the circulatory and respiratory systems, together with the physical signs of the same, are especially worthy of most careful study and contain many most valuable hints in diagnosis. The chapter on malaria has been entirely rewritten, the description representing the results of the latest investigations upon that subject. Stomach examinations and the analyses of gastric contents which have now come to be such an important factor in estimating digestive ability have received special attention, the material being an addition to this edition and including sections on gastroptosis, Reichmann's disease, gastric atony and gastric neuroses. The book is written in a concise, but interesting manner and deserves an even more hearty welcome by the medical profession than was accorded the first edition.

STUDENT'S MANUAL SERIES ON DISEASES OF THE SKIN: ECZEMA. By L. DUNCAN BULKLEY, A.M., M.D., Physician to the New York Skin and Cancer Hospital; Dermatologist to the Randall's Island Hospitals; Consulting Physician to the New York Hospital, Hospital for Ruptured and Crippled, and Manhattan Eye and Ear Hospital, etc. Third Edition. G. P. Putnam's Sons: New York and London.

A THOROUGH knowledge of this most prevalent skin disease is exceedingly valuable to every practitioner of general medicine. This conveniently-sized manual embodies the experience of a close observer during the past thirty years and while giving a scientific description of the disease, it has been the purpose of the author to make the book as practical as possible and most fitted for ready reference. Much space has been devoted to diagnosis, especially the differential diagnosis from other similar skin diseases, each being taken up in order and thoroughly discussed. A large number of valuable prescriptions are given under the therapeutics of the disease and detailed information offered concerning the special application of each to particular phases of the malady. The aim of the author "to lead to the ready recognition and successful treatment of the disease" seems to have been well attained.

DOSE-BOOK AND MANUAL OF PRESCRIPTION WRITING. By E. Q. THORNTON, M.D., Ph.G., Demonstrator of Therapeutics, Jefferson Medical College, Philadelphia. Second Edition. W. B. Saunders and Company: Philadelphia and London.

THE portion of this book devoted to the writing of prescriptions, Latin terminology, incompatibilities, dosage and administration shows the hand of one who is not alone familiar with medicine, but also with pharmacy. But the main bulk of the work is occupied with an alphabetical list of official and unofficial drugs and their preparations, with doses and slight further information. There is too literal translation between the metric and English systems, as, for example, the dose of ipecac is given as ½ to 31 grains, and that of compound powder of jalap as 2.59 grams. The dose of the fluid extract of digitalis is put as $^1/_{10}$ of the tincture, though the fluid extract is only 6⅔ times as strong. The formula given for Warburg's tincture is not that of the National Formulary, but an impractical one containing confect. democratis, bolet. laricis, etc. In spite of such criticisms, however, we believe the work to be the best of its kind; and it would be welcomed by the medical student were it not that a lavish waste of space in the printing makes the volume too cumbersome for the pocket, and, in proportion to its contents, too expensive.

MATIÈRE MÉDICALE ZOOLOGIQUE. Histoire des drogues d'origine animale. Par H. BEAUREGARD, Professeur à l'Ecole Supérieure de Pharmacie de Paris. C. Naud: Paris.

IT IS an interesting comment on the reversal of the order of things to find this work of 400 pages devoted exclusively to the study of animal products and their therapeutic uses.

In the works on medicine of the Middle Ages much space was devoted to animal products, but their number has slowly diminished and up to comparatively recent times a bare half-dozen sufficed. For the past decade more and more attention has been devoted to animal products and this excellent volume is an outward visible sign of this interest.

It is the most complete work on the subject with which we have come in contact and it is very largely a work embodying much actual research, other than the usual industry of the compiler of monographs from literary sources. In the chapters on the odoriferous principles of musk, ambergris, etc., there are to be found a large number of new facts, also in the chapters on the irritative secretions of insects. This work is to be most heartily recommended.

A TEXT-BOOK OF DISEASES OF WOMEN. By CHARLES B. PENROSE, M.D., Ph.D., formerly Professor of Gynecology in the University of Pennsylvania; Surgeon to the Gynecean Hospital, Philadelphia. Fourth Edition, Revised. W. B. Saunders & Company: Philadelphia and London.

IT IS definitely stated that the author intends this work to be a text-book for students and the various theories and causations of gynecological disturbance are therefore to be simply and lucidly stated. That there may be no confusion as to the proper operation for the various conditions met with, but one operation is described in each case or condition. We doubt the wisdom of this as the object of any text-book is to give the student a bird's-eye view of what can be done and, at the same time, at least make him familiar with the names or general outline of several different operative procedures in any given condition.

In Chapter XI. the text is at variance with the majority of authorities with reference to the histological contents of the bands or ligaments formed in uterine suspension after the uterus has been sutured to the abdominal wall. Kelly and the larger majority of writers hold that these bands are composed of the drawn-out fibrinous exudate from the peritoneum, while the author says they contain muscle fibers and peritoneum.

The chapter devoted to the diseases of the bladder and its appendages is decidedly meager and incomplete. Cystitis is spoken of in a general sort of way and the various etiological factors (bacteria, etc.) in its causation are entirely ignored. There is little or no mention made of the kidney in its pathological conditions.

In local and systemic treatment the author gives most excellent methods which are specific and at the same time conservative. This should be of great help to students who usually find text-book treatment too vague for their comprehensions.

The illustrations, which are by Margueretta Washington and others, are exceedingly clear as well as artistic. The many minor changes in the text have added greatly to the value of the publication.

A TEXT-BOOK OF MEDICINE. For Students and Practitioners. By Dr. ADOLF STRÜMPELL, Professor and Director of the Medical Clinic at the University of Erlangen. Third American Edition. Translated by HERMAN F. VICKERY, M.D., Instructor in Clinical Medicine, Harvard University, and PHILIP COOMBS KNAPP, M.D., Clinical Instructor in Diseases of the Nervous system, Harvard University; with Editorial Notes by FREDERICK C. SHATTUCK, M.D., Jackson Professor of Clinical Medicine, Harvard University. D. Appleton and Company, New York.

PROF. STRÜMPELL'S text-book is too well known to need special commendation here. It is encouraging to note that the appreciation for the work grows as time goes on. The author announces that, thus far, translations of his text-book have appeared in the following languages: French, English, Italian, Spanish, Russian, Modern Greek, Turkish and Japanese. Some of these translations, he adds, have had several editions. The present volume represents the third American edition from the thirteenth edition in German.

Professor Strümpell confesses that the task of perfecting his work grows more difficult with every new edition, as scientific workers are making deep and extensive investigations into the many subdivisions of internal medicine with such zeal and skill that it becomes difficult for any one man to keep step with the unceasing progress of investigation in this wide domain and to maintain that complete and universal command of facts and theories which is essential for a presentation of the subject which shall be at once brief and true to the present standpoint of science. There is no doubt that Professor Strümpell has accomplished this self-appointed task about as nearly perfectly as is possible under the circumstances.

The American edition has the advantage of additions by the American translators and by the editor. These usually refer to certain recent advances, as, for instance, to the prophylaxis of the transmission of malaria by the avoidance of mosquito-bites, the status of the Widal reaction and other recent medical work.

The thoroughly practical character of Professor Strümpell's book is the reason for its popularity. The notes on treatment are especially full and eminently suggestive. A typical example is the following passage taken at random from the treatment of cough in tuberculosis: "We try inhalations with a solution of common salt or of the alkaline carbonate, or, if there is much secretion, with solutions of tannin and the balsams, such as turpentine or balsam of Peru. When there is severe spasmodic cough, inhalations with narcotic solutions give some relief, such as cherry laurel water, opium, or bromide of potassium. It is important that the patient should learn to suppress his cough at least up to a certain point. Sips of cold water often quiet the cough, as may also a cough-drop held in the mouth, or a pastille containing the salt found in Ems mineral water."

BOOKS RECEIVED.

The MEDICAL NEWS *acknowledges the receipt of the following new publications. Reviews of those possessing special interest for the readers of the* MEDICAL NEWS *will shortly appear.*

AN AMERICAN TEXT-BOOK OF PATHOLOGY. Edited by Drs. Ludvig Hektoen and David Riesman. 8vo, 1245 pages. Illustrated. W. B. Saunders & Co., Philadelphia and London.

STUDIES ON THE INTERNAL ANATOMY OF THE FACE. By Dr. M. H. Cryer. 8vo, 176 pages. Illustrated. S. S. White Dental Mfg. Co., Philadelphia.

LAMARK, THE FOUNDER OF EVOLUTION. By Dr. A. S. Packard. 8vo, 450 pages. Illustrated. Longmans, Green & Co., New York, London and Bombay.

SPECIAL ARTICLES.

REPORT OF THE COMMITTEE OF SEVEN ON THE PROPHYLAXIS OF VENEREAL DISEASE IN NEW YORK CITY.

BY THE CHAIRMAN.

THE Committee of Seven appointed by the President of the Medical Society of the County of New York for the "Study of Measures for the Prophylaxis of Venereal Diseases," in pursuance of a resolution adopted by the Society February 25, 1901, begs leave to submit the following report.

The Committee organized April 4th by the election of Dr. Prince A. Morrow, as Chairman, and Dr. L. Weiss, Secretary. A number of meetings have been held.

As the study of measures for reducing the morbidity and mortality from venereal diseases was the object of the Committee's creation, it was thought that some definite knowledge of the magnitude and extent of the evil and the nature and causes of the conditions concerned in its spread would form the best groundwork for an intelligent study of the remedial measures to be recommended.

At the outset the Committee was confronted by the fact that there were no statistics regarding the prevalence of venereal diseases in this city. The existence of this class of diseases has always been ignored by the sanitary authorities and the amount of venereal morbidity was purely conjectural. In outlining the plan and scope of the Committee's work it was decided that an investigation should be made of the prevalence of venereal diseases in both private and public practice in this city.

With this view the following circular letter was drafted and a copy sent to each of the 4,750 physicians resident in Greater New York.

NEW YORK, May 1st, 1901.

DEAR DOCTOR:

The Committee appointed by the Medical Society of the County of New York for the Study of Measures for the Prophylaxis of Venereal Diseases deems it important to ascertain the amount of venereal morbidity in this city.

As a large number of the cases of venereal disease occurring in our civil population are treated by physicians in private practice, the Committee would ask the coöperation of the entire medical profession in securing statistics bearing upon this subject.

As this information is sought for solely in the interest of the public health, and does not in any way violate professional secrecy, the Committee trusts that you will answer promptly the appended series of questions and forward to the Secretary.

I. The number of cases of venereal disease occurring in your private practice during the past year.

1. Number of cases of Gonorrhea, ...
2. Number of cases of Syphilis, ...

It is also desirable to obtain, where practicable, detailed statistics as to:

3. Cases of Gonorrhea occurring in
   - a. Men, ...
   - b. Women, with pelvic complications, ...
   - c. Children, Ophthalmia, ...
   - c. Children, Vulvo-vaginitis, ...

   Total, ...

4. Cases of Syphilis occurring in . .
   - a. Men, ...
   - b. Women, ...
   - c. Children, Acquired, ...
   - c. Children, Hereditary, ...

   Total, ...

5. Also as to the origin of the Infection — whether from . . . . .
   - a. Public prostitutes, ...
   - b. Clandestine prostitutes, ...
   - c. Marital infection, ...
   - d. Hereditary infection, ...
   - e. Extragenital infection, ...
   - f. Unknown source, ...

   Total, ...

The Committee is desirous of gaining the fullest possible information relative to the prevalence of *syphilis insontium,* of gonococcic infection in married life, and of venereal diseases occurring in children.

II. Judging from the results of your observation, are venereal diseases on the increase in this city?

III. What measures, in your opinion, are best adapted to limit or prevent the dissemination of venereal diseases in this city?

A circular letter was also handed to the superintendents of various dispensaries and public institutions in New York City in which this class of cases is received by the representative of the Committee, asking permission to inspect their records.

To the circular letter sent to the members of the medical profession relating to the statistics of private practice 886 replies were received—nearly 20 per cent. While it was hoped that the response would be more general, this proportion was not a distinct disappointment, as the Committee was fully aware that, in all attempts to gather mass statistics concerning any disease or class of diseases, a large proportion of physicians to whom such inquiries are addressed fail to reply, either from indifference to the particular subject of inquiry, from indisposition to take the trouble to make the necessary tabulation of statistics or from lack of interest or sympathy with the objects of the investigation.

Of the 886 replies, a few were flippant in tone, but the remainder were serious, well considered, and evidently prompted by a recognition of the importance of the Committee's work and in a spirit of cordial coöperation.

Two hundred and eight of the 886 replies contained no statistics, some on the ground that the writers kept no records of their cases, others that it would involve too much trouble to go over their books for an entire year. Many of the eye, ear and throat specialists, gynecologists, neurologists,

etc., admitted that they treated a large number of venereal cases, but it was usually for complications, or late manifestations which were recorded under other titles, and that it would require too much work to identify and classify them.

It is but proper to say that most of these gentlemen, although declining to send their statistics, manifested sufficient interest in the objects of the Committee's inquiry to give their views in answer to Question III., as to the best measures to prevent the dissemination of venereal diseases in this city.

The statistics of some of the reporters were excluded on account of their indefiniteness—thus a number stated that they treated, roughly speaking, from 50 to 100, or, as in one reply, from 200 to 300 cases of venereal diseases the past year—none of these was included.

It will thus be seen that 678 physicians, *or about one in seven* of those to whom the circular was addressed, forwarded statistics of venereal disease occurring in private practice. The total number of cases reported by these 678 physicians, which are duly tabulated and preserved in a permanent form for reference, is 23,196—15,969 cases of gonorrhea and 7,200 cases of syphilis. It is to be understood that no cases of chancroid are included. While the frequency of chancroid is variable, being less in private than in public practice, the statistics of all authors in all countries estimate it from 9 to 35 per cent. of the total of venereal morbidity. Neither do these figures include the large number of the sequelæ of gonorrhea, pelvic complications excepted—strictures, etc., and a vast deal of morbidity which is distinctly and directly of venereal origin.

Taking this aggregate of 23,196 cases reported by 678 physicians, it would seem fair to assume that an equally large proportion of cases occurred in the practice of those who sent no report, and upon this basis of calculation there would be a total of 162,372 cases of gonorrhea and syphilis treated during the past year in private practice in this city.

Now it may be claimed, and with perfect propriety, that as many patients go from one physician to another, they may figure more than once in the statistics, but, abstraction made of these cases, the Committee believes that the aggregate of venereal morbidity in private practice in this city is much below rather than above the total here indicated. When we take into account the large number of venereals who are treated by advertising empirics, by druggists, and by secret nostrums, and the very large contingent who are not treated at all or use prescriptions given them by friends, the above figures would be easily swollen much beyond this aggregate.

The testimony of many European physicians is that from 25 to 50 per cent. of all venereal cases are treated by charlatans. In this country it is not possible to make an accurate estimate, but it is evident that the number is large. The advertising quacks in this city could not keep up expensive offices, put costly advertisements in the daily papers, print and distribute their private literature unless they derived a large revenue from this source. Again, the business of certain drug-stores is another evidence of the extent of this irregular practice. In addition to the secret nostrums, the "sure cures," the "blood purifiers" which are found upon their shelves, many druggists cauterize sores and put up injections, pills, etc., without the advice or authorization of a physician. It is not intended to assert that all druggists engage in this business, but it is well known that many of the smaller drug-stores in various parts of the city owe their chief source of revenue to this class of practice.

Upon analyzing these statistics farther it is found that under gonorrhea are grouped 12,956 men and 1,941 women. This preponderance of males, which might be misleading, is explained by the fact that many reporters gave in their returns so many cases of gonorrhea, so many cases of syphilis, without indicating the sex of the individual. In tabulating the statistics all such cases were placed in the tabular column of gonorrhea in men.

Among the 1,941 cases of gonorrhea in women there are 724 with pelvic complications—nearly 40 per cent.

Among children there are 265 with purulent ophthalmia; 218 with vulvo-vaginitis; 5 with urethritis.

In the group of syphilis there are 1,657 cases of syphilis in women, 61 children with acquired syphilis (evidently due to contagion in family life), and 468 children with hereditary syphilis. This latter number is all the more significant when it is remembered that from 80 to 86 per cent. of all syphilitic pregnancies terminate fatally, for each surviving child would represent 5 deaths from syphilis.

As to the origin of the infections, 8,053 were attributed to public and 3,915 to clandestine prostitutes. In explanation of this marked discrepancy as compared with foreign statistics, it may be said that the line of distinction between the two classes is not sharply drawn in this country. Abroad only those subjected to registration, and therefore licensed, are termed public prostitutes; all the others are classed as clandestine

There are reported 988 cases of marital infection (presumably, as is the rule, from husband to wife). The returns do not indicate whether these marital infections are of syphilis alone, or embrace both syphilis and gonorrhea. If the former, they would show that of 1,657 syphilitic women, nearly 60 per cent. have received syphilis from their husbands. If they refer to both (gonorrhea and syphilis), they would indicate that nearly 30 per cent. of all venereal infections occurring in women in private practice in this city are communicated by the husbands. It is but proper to say that, if the Committee's basis of calculation is regarded as legitimate, all the figures just given should be multiplied by seven, in order to express their full significance.

There are many other interesting deductions

from these statistics which must be passed over from lack of space.

Of the 45 dispensaries and charitable institutions in Manhattan visited by the representatives of the Committee 9 declined permission to inspect their records, or refused to give the information sought for on the ground that they did not receive venereal cases. Of the 37 in which permission was given to inspect the books, or the desired information was furnished by the superintendent or house surgeon, there were collected records of 14,649 cases of gonorrhea and 7,607 cases of syphilis, a total of 22,256 treated during the year.

There were 9,452 cases which were grouped under venereal diseases, but in which the records did not indicate a distinction between gonorrhea and syphilis, swelling the list to 31,708. In addition there were found upon the records of the dispensaries 3,907 cases of chancroid, 898 cases of epididymitis and orchitis, 332 cases of cystitis, 414 cases of bubo, 261 cases of venereal warts, 172 cases of balanitis and phimosis, 523 cases of ophthalmia, 142 of ophthalmia neonatorum, 19 of vulvovaginitis in children, 195 of hereditary syphilis; 30 of the cases were caused by extragenital infection. This by no means represents the amount of venereal disease treated in our public institutions. Although gonorrhea and syphilis are ostensibly not treated in the general hospitals of this city, we find records of cases in the few investigated—many thousands altogether—in which the sequelæ of gonorrhea and the late systemic manifestations of syphilis are received and treated, but entered under names which are not recognized by the laity as indicating a venereal origin. Thus in one of the eye hospitals there were 136 cases classed as purulent ophthalmia, in all of which the gonococcus had been identified by bacteriological examination as the pathogenetic factor. In the same institution there were 38 cases of interstitial keratitis, indubitably of syphilitic origin, but not indicated in the record. It would seem that, in the society of diseases, venereal diseases represent the criminal classes—they are disreputable—they have a bad character and, like most criminals, when they consort with the respectable element they masquerade under an alias, so that in a public hospital it has been ordained that they appear not under their true names, but disguised under a variety of aliases which do not betray their venereal origin.

The annual reports of a few of our general hospital record 371 cases of salpingitis, 1,762 of endometritis, 335 of pyosalpinx, 45 of salpingo-ovaritis, 48 of vulvovaginal abscess, 169 of vaginitis, 651 of stricture, 173 of gonorrheal rheumatism. Altogether there were collected records of 9,731 cases, including many cases in the hospitals under titles indicating their venereal origin, making a total of 41,439. The records of the hospitals also abound with cases of locomotor ataxia, rickets, cerebral and spinal accidents, monoplegias, hemiplegias, general paralysis, epilepsy and various nervous affections in which syphilis is a common etiological factor.

It would seem a strange perversion of the proper purposes of charitable institutions that a patient is debarred entrance into our general hospitals when the disease is acute and a source of danger to others, but he is readily admitted when suffering from the remote effects of the disease which might have been prevented by prompt treatment.

Practically the hospitals proclaim to this class of patients, "We cannot receive you when your disease is acute and curable, but when your gonorrhea has developed into stricture, salpingitis, peritonitis, or when your syphilis has affected important central organs, the brain, the spine, the organs of special sense, you may be received, but your disease shall be baptized under another name which does not offend the refined susceptibilities of our patrons."

The Committee must censure the attitude of the governing boards of our hospitals in excluding all mention of venereal diseases from their reports, as if it were a shame and a reproach. While it may be true that a respectable syphilis does not exist, they give the public the impression that it is almost as disgraceful to treat syphilis as to contract it.

It is to be regretted that these statistics could not have been more definite—giving in all cases the age, the stage of the disease or other important particulars, but the imperfect methods of recording cases in many institutions render this impossible.

While it is no part of the Committee's province to discuss the system or rather lack of system in keeping records which was disclosed by an examination of the books of many of our public institutions, yet we feel that in the interest of scientific research a uniform nomenclature of venereal diseases should be adopted and a more orderly method should be introduced in keeping records.

The most obvious defects noted were, in the first place, an omission of the diagnosis, in some institutions amounting to 20 to 100 per cent. and the lack of uniformity in the terms used to designate the diseases—a veritable nosological anarchy. Thus, syphilis was variously designated as chancre, primary lesion, initial lesion, hard sore, X., XX., and XXX., (S.), lues, s. pox, "specific," spec., sp.; gonorrhea as clap, sp. gon., with nipper, blenorrhagia, drop, etc. In some records there were private marks to designate the disease known only to the physician in charge. All indications as to the stage of the disease, of syphilis, whether secondary or tertiary; of gonorrhea, whether acute or chronic, the number of the attacks, complications and other important particulars were absent. The adoption of a uniform nomenclature of venereal diseases should be urged upon the officers of all public institutions in which these cases are treated.

It is hoped that the very defects which the statistics in this report discloses—defects which are

inseparable from the confusing nomenclature employed and the imperfect methods of keeping records—will lead to a reform in this matter.

Much credit is due the representative of this Committee, Dr. A. D. Mewborn, for the painstaking care with which the records of the public institutions were investigated and the thoroughly conscientious manner in which he endeavored to arrive at accurate results. That there was no disposition to swell the total it may be observed that, while the official records of the Bellevue Out-Patient Department showed 7,300 cases of venereal diseases treated in the Genito-Urinary Department, only 5,872 appear in this record. The Vanderbilt Clinic records 2,938 cases of venereal diseases treated in the venereal clinic, but only 2,263 are included in this report. Instances in which the diagnosis was wanting, as was not infrequently the case, were not included in this report.

It will be observed that these statistics were confined to certain institutions in the borough of Manhattan. None of the island institutions, the Penitentiary, Workhouse, Almshouse, House of Refuge, and many of the public hospitals were not visited. The institutions in Brooklyn and other boroughs were not investigated.

The only available basis for a comparative estimate of venereal morbidity in the other boroughs appeared to be the mortality statistics of all the public institutions of Greater New York. The deaths for 1899 in the public institutions of the borough of Manhattan were 10,157. The deaths in the institutions of all the other boroughs were 5,400, a little over one-half. Applying this basis of calculation, the total number of cases of venereal diseases treated in the institutions in Greater New York would foot up to a total of 62,157 cases; this, with the cases treated in private practice, would make a grand total of about 225,000 in both private and public practice.

This total the Committee regards as rather under than above the actuality. The figures do not, of course, represent the sum total of venereal morbidity, but only the number of cases actually treated during the year. There is no class of diseases so serious in their direct and ultimate effects upon the health of the individual, which are so apt to remain untreated. One cause is the ignorance of their significance on the part of patients, another is the feeling of shame and fear of detection on account of the publicity inseparable from the conditions under which dispensary treatment is given.

This estimate of the fruits of prostitution in New York City takes no cognizance of its incidence among the strangers within our gates. Among the million or more of the floating population of this city—strangers who come for business or pleasure—it is well known that many are worshipers at the shrine of Venus and carry with them to their homes sad souvenirs of their sojourn in the metropolis. In this rich harvest field of infection they often reap more than they sow.[1]

[1] These figures do not include statistics of venereal diseases among sailors in this city, some of whom bring the infection from foreign ports, but many more contract the disease in the dives and dance houses frequented by sailors along the water-front and in the lower parts of this city. The attending physician of the Merchants' Marine Hospital Service and Dispensary states that no fewer than 18,000 cases of gonorrhea and syphilis were inspected and treated during the past year among the crews of the steamships carrying no passengers. He states further, "If we add to this cases occurring on board passenger ships and sailing vessels, the total will be from 25,000 to 30,000 annually."

Whatever may be the sum total of venereal morbidity in this city, enough statistical evidence has been adduced to show that there exists in our midst a vast amount of contagious disease which constitutes a grave danger to the public health and which is absolutely ignored by our sanitary authorities. *Officially,* venereal diseases do not exist in New York City.

Mortality of Venereal Diseases.

Let us compare for a moment this sum of morbidity with that of the contagious diseases which do come under the official cognizance of the Board of Health. To take the past year, 1900, when the morbidity of contagious diseases was unusually heavy, the records show that of measles there were 12,530 cases, 816 deaths; diphtheria, 11,001 cases, 1,920 deaths; scarlet fever, 7,387 cases, 465 deaths; chicken-pox, 1,251 cases, 1 death; smallpox, 99 cases, 12 deaths; tuberculosis, 8,877 cases, 8,154 deaths.

The above figures may be accepted as an approximately accurate census of contagious disease, with the exception, perhaps, of tuberculosis. Against these we have a venereal morbidity of 225,000 cases.

Now, as regards the mortality from venereal diseases, a matter which properly comes within the scope of the Committee's inquiry, the vital statistics record 177 deaths from syphilis. The Board of Health officials readily admit that this number affords no correct indication of the mortality from this disease. From a regard for the feelings of relatives and an indisposition to brand the patient's memory with the stigma of a compromising disease, deaths from syphilis are concealed under various causes—in the adult scrofula, compression of the brain, and other innocent titles; in children, marasmus, infantile debility, convulsions, etc., in but a fraction of the cases is the real disease mentioned. But if we consult the mortuary records we shall find that syphilis is buried under a variety of names. In many of the 1,179 cases of premature birth, in 2,136 deaths recorded as due to marasmus, and in the 28 deaths from hydrocephalus, etc., syphilis was doubtless a casual factor. In many of the 5,590 deaths from diseases of the nervous system, such as 50 deaths from locomotor ataxia, 341 from general paresis, 875 from softening of the brain, 232 from hemiplegia, 96 from paraplegia, 83 from aneurism and diseases of other important organs, syphilis doubtless entered as an etiological factor. The records of the Randall's Island Nursery Hospital show that 8 per cent. of the total deaths from all causes in the institution are due to hereditary syphilis.

Gonorrhea is not mentioned as a cause of death, but we find in the group of "urinary diseases"

and in diseases of the "organs of generation" a large number of deaths in some of which gonorrhea might well be considered as the remote cause; thus there are recorded 141 deaths from ovarian disease, 137 from diseases of the uterus and vagina, and 27 from pelvic abscess.

While the mortality bill of venereal diseases is indefinite, it is doubtless much larger than is generally supposed.

We may well ask why certain infectious diseases are elevated to the dignity of a danger to the public health and every effort made to prevent their spread, while another class of diseases, compared with which the morbidity of the former is but a molehill to a mountain, is completely ignored. To take for example smallpox, of which in the year 1899 there were 18 cases and 11 deaths, and in 1900 99 cases and 12 deaths. All the energies of the Health Department, with an expensive equipment, a large corps of public vaccinators were employed in preventing its spread—while the great pox was allowed to feed and batten upon the community unchecked and unnoticed.

To Question II. in the circular letter issued by the Committee, "Judging from the results of your observation, are venereal diseases on the increase in this city?" there were 412 replies, 212 affirmative and 200 negative. It is, of course, impossible to answer this question intelligently or definitely, because there are no statistics of the prevalence of these diseases in this city at different epochs to serve as a basis of comparison. The value of the work which this Committee has attempted to inaugurate can be no better illustrated than by the unfortunate absence of such data. Dr. Gross, in his paper on "Syphilis in Its Relation to the Public Health," declares that it would be a matter of deep interest and of the greatest possible value if we could ascertain even approximately the extent of syphilis in our cities and larger towns.

In his history of prostitution, Sanger estimated that there were 9,487 cases of venereal diseases treated in the island institutions, public hospitals and dispensaries of New York and Brooklyn and the "Seaman's Retreat" on Staten Island in the year 1857. His basis of calculation was that there were 3 per cent. of venereal patients treated in the dispensaries and 10 per cent. in the hospitals. These 9,487 cases, he thought, represented only two-thirds of the aggregate, which he places at 14,770. He found that the statistics of the Penitentiary Hospital (now the City Hospital), Almshouse, Workhouse and Penitentiary, showed that of the total number admitted to these several institutions 59½ per cent. were suffering from venereal disease at the time the inquiry was made. The Penitentiary Hospital, he states, was the only public hospital where venereal disease is confessedly treated. It may be interesting to learn that at that period, while "Bellevue Hospital is not professedly available to venereal cases, yet the Medical Board of that institution estimates that not far from 10 per cent. of the inmates are admitted for affections which have their origin remotely in venereal disease."

Basing his estimate upon the assumption that the number of cases of venereal disease treated in private practice quadruples the number treated in public institutions, Sanger concluded that in the year 1857 there were 74,000 cases treated in New York. At that time the population of the city was about 700,000. In 1874 Dr. Sturgis estimated "that out of a population of 942,292, 50,450 were suffering from syphilis in New York City." In an appendix to Dr. Sanger's book, 1892, it was estimated that 100,000 persons out of a population of 1,800,000 had syphilis. The population of Greater New York at the present time is about 3,560,000; assuming that the rate of increase of venereal disease has kept pace with the growth of the population, there would be on this basis of calculation nearly 200,000 syphilitics in this city. All of these estimates are, of course, purely conjectural, without any statistical basis.

PROPHYLACTIC MEASURES.

Regulation.

To Question III., "What measures in your opinion are best adapted to limit or prevent the dissemination of venereal diseases in this city," there were 1,065 recommendations, some advocating more than one measure. The onerous duty of analyzing this mass of material devolved upon the Secretary, Dr. Weiss, and the thanks of the Committee are due him for his work in classifying these answers for tabulation under appropriate headings.

As the Committee has asked for an expression of views upon this most important question, it is proper and fitting that these recommendations should be duly considered.

Three hundred and forty of these may be grouped together as advocating the same radical measure—regulation.

In discussing the value of remedial measures for the prophylaxis of venereal diseases it would not be the part of wisdom to confine ourselves to the meager statistics collected by this investigation which do not bear directly upon the subject. We should take a broader and more general survey of the question and utilize the results of the experience and observation of foreign students upon the practical workings of this system in countries where it has been tried, as a basis for conclusions.

The system of regulation in France serves as the type of that employed in other countries and its main features may be thus briefly summarized. It represents an association or combination of effort on the part of the administration authorities and the medical profession with a view to render the practice of prostitution less dangerous to the public health by the elimination of sources of contagion in women who are engaged in it. A special corps of police is employed, every woman in the streets suspected of prostitution is arrested, her name is inscribed on

a special register and she is given a card which is an authorization to exercise her trade under certain conditions; the most important obligation is to report at stated intervals for medical examination. When found diseased she is sent to a special hospital and detained until her contagious accidents are cured. This system, it will be seen, rests upon the tripod of police force, medical examination and hospital isolation—the hygienic feature is the medical examination.

The success of the system depends upon two factors, the activity and vigilance of the police in bringing women under supervision and the thoroughness of the examination in detecting sources of disease.

As regulation has been employed in France for over half a century, and in other European countries for a longer or shorter period, there has been ample opportunity to test its value in reducing venereal morbidity.

Without presenting an analysis of the mass of statistical evidence accumulated, a calm and impartial study of the practical results of regulation would seem to demonstrate that it does prevent a certain amount of infection in men. The much smaller proportion of infections which can be traced to regulated prostitutes, and the much larger percentage of venereal disease in women not regulated, are evidences of its value.

It requires no prejudice in its favor to concede that the detection and enforced isolation of so many sources of infection must have a material influence in limiting the dissemination of venereal disease. For example, the statistics of Commenge show that of the 15,095 syphilitic women sent to the St. Lazare Hospital during a period of twenty years, the average detention was thirty days, which gives a total of 452,850 days in which they were prevented from all possibility of transmitting their disease.

Further consideration of this system might be dismissed on the ground that whatever may be its value public opinion forbids its introduction in this country. Sentimental objections should not, however, be allowed too much weight in the discussion of purely sanitary schemes. It is the high mission of the medical profession to educate and direct public opinion in all sanitary matters. As to the practical objection that the organization of our public hospitals is such that one most essential condition of this sanitary scheme is wanting, viz., sufficient provision for the isolation of a large number of venereal cases, it may be said that increased hospital facilities could doubtless be obtained. But there are other and more weighty objections to regulation which may be briefly referred to. The fatal defect of this system is to consider public or professional prostitutes the almost exclusive sources of contagion, when as a matter of fact they constitute only a small minority. It is and always will be defective and incomplete in its operation because only a small proportion of prostitutes can be subjected to its provisions. There is an invincible repugnance on the part of women to be labeled with a number, compelled to be inspected as articles of merchandise and forcibly detained in a hospital. Not 10 per cent. of the public prostitutes can by any police intervention be collected, and of these about one-fifth annually disappear from observation and become clandestine prostitutes. Regulation cannot be effectively applied against the large body of private or clandestine prostitutes, it cannot reach the great mass of masculine spreaders of contagion.

Another defect is that the medical examinations conducted once a week or ten days are insufficient to promptly detect sources of contagion. New infections of the women may be manifest the day after the weekly examination has been completed and in the intervals between visits every comer may be contaminated.

Again the bacteriological examinations demanded by modern science as a test of the existence of gonorrheal disease cannot possibly be made with thoroughness when a large number of women are to be examined within a short time. All specialists recognize the difficulty of detecting the initial lesion in women or of pronouncing positively upon the syphilitic character of certain accidents. Another defect is that the shortness of stay in the hospital, which does not average more than 30 days, is notoriously insufficient especially in disease of prolonged contagious activity and with such frequent recurrences as syphilis. For these and other reasons the Committee does not recommend the Continental system of regulation as a remedial measure; while it has the incontestable advantage of hygienizing a limited number of public women, the evidence is by no means clear and conclusive that it materially diminishes the sum total of venereal diseases in countries where it has been most perfected and employed It has so many countervailing disadvantages, it is vulnerable from so many points of view that the movement for its modification or abolition in many European countries will probably result successfully.

The Committee is fully impressed with the conviction that private prostitution represents the most dangerous phase of the evil both from a sanitary and moral point of view, and that one test of the value of a remedial measure is its influence in disseminating the evil and recruiting the ranks of clandestine prostitutes.

Segregation.

A further analysis of the replies shows that 203 recommend the segregation of prostitutes. In a medical sense segregation means the enforced separation of certain individuals from their fellows and their collection in one locality in a more or less isolated group.

The Committee does not deem it wise at the present time to advise segregation of prostitutes in one specified quarter of the city, with the understanding that in this locality they may be permitted to exercise their vocation without molestation. Public sentiment is extremely sensi-

tive to anything like legal recognition or sanction of this evil, and it is impossible to approach the boundaries of toleration without entering the confines of authorization.

This question possesses a peculiar pertinence at the present time. As an outcome of the work of the Tenement-House Commission, the elimination of prostitutes from the tenements and apartment houses of this city may be accepted as a foregone conclusion. The vigorous enforcement of this law will doubtless result in casting out many hundreds of public women; the question is, what shall be done with the outcasts? While the Committee does not feel charged with the responsibility of suggesting a provision for this class of evil-doers, yet since they are chiefly concerned in the propagation of venereal diseases, their disposition has some bearing upon the objects of this inquiry. From a common sense as well as a humanitarian point of view, it is evident that these unfortunates must be permitted a habitation. They cannot be forced into the river and drowned as 800 of them were at one time under the edict of a French emperor. They cannot be driven forth into the hills and fields, denied food and shelter and left to perish as was done at a later period at Edinburgh. The brutal methods carried out with savage energy which characterized former crusades against these unfortunates are opposed to the spirit of the age in which we live—certainly they find no place in the counsels of enlightened sanitary science. What shall be done with the outcasts is a most perplexing problem, as it touches at many points questions of morality, of law and order as well as personal rights. It will be admitted that in principle prostitution is wrong and that its entire suppression would be the ideal condition; but this ideal is unrealizable. Prostitution is inherent in the human race; it cannot be annihilated, it is a necessary evil in our social system. We are confronted with the fact that the prostitutes, like the poor, we shall always have with us. In dealing with this evil, speculative arguments, based upon an abstract principle which involves the perfectibility of the human race, should yield to the doctrine of expediency. The most feasible plan appears to be to compel all prostitutes to inhabit houses by themselves. Immoral women should not be allowed to dwell in the same house with moral families. This domiciliary separation should be absolute and complete. To accomplish this result no new legislation relating to prostitution *per se* is necessary, but rather a relaxation of the law applying to the existence of disorderly houses. By simply abandoning this evil to its own evolutionary mode, which is always toward aggregation, unless scattered by the force of repressive measures, it would naturally drift into certain streets or quarters following, of course, the line of least resistance on the part of property-owners. Prostitutes are essentially gregarious and the natural history of prostitution shows that, like other trades, it has a tendency to aggregation, obeying the same commercial law which determines the localization of certain lines of business in certain districts or quarters. The colonization of certain nationalities in distinct quarters, such as the Chinese, the negro quarters, etc., is another evidence of this tendency to aggregation. The Committee is fully persuaded that the interest of public health, as well as of public morals and public decency, can be best subserved by the localization of this evil in certain streets or retired quarters of the city where it will not obtrude itself upon observation, where it must be sought for to be found and where it can most effectively be brought under control. The existing regulations which apply to solicitation in the streets, provocation to debauch through open windows or indecent exposure, and all offenses against public order and decency should be strictly enforced. All red light or other indications of the nature of such houses and all external and visible signs of prostitution should be rigorously prohibited. This arrangement would take out of the hands of the police the arbitrary power of levying tribute, which has proven so demoralizing to the force. The function of the police would be limited to the preservation of order and the repression of all scandalous behavior in the streets.

Regulation by the Board of Health.

Among measures suggested, regulation by the Board of Health is recommended by 152 physicians, report of cases to health department by 15, and isolation by quite a number of others.

It will be admitted that the control of venereal disease, as of other contagious diseases, naturally and legitimately comes within the province of our sanitary authorities who are the accredited representatives of the State in all matters relating to the protection of the public health. Now, venereal diseases, like other contagious diseases, are already subject to the control of the Board of Health; this Board, however, does not officially recognize the existence of these diseases or employ any sanitary measures for their control. The first essential is to awaken the health authorities to a sense of their responsibility.

Sanitary control is not necessarily limited to the measures employed in the case of acute infectious diseases, *viz.*, compulsory notification and enforced isolation during the entire contagious period. These routine methods by no means represent the sole resources of sanitary science. Isolation contemplates brevity, and in dealing with chronic infectious diseases like syphilis or tuberculosis would be impracticable. The ordinary methods of sanitary procedure should be adapted to the peculiarities of the particular disease, its nature, its mode of contagion, and the conditions under which it is spread.

When the health authorities proposed to bring tuberculosis within the sphere of sanitary supervision it was certainly not with the view of isolating the great army of consumptives; the spread of tuberculosis has been combated by other means. A campaign of education was instituted,

the public was taught that it was a communicable disease, instructed as to the agencies by which it is propagated in family life, of the risk consumption carries to others and the best means of avoiding these risks. A bacteriological laboratory was created to examine the sputum in suspected cases, so that the disease might be detected in its earliest stage when it was amenable to cure. Increased facilities for its treatment were also provided. The work done by the Health Board of New York in their efforts to stamp out the seeds of consumption met with the most appreciative recognition at the last meeting of the Tuberculosis Congress in London.

The Health Department of this city is armed with full authority to enforce all measures which in its judgment are deemed essential to the preservation of the health of the community. The public is willing to submit to measures, if ordered by the Board of Health, which might be considered an infringement upon private and individual rights, while it would resent the imposition of similar restrictive measures by social reformers or others. There may be a difference of opinion as to the moral aspects of the social evil and the propriety of restrictive measures in so far as it constitutes an offence against morality, but there can be no strenuous opposition to a sanitary movement which has for its sole object the repression of disease.

This Committee is not prepared to formulate a system of control complete in all its details and embodying the methods to be employed in combating the spread of venereal disease. It will be conceded that the problem is most difficult, but its solution should be undertaken and the difficulties met as they arise. While it is obvious that placing venereal disease under the ban of notifiable diseases would not be judicious or practicable, there could be no objection, however, to the registration of all cases of venereal disease, the physician reporting the nature of the disease, the origin of the infection whenever practicable, without giving the name and address of the patient, and thus respecting professional secrecy. All public institutions, hospitals and dispensaries should be required to report all cases of disease of venereal origin. The establishment of a distinct bureau under the Division of Contagious Diseases, with a special corps of sanitary inspectors, chosen for proficiency in the knowledge of this class of diseases, with a bacteriological laboratory for the examination of diseased secretions, and other administrative details, would be matters for further consideration.

The keepers of disorderly houses should be required to report all cases of disease occurring among the inmates of their establishment under penalty of a heavy fine, and such diseased women should be retired from circulation until their contagious accidents are cured. To meet this exigency there should be increased hospital facilities for the reception and treatment of venereal diseases.

From a hygienic standpoint prostitution should be loked upon as a sanitary sin and supervised like any other trade which menaces the public health by the disease it engenders.

Penalizing the Transmission of Syphilis.

The question of penalizing the transmission of syphilis, as recommended in many of the replies, is viewed differently by members of the Committee. The difficulty of positively identifying the origin of the infection in a disease of such prolonged incubation as syphilis, the impossibility of determining the source of the disease when promiscuous intercourse has been indulged in are complicating elements, yet there are many cases in which the penalty could be enforced without a miscarriage of justice. If such a law is deemed advisable it should be drafted by those skilled in the framing of legislative enactments with due regard to the nature of the disease and eliminating all possibilities of blackmail. It may be said that if public sentiment sustains the Board of Health in imposing a heavy fine for spitting on the floor of cars and public conveyances, with the remote possibility of the sputum containing tuberculous germs and with the still more remote possibility of its proving a source of infection to others, surely it would sustain a law penalizing the transmission of a serious disease. The mere existence of such a law upon our statute books would do much to educate the conscience of the public to the idea that the transmission of syphilis is not a venial offense—that it is a crime against society to recklessly scatter the seeds of a loathsome disease. Responsibility for the spread of syphilis should be narrowed down to the question of individual accountability. Such a law would have its special application in the protection of minors.

Safeguarding Minors.

The Committee is convinced that no successful preventive measures against the dissemination of venereal diseases can be instituted which do not take into consideration the necessity of throwing special safeguards around minors. Statistical evidence proves that the existence of venereal morbidity falls most heavily in the latter half of the second decade of life. The large proportion of infections occur from the sixteenth to the twentieth year in women, and from the eighteenth to the twenty-third year in men. The statistics of Le Pileur in which the age of contamination in 718 syphilitic women was definitely traced indicates that 62.9 per cent. were infected from the sixteenth to the twentieth year, 6.3 per cent. from the twelfth to the fifteenth year. These statistics show that the débutantes on the stage of vice, the young and the immature, are the chief victims as well as the chief sources of contagion to others. All experience shows that the large proportion of infections may be traced to young prostitutes; old prostitutes are less dangerous in disseminating disease, as many are immunized by time so that they cannot transmit syphilis. Besides they are less attractive and therefore less

sought after. In this country we have no statistics showing the age of contamination, but there are abundant indications of the precociousness of the youth of this city in acquiring venereal disease. All physicians who have charge of venereal clinics have been impressed with evidences of the growth of juvenile vice in this city. The statistics of Dr. Graenelli of the Good Samaritan Dispensary show an increase of from 8 to 15 per cent. of venereal disease in males below eighteen years of age within the past three years.

With a view to suppressing the prostitution of minors a law raising the age of consent would be an additional safeguard. Prostitutes of minor age when apprehended should be sent to a protectory or reformatory and detained until the age of twenty-one.

No less important is the rigid enforcement of the law against proxenetism. The procurer must be regarded as a most active agent in the dissemination of venereal disease. The business of procuring young and innocent girls for introduction into a life of debauch where they are almost inevitably doomed to contract and spread venereal disease is a crime which has its hygienic as well as its moral aspects. The law should provide the most rigorous enactments to fittingly punish the panderers to this vile trade.

Education and Treatment.

Among the miscellaneous measures proposed the most important may be grouped under the head of education and treatment with enlargement of hospital and dispensary facilities. In the opinion of the Committee, education and treatment comprise the most promising remedial measures which are immediately available and which all interested in this hygienic work, the repression and control of the effects of prostitution, will approve. They take cognizance of the rôle played by men in the progagation of venereal disease, as they apply to both men and women.

Education should begin in the ranks of the profession. In the organization of the system of instruction in many of our medical schools, the importance of a knowledge of this class of diseases is not recognized. The study of venerology should be made an integral and essential part of medical education, and the practical as well as theoretical knowledge of this disease should be made an indispensable requisite for graduation in medicine. The importance of deciding intelligently upon the conditions of admissibility to marriage of venereal patients, for example, cannot be overestimated. The dangers introduced into the family life by the premature marriage of a syphilitic man, or of a man suffering from a latent urethritis, to which the sanction of the physician may have been given, involve a heavy responsibility upon the medical profession. How many thousands of young men with an uncured gonorrhea every year enter into the state of matrimony, it may be with the sanction of the physician who has made perhaps a superficial examination, and infected their wives, resulting in pyosalpingitis or peritonitis and ending in chronic invalidism and hopeless sterility. Speaking of this class of cases, Dr. T. Gaillard Thomas says: "Specific vaginitis transmitted to virtuous women by men who are utterly ignorant of the fact that the sins of their youthful days are at this late period bringing them to judgment, is one of the most frequent, most active and most direful of all the causes of serious pelvic trouble in women—one which meets the gynecologist at every turn and one which commonly proves incurable except by the dangerous procedure of celiotomy." . . . "A marital quarantine is as necessary to-day in social life as a national quarantine is for contagious diseases in general."

Those charged with the education of young men in high schools and colleges should instruct them as to the dangers of promiscuous intercourse. Every young man should be impressed with the idea that venereal disease is almost invariably a concomitant of licentious living, involving consequences which may seriously compromise his health and like an avenging nemesis come to smite him, it may be, years after he has forgotten his youthful follies. This knowledge should be imparted with tact, discretion and good sense. The physician would prove a most valuable auxiliary in this prophylactic education. Especially should he correct the traditional belief so universally accepted by the laity that gonorrhea is a trivial affair, easily cured and leaving no permanent results. He should also combat the dangerous theory that sexual indulgence is necessary to health. As Sir Wm. Gowers has said, "No man was ever worse for continence or better for incontinence." All medical men as well as moralists who have studied this question look upon the promotion of masculine chastity as among the most powerful means of checking prostitution. Prostitution is largely a matter of supply and demand and all conditions which diminish the demand for prostitutes on the part of men diminish the supply.

One of the most effective means at our command for preventing the dissemination of venereal disease is to sterilize promptly the sources of contagion by treatment and thus shorten the period of their contagious activity. The number of infections that may be traced to a single source is often most remarkable. Every venereal patient should be looked upon as a possible focus for the spread of contagion, and the cardinal consideration should always be kept in view that the protection of others from risk of infection is quite as important as the cure of the disease. The patient should be fully instructed as to the nature of his disease, the duration of its contagious activity, the manifold means by which contagion may be effected, and the moral responsibility involved in exposing others to contagion. Every source of contagion suppressed by treatment, every infection avoided by enlightenment of the patient represents a distinct gain in the reduction of venereal morbidity. Education along these lines should be generalized as much as possible

among the public, especially among the poor and ignorant. In order to prevent blindness from neglected ophthalmia neonatorum among the poor, midwives should be instructed as to the cause, symptoms and dangers of this affection and the necessity for prompt and skilful medical treatment.

The Committee has already referred to the ban of ostracism which dishonors this class of diseases in their exclusion from general hospitals in this city, and would recommend that every general hospital receiving State or municipal assistance should be required to open its doors to this class of diseases. Fortunately, hospital care is not required in the large proportion of venereal diseases. Most of them are ambulatory cases, and dispensary treatment which does not interfere with their employment and with their wage-earning capacity is best adapted to their requirements. While only a limited number of dispensaries in this city have a venereal service, it has been found that patients are treated in a large number of dispensaries which ostensibly do not receive this class of cases. This treatment should be efficient and at the same time available, the attending physicians of the venereal classes should be specialists in this branch of medicine, and the service should be organized and conducted with especial reference to the nature of the disease, that is, they should be conducted with all the privacy possible.

Among the subsidiary measures which are recommended are the absolute prohibition of all advertisements of "infallible cures" by charlatans in the public press and the placing of advertisements of "sure cures" for private diseases near urinals or in public places, also the prohibition of prescribing for venereal diseases by druggists.

In concluding this report it may be said that the closing years of the nineteenth century have been marked by a general awakening of interest in the chronic infectious diseases, tuberculosis and syphilis, and the convocation of international conferences for the discussion and adoption of the sanitary measures best adapted to their repression and control, as exemplified in the Congress for Tuberculosis and the Congress for the Prophylaxis of Syphilis and Venereal Diseases in 1899. It is now generally recognized that the ravages of these chronic infectious diseases are infinitely more destructive to the human race than cholera, smallpox, or the plague, and that their prophylaxis should no longer be neglected.

The object of this Committee's work has been to ascertain, with some approximation to accuracy—the amount of venereal morbidity in this city, to stimulate the interest of the medical profession in this important but neglected class of diseases, and to urge the employment of all the resources of sanitary science to limit or prevent this spread.

It will be seen that no specific "State or municipal legislation for the repression and control of prostitution," as was contemplated in the resolution of the Society creating this Committee, has been recommended, and this from the firm conviction that such repressive measures would prove a failure. Because the source of venereal diseases cannot be extinguished there is no reason why we should shut our eyes to their existence and fold our arms in the helplessness of impotency. By a parity of reasoning it might be contended that because we cannot destroy the causes of acute contagious diseases we should cease to combat their spread.

While the Committee does not indulge in the Utopian idea that the extermination of venereal diseases is likely to prove entirely successful, it is fully persuaded that much may be done to limit their dissemination by intelligent and well-directed sanitary effort.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK AND ITS OBJECTS.[1]

BY FRANK VAN FLEET, M.D.

TO-NIGHT, for the ninety-sixth time, the members of this Society meet to inaugurate a new president and to listen to his promises to preside over their deliberations for the coming year and to protect their interests and the interests their Society represents to the best of his ability, honestly, faithfully, and impartially.

Without doubt, each newly-elected president has accepted this trust with a keen appreciation of the responsibilities resting on his shoulders and with a determination so to conduct the duties of his office that, when he shall hand the gavel to his successor, all shall say, "Well done." Such is the feeling of the present incumbent as regards himself. He looks upon the position of president of the Medical Society of the County of New York as one of the most responsible positions a physician, in his capacity as a medical man, can hold. The president of the Medical Society of the State of New York must feel that it is a part of his responsibility to see that each county in the State has a medical society, and that each of these societies is doing its utmost to protect the interests of the profession and of the public health of the county it represents. His duties and responsibilities, therefore, cover a greater area than the president of any one county society, all of whom are subordinate to him. The Medical Society of the County of New York is but one of the societies going to make up the system which has as its head the Medical Society of the

[1] Inaugural Address by the President of the Medical Society of the County of New York, November 25, 1901.

State of New York, and its duty, given it by the Legislature of the State, is to look after and protect the public health of the county whose name it takes.

This county, however, while it is but one of the sixty counties in the State, covering only about eighty square miles,[2] while the State covers fifty-three thousand, seven hundred and nineteen square miles, contains nearly one-fourth of the entire population of the State.[3]

The Medical Society of the County of New York, therefore, while only a part of the State Society, is still so important a part and represents so important a part of the State of New York that the parent body listens with great respect to the voice of our County Society. The president of the Medical Society of the County of New York presides over a body which, while perhaps not more important than the body over which his predecessors, in the early days of the Society, presided, is many times larger. In 1806, when the Medical Society of the County of New York was organized, the city of New York had a population of 80,000[4] and the membership of the Society was about 100; now the membership is nearly 1,700. A closer study of the figures will show us that, while we are larger in actual numbers, we are not larger proportionately. In the early days the membership in the Society was in proportion to the population of the city, as one in eight hundred, while to-day the proportion is about as one in ten hundred and eighty-eight. In the early days of the Society membership was compulsory; the Society was organized by the Legislature for the purpose of "regulating the practice of physic and surgery," and all physicians were directed to associate themselves with the Society, and the Society was authorized to collect a certain sum of money annually from each practising physician to defray the expense of regulating the practice of physic and surgery." To-day membership in this Society is not compulsory, but the doors are open to all reputable practitioners of medicine who are willing to declare their abnegation of sectarian principles and practice. Not that the applicant must declare that he will never resort to any one particular method of practice; that in itself ought to debar a man from membership in any society. It is certainly as illogical for a physician to declare he will not employ a particular system of practice, or a particular remedy or method, as it is for him to say that he will use no other. The Medical Society of the County of New York aims to include in its list of members all reputable practitioners of medicine who are willing to assert that they are not bound to practise any exclusive system. We call ourselves the "Regular" profession because we are the representatives and direct successors of the profession which has existed since the dawn of civilization, and because our practice is broad enough to include all schools, all systems, and all methods of treating disease which offer to humanity the possibility of relieving or curing the ills to which it is heir.

Our Society is in no sense a club, and no member has the right to object to the admission of any reputable physician because the applicant may not be personally acceptable to him. Personal dislikes should have no part in the determination of one's fitness for membership in this Society. In the days when membership in this Society was compulsory there were but one class of practitioners. When Homeopathic and Eclectic practitioners became numerous and powerful enough, the law compelling membership in this Society was repealed, and societies representing these other schools of practice were authorized by law, with privileges identical with those enjoyed by this Society. No clause was inserted in any subsequent law making membership in any society compulsory, but privileges are granted members of three societies, representing the three legal schools of practice, which are not enjoyed by physicians who are not members of these societies.

The medical profession of the State of New York is legally represented by three State medical societies representing the three legal systems of practice in the State, the Regular, the Homeopathic and the Eclectic. It is well to keep this constantly in mind, because there are no other societies or associations which have ever been created by law endowed with the privileges and functions of these three societies. These three organizations stand as the representatives of the medical profession in this State and are so recognized by law. Membership in the society representing the Regular profession, that is, the Medical Society of the State of New York, is determined by the applicant having served as a delegate to the State Society, and to be a delegate it is necessary to be a member of a county society in affiliation with the State Society. It is the privilege of every reputable physician to aspire to any position which a physician, by virtue of his being a physician, can hold. Among these positions is that of being a member of the State Board of Medical Examiners. The members of this examining board representing the Regular profession must be taken from the membership of the Medical Society of the State of New York. If a physician is debarred from membership in a county society he is denied the privilege of being a member of the State Society, and accordingly it is impossible for him to aspire to membership in the State Board of Medical Examiners. Therefore, a physician who desires membership in the representative medical society of the county in which he resides has a legal right to admission if he complies with the legal requirements. The law gives the county societies the

[2] New York City contains 308 square miles. New York County, comprising the Boroughs of Manhattan and The Bronx, contains about 80 square miles: Manhattan 19.65, and The Bronx 60.00.

[3] The population of New York State, according to the census of 1900, was 7,268,012: New York City 3,437,202; New York County 2,050,600. A small portion of The Bronx is in Westchester County, but the population of this small section does not materially affect the deductions drawn.

[4] In 1805 the population of New York City was 75,587; in 1810 it was 96,373, so that in 1806 we estimate it to have been about 80,000. In 1806 the city was situated entirely on Manhattan Island; this portion of the city is now known as the borough of Manhattan. The population of this borough, according to the census of 1900, was 1,850,093.

right to make by-laws for their own government, and a by-law governing admission to membership is one of these. The law says, however, that these by-laws shall not be inconsistent with the laws of the State, and to deny a person the right to become a member of a county society providing he is legally qualified to be a member is to deny that person one of his inalienable rights, guaranteed him by the Constitution. If a physician voluntarily ostracises himself by refusing to become a member of a county society because some of its by-laws may be repugnant to him, that is his fault; he has a legal right to membership, and it would seem as if the proper course for such a person would be to join the society and then endeavor to secure alterations in the by-laws to have them conform to his ideas.

The Medical Society of the County of New York, representing, as it does, the Regular medical profession, should be made as great a factor for the good of the community as it is possible to make it. Its influence will be in proportion to the number and energy of its members. A society with seventeen hundred members, working hand in hand for the uplifting of the profession and the protection of the public health, would exert double the influence if it had double the number of members. A physician can never reach the ideal of professional attainment unless he adds to the ordinary round of professional work something which will benefit his fellow-man. This is an aphorism which will apply to people in all walks of life, but with greater force, possibly, to medical men than to any others.

Artisans, merchants, financiers, and others find fields for doing good, but generally outside the fields in which they labor for their daily bread. The mechanic, who, with his inventions, opens up new fields of industry, provides new positions for his fellow-mechanics. The merchant and financier open up new fields for the investment of surplus funds, increasing wealth and giving greater opportunities to themselves and to those who come after them. The physician, who studies and delves deep into the sources of disease, does not do this in order to increase disease, but on the contrary, to decrease it. If he labors honestly, as most physicians do, his work tends to decrease the opportunities of those who come after him. Every effort he puts forward to decrease disease robs himself or some colleague of their means of livelihood. No physician stops at this, however; in a manner utterly incomprehensible to the average commercial mind, he plods on, putting obstacles in his own path, waging a war of extermination on his allies, destroying his own avenues of wealth, in order that his non-medical fellow-man may have more comfort and happiness. Our calling is distinctly not commercial, and there is none more Christ-like than that of the true physician.

That medicine has a commercial side is possibly true, but the medical man who turns his attention solely or chiefly to the commercial side fails to see the beauty of his profession, fails to realize the responsibilities of his calling, and lives a life which adds nothing to the world he inhabits. The man who enters the ranks of the medical profession, therefore, has a duty in protecting the community which he cannot turn his back upon and be true to himself, and in no way can he fulfil that duty to greater advantage than by becoming a part of the Society which is the recognized representative of his profession, and by his presence, and his voice and efforts, strengthen its hands and aid it in accomplishing the work for which it was established. And so it seems to me that, while there is no law making membership in this Society compulsory, every physician who is eligible is under a moral obligation to become a member, and to do his utmost to increase the Society's membership, and in that way increase its power and usefulness. It seems fitting and proper that your presiding officer should, as briefly as possible, lay before you the objects he hopes, with your aid, to accomplish during the year, and the methods he expects to employ.

We shall endeavor during the coming year (1) to increase the membership of the Society; (2) to protect the community by the enforcement of the medical law; (3) to present papers which will be attractive and instructive, and to encourage discussions which will keep the Society in the front ranks of scientific bodies; (4) to create a friendly feeling between ourselves and forces which are now antagonistic to us, to the end that our sphere of usefulness may be increased and that we may have a united profession.

The first object of the Society during the coming year will be *to increase the membership of the Society*. There are at least four thousand physicians in the County of New York and of these about seventeen hundred are members of this Society. According to the Transactions of the Homeopathic State Society there were 1,256 Homeopathic physicians in this State in 1898 and of this number 326 practised in New York County, being 25 per cent. of the total number practising in the State. In 1899 and 1900 the number of Homeopathic physicians admitted to practice in the State was 105. If 25 per cent. of these physicians came to New York County to practise they would swell the total of Homeopathic practitioners in this county to 352. In this same period of two years there were 37 Eclectic physicians admitted to practice and 1,178 Regular physicians. Of the 1,320 physicians legally admitted to practice in this State in 1899-1900, 89 per cent. were regular practitioners and eligible to membership in county medical societies like ours. If this percentage is correct, and it certainly is for the two years mentioned, it follows that 3,500 of the practitioners of medicine in this county are of the regular school and eligible for membership in this Society. Of course, there are some whose membership is not desired, for various reasons, but if we eliminate these there are still remaining a great many medical men who are desirable who are not members of this or of any medical society.

There are a great many medical men, good, honest and worthy members of the profession, who are not members of medical societies because they do not understand the value of such membership. We all know medical men of this class, and we could secure the membership of some of them if we would take the trouble to point out to them the reasons why they should associate themselves with this representative body.

These reasons are many, but among them we may enumerate, first, that this Society is engaged in uplifting and protecting the profession of which these men are members and to which they owe a certain allegiance. Whatever may be the opinions of non-medical members of the community concerning laws regulating the practice of medicine, there are few professional men so blind that they cannot see the many advantages, both to themselves and to the community, of such regulations, and it is a just cause for pride on the part of the members of this Society to know that the Medical Society of the County of New York played no small part in securing the enactment of the laws creating the present high standard of medical requirements in this State.

A second reason why every medical man should be a member of this Society is that the burden of the enforcement of the medical laws falls on this Society. The State gives certain privileges to members of the medical profession which are not enjoyed by other citizens, and in return the State imposes certain obligations on the profession which no member has the right to shirk. If it is so distasteful to one's inclinations, or for other reasons impossible that one should enter actively into the work of this Society—which stands between the public and incompetent medical practitioners—there is no reason why such a person should not join the Society and at least give moral support to those who are endeavoring to carry on the work of the Society, some of which may be distasteful to them, too.

A third reason for becoming a member of this Society is that such membership is a support in time of trouble. Members of the medical profession are especially liable to the attacks of unscrupulous or misguided people who think they have grievances—suits for malpractice, unjust accusations against a physician's character, and many other troubles which may come to a doctor's lot. No medical man is safe from attacks of this kind, be he ever so honorable, or let his position be as exalted as possible. Membership in this Society may not prevent these attacks, but the member of the representative medical society of the county in which he lives, the associate of men of known respectability and honor, stands a much better chance of receiving justice than the man, who, in a county having four thousand practitioners of medicine, stands alone. The first question which occurs to everybody in connection with such a person is, Why has he not associated himself with the County Medical Society?

These reasons can be multiplied many times. It seems to me that the duty of every member of this Society to see that every medical friend is also a member is second only to the duty of the friend to become a member, and your presiding officer for the coming year takes this opportunity to urge every member to do missionary work among non-members for the sake of the Society, for the sake of the individual, and for the sake of the community at large.

The second object which will engage the attention of the Society during the coming year will be the *enforcement of the medical laws in this County.* This work has been carried on by the Medical Society of the County of New York whenever it has been carried on at all. When the present laws were enacted it was intended that the county medical societies having representation in the three State societies representing the three legal systems of practice in this State should be the organizations authorized to secure the enforcement of the law. The law is worded so that when the section conferring this power is read alone, it appears as if any incorporated medical society of the State had the right to undertake and carry out this work, but when all the sections are read in their regular order the intent of the law, as I have stated it, appears very plain. The Appellate Division of the Supreme Court has decided that this section of the law should be read alone, without, however, giving any reason for such an interpretation. The County of New York would not appeal from this decision, and we could not. Under this decision any incorporated medical society of the State has the right to undertake the work of securing the enforcement of the medical law, and to claim the fines imposed. The only organization beside ours which has undertaken this work up to now is the New York County Medical Association, which has secured three convictions this year. Our Society has been doing this work for so long a time that we have come to be looked upon as the authorized agent for the enforcement of the law. Our counsel acts for the District Attorney's office, and to introduce new societies into the field, with new counsel, will be to introduce confusion. Rival societies conducting prosecutions of violators of the medical laws, each anxious to outdo the others in securing convictions, may result in injustice being done and give the appearance of persecution instead of prosecution, will disgust the courts, thus making convictions of actual offenders more difficult, and will increase the cost. The cost of conducting this work is no small item. Seven years ago it cost this Society one hundred and forty-five dollars to secure a conviction. During the year just closing it cost seventy-nine dollars, and for the seven years it has cost an average of eighty-eight dollars for each conviction. Of course, the whole of this does not fall on the Society, as the fines paid are turned over to us; if we deduct the fines received, the cost to the Society for the past year was twenty-two dollars for each conviction. We maintain, under the supervision of the Board of Censors, a system with a prosecuting attorney at its head for the enforcement of the medical

laws in this county. Complaints of violation of the law are numerous, and in order that no injustice may be done every complaint received is carefully investigated before any definite action is taken. To make these investigations the counsel has in his employ a number of detectives. The cost of this law bureau averages about two hundred and fifty dollars a month. As we have said, this outlay is partly offset by the receipt of the fines imposed on convicted violators, but the excess of expenditures over receipts by the most economical management will average at least fifty dollars a month. As our system has been perfected the cost has been reduced, and we hope soon to reach a stage when the expenditures and receipts will balance. Of course, if we are compelled to divide this work with other organizations, the receipts will be diminished and the net cost to the Society increased.

We have labored under a disadvantage inasmuch as a decision was rendered by one of the Judges of the Supreme Court, twenty years ago, that to constitute a violation of the law governing the practice of medicine it was necessary to give medicine or drugs. Lawyers advised that no suits against violators of the law be brought unless a prescription written by the alleged violator, or medicine given, could be put in evidence. We contended that the practice of medicine was the treating of disease, regardless of the method employed, and during the last session of the Legislature we endeavored to secure an amendment to the law which would make this plain. We failed in this, but we aroused public sentiment to such an extent that one of our city judges put us in the way of securing a conviction in the case of a so-called "astrologer" who treated a patient who had a fistula *in ano,* with electricity. Our counsel worked up this case and, notwithstanding the fact that the defendant moved a dismissal of the case on the ground that no violation of the law had been attempted because no medicines or drugs were used, the defendant was convicted of violating the medical law and paid a fine of two hundred and fifty dollars. The Judges who rendered this decision and imposed the fine were Justices Holbrook, Jerome and Hinsdale. This decision settles the question of what constitutes practising medicine unless the decision is reversed in some other case.

It is a cause for congratulation on the part of the members of this Society that the enactment of the present medical law was secured through the efforts of our system of medical societies, and it is a fitting climax that this Medical Society of the County of New York secured the conviction which demonstrated that this law is broad enough to cover all unregistered practitioners who treat disease, regardless of the method they employ.

The third object which will engage the attention of this Society during the coming year will be the *reading and discussing of scientific papers.* We have succeeded in obtaining the promises of leading members of the profession to read papers and take part in our discussions which will ensure meetings replete in interesting and instructive matter. Each meeting will be devoted to the discussion of some one subject, and members of the profession, not only from our own city, but from other parts of the United States, will be requested to take part. The December meeting will be called the orthopedic meeting. The January meeting will be the gynecological meeting. The February meeting will be the State medicine meeting. The March meeting will be the medico-surgical meeting. The April meeting will be the ophthalmological meeting. The May meeting will be the genito-urinary meeting. Following the summer vacation the September meeting will be the otological meeting. In October will be the annual meeting and no papers will be presented. The November meeting will be the inaugural of the new president.

The Milk Commission of our Society which has done good work will be continued, as directed by the Society, and the Society will be kept informed of the work done.

And now, fellow members of the Medical Society of the County of New York, I approach the consideration of the fourth object which in my judgment we should have in view, with hesitation, not because I am opposed to its consideration, but because of the fear that what I say may be misconstrued and misinterpreted. The necessity for its consideration, however, is so positive that I feel I cannot conscientiously avoid it. This object is *the creation of a friendlier feeling between ourselves and forces which are now antagonistic to us to the end that our sphere of usefulness may be increased and that we may be a thoroughly united profession.*

It is folly to deny that any unfriendly feeling exists between the members of the Society and the Association. That over sixty-seven per cent. have not this feeling may be true; over sixty-seven per cent. of the membership of the Association is made up of members of this Society, and it is difficult to imagine a man having a genuine feeling of antagonism for himself. There are, however, a few who have bitterness enough to disturb the whole profession. Many of the members who pay dues to both organizations do not understand the cause for the existence of both bodies. They join both because of friendship for other members, for social reasons, for business reasons, and so on. I have many warm personal friends who are members of both; indeed, some of my intimate acquaintances are members of the Association and not of the Society.

This division had its origin when the Medical Society of the State of New York modified its by-laws so as to change the code of ethics of the American Medical Association, which had hitherto been the code of the State Society. The State Society finally abrogated all written codes, in which condition it remains to-day. The minority in the State Society, after this body had reaffirmed this action for three years in succes-

sion, retired and organized the New York State Medical Association in order to uphold this code. This code defined what should be the attitude of the members of the profession to each other and of the profession to the public. It also undertook to instruct the public as to how it should treat the profession. It would seem as if it were unnecessary to tell members of the profession, who are supposedly and generally are gentlemen how they should treat each other or how they should treat the public. Members of a learned profession should treat each other as gentlemen, and should assume to the public the attitude of honest men; it ought not to be necessary to have a code to tell us this. The public, on the other hand, while it has a high regard for the medical profession, looks upon the profession as a sort of necessary evil. The public consults the profession when in need of medical advice, and pays for the advice a financial consideration, and that is all it cares for the medical profession.

These items, however, the opponents of the code could have passed over, but the code went farther, and declared that no regular practitioner should meet in consultation any practitioner who held views on therapeutics at variance with his own. This was intolerable, and the State and county societies finally refused to be governed by it. As a consequence the American Medical Association declined to receive delegates from the State and county societies. As we have said the State Association was organized to uphold this code. Men have become members of the Society, thus endorsing the views of the Society, and have then joined the Association and subscribed to the very code their membership in the Society has stamped them as being antagonistic to. Other States, we are told, have refused to accept the principles of the code, and their delegates have been received by the American Medical Association, but the delegates of the Medical Society of the State of New York, the representative of the medical profession in the Empire State, a Society whose honorable career is approaching the century mark, is debarred, because it refuses to subscribe to a code of ethics which is, admittedly, a dead-letter.

This is the history of the past. It has come to us from various unofficial sources that the American Medical Association has been reorganized so that the question of code does not come into its membership. In the absence of official information we cannot be sure that this is true, although it is stated as a fact in order to induce members of our Society to join the Association that there is no difference now on the code question. If this be so, since the New York State Society's delegates were excluded simply because they would not subscribe to the written code, it would seem, now that this is no longer necessary, that the American Medical Association would be glad to receive our delegates. If there be reasonable ground for supposing that our delegates will be received, as representatives of the regular medical society—one of the oldest if not quite the oldest in the Union—I recommend that the State Society be requested by the Medical Society of the County of New York to take some steps looking toward an adjustment of the differences which now exist. It seems to me there is a necessity for the existence of a National body; there are desirable conditions which should be brought about, which cannot be, except through the concerted action of various State medical societies acting through a central body.

We have, for instance, a standard of medical requirements in nearly every State, and yet, although these requirements are similar, the right conferred to practise medicine in one State gives the person possessing it no privileges in another State. Men who have practised medicine in one State, possibly for years, reaching positions of honor and respect which have placed them in the foremost ranks of the medical profession, cannot transfer their positions and possibly achieve greater renown in other States unless they undergo technical examinations which nobody but recent graduates can hope to undergo successfully without considerable preparation. I do not wish it understood that I object to State medical examinations, for I am heartily in sympathy with them; I do think, however, that it is not good to overdo the matter of State examinations. I do not think the standard should be raised too high, and I am inclined to the belief that it has been raised in this State as high as it should be raised. I do not think our standard is too high, or that it should be lowered to meet the requirements of other States. I believe the standard of other States should be raised to correspond with ours, and that the person possessing the right to practise in one State should have the right to practise in any State in the United States. In other words, there should be reciprocity between State examining boards, and this can only be brought about through the efforts of a National body made up of medical societies in interested States. There should also be in this country a National Bureau of Public Health, with a physician at its head, who should be a member of the Cabinet of the President of the United States. This, too, can only be brought about through the efforts of a National Medical Society.

The American Medical Association is in the field; its first meeting was held in the City of New York and the Medical Society of the State of New York was party to its organization. We have become estranged and it seems to me that some steps should be taken to bring about a reconciliation, if it can be honorably accomplished. The unity of the profession and representation in the American Medical Association are objects well worthy of attainment, but nothing on this earth is worth the sacrifice of honor.

A search through the proposed new constitution and by-laws of the American Medical Association fails to reveal anything of a code of ethics, and we have been informed that if our members presented themselves as delegates to the American Association they would not be

asked to subscribe to a written code or creed. We are told the only obstacle in the way of delegates from our Society being recognized by the American Medical Association is the presence of the New York State Medical Association, which is the body in affiliation with the American Medical Association, and the National body cannot recognize two organizations in one State.

There can be no greater compliment paid to the Medical Society of the State of New York than that other organizations have adopted the plans and ideas promulgated by the State Society. Medical examining boards in nearly every State in the Union are copied after our State board, which is largely the creation of our State Society. Our system of organization, comprising a central body or head, with county or subordinate branches sending delegates to make up the central body, has been adopted by other State societies, including the New York State Medical Association, as well as the American Medical Association. This system has been our plan of organization since 1806. One of the prominent members of the American Medical Association, whose name I am not at liberty to divulge, in writing to me, says: "Nearly all the States have followed the example of yours in reference to laws regulating the practice of medicine, and in all these States our members of Boards of Examiners violate the letter of the code in signing certificates for irregulars. Your State was simply unfortunate in being the first to take this step and thereby bring down upon it the censure of a few of the strict code men in the Association." Our State Society has been criticized for taking the step of abolishing the code of ethics too soon, our critics contending that the same thing would have been accomplished in the end without any difficulty if matters had been allowed to take their course. However this might have been, whether our action in 1882 led to the accomplishment of what we have been told has been accomplished—the abrogation of the code by the American Medical Association—or whether this would have been the natural course of events regardless of our action at that time, is not for us to say. It is sufficient to know that this has been accomplished—if it has been—and that there is now no difference in this particular between the Medical Society of the State of New York and the New York State Medical Association.

I cannot believe it is the proper course to pursue for members of the Society to become members of the Association in order to become members of the American Medical Association. If the doctrines promulgated by our Society have been adopted by others, and if our system of organization is, in the main, that on which the reorganization of the American Medical Association has been accomplished, it seems hardly fair that our members should be asked to affiliate with a younger medical body, and that the claims of the older organization should be ignored. At the same time it is not to be expected that the younger body should yield everything to the older. There should be some common ground on which the advocates of both organizations could get together and determine what, if anything, can be done. My recommendation is this: That the Medical Society of the County of New York appoint a committee to confer, if possible, with other organizations, to ascertain if an amalgamation of the Society with other societies and associations cannot be accomplished on terms satisfactory to all concerned, and that this committee report to the Society at the stated meeting in January, or sooner, in order that some recommendation may be made to the Medical Society of the State of New York at its next annual meeting.

Gentlemen, and fellow members all, in conclusion let me say that I am not one who believes in rejecting overtures of peace. I would hold out the right hand of fellowship to any member of the profession who is respectable; indeed, I would go farther; I would present the olive branch to our colleagues in other organizations which have been opposing us. I would be willing to make concessions, and would exhaust every honorable means to bring about a reconciliation; but, if our efforts are spurned, we of this Society—which is venerable in years and honorable in reputation—must go on in our own way, being true to the Society and to ourselves, and from other States men will flock to our banners—as I am informed they are willing to do now—and we can not only build up and tional body which will fulfil the purposes for strengthen our Society, but we can create a Nawhich such a body should be created, namely, to uplift the profession and to protect the public health.

THREE POINTS IN THE TREATMENT OF THE DEFORMITIES OF INFANTILE PARALYSIS.[1]

BY JOHN LINCOLN PORTER, M.D.,
OF CHICAGO;
PROFESSOR OF ORTHOPEDIC SURGERY, COLLEGE OF PHYSICIANS AND SURGEONS, UNIVERSITY OF ILLINOIS.

INSTEAD of following the synopsis of this paper as outlined in the program and discussing the pathology and operative technic of these conditions, I shall confine myself to a few words on the treatment of the deformities of infantile paralysis. It is not because I have any new ideas to offer that I am induced to take up this subject, but because certain small details, so often overlooked or forgotten in the management of these cases, are worthy of more careful attention, and because the sufferer from infantile paralysis is entitled to the benefit of every therapeutic measure that can possibly improve his condition. And at this time, as a further preface to what I shall say about treatment, permit me to add that every case of in-

[1] Read by title at the meeting of the Illinois State Medical Society, Peoria, Ill., 1901.

fantile paralysis is sure to result in some deformity sooner or later, and that the chief factors in the production of these deformities are the atrophy and loss of power of the paralyzed muscles and the consequent contraction and shortening of the active and unopposed muscles. Bearing in mind these facts, I wish to emphasize three points in the treatment of these deformities.

The most efficient treatment of the deformities resulting from infantile paralysis is the preventive treatment. Infantile paralysis is the cause of about 35 per cent. of the deformities of the lower extremities that come to the orthopedic clinics. In a very large part, if not all, of these cases, the deformity could have been prevented if treatment had been begun earlier. Rarely does a case come to the attention of the surgeon until the contractures and deformities are marked. I think I am safe in saying that I have never seen a case of infantile paralysis within six months of the acute attack; usually it has been years afterward.

Treatment should be begun as soon as the extent of the paralysis is well defined, for we can then predict almost definitely what the resulting deformity will be. The parents do not realize this because their whole concern at that time is with the paralysis and their thoughts are occupied with trying to find something, medicine, electricity, massage, that will bring back the power in the afflicted limb. We know that to a certain extent that power will never be recovered and, further, we know that contractures of those muscles that are unaffected, and consequent distortions of greater or less extent, are sure to take place. The family should be made to realize this. After recovery is complete and all has been done that can be done to improve the tone of the muscles that are spared, they should be told that, so far as the paralysis is concerned, the account is closed and, if they wish to make the best possible use of the limb and prevent more trouble in the future in the shape of deformities, they must take steps at once to do so.

Human nature is very prone to put up with burdens that come on slowly so that the individual becomes accustomed to them, when the same burden developing suddenly would seem intolerable. So in these cases of deformity which develop gradually the child becomes accustomed to the disability, and the parents, having accepted the fact that the paralysis is incurable, naturally conclude, unless they have been warned, that the resulting deformity is unavoidable.

A boy, eighteen years old, was recently sent to me for scoliosis. As he came into the office, I noticed that he walked with a limp that was not accounted for by any scoliosis. On undressing him, I found a severe, rigid, right dorsal-left lumbar curvature of the spine, and, in addition, the left leg was partly paralyzed and two and one-half inches shorter than the right. The short leg was the sole cause of the lateral curvature. The paralysis had occured at four years of age and had affected nearly the whole leg, but enough muscles were spared to allow him to walk without support and contractures were not severe. He had gone without treatment until he was twelve years old, when the spinal curvature became so marked that the parents began to get ready to do something. He went through various hands for the next six years, including the Kirksville School of Osteopathy, where he boarded for several months to get the benefit of being at the fountain-head. When he came to me his mother said he was worse than ever. Inquiry brought out the fact that no one had ever suggested lifting the shortened leg. They said the doctors had never paid much attention to that leg because they said it was incurable. I assured them that the spinal trouble was also incurable, but that I believed the lad could be much improved by simply wearing a high shoe. This was done and the improvement was so marked

FIG. 1. Showing the brace in the rough before being leather covered and nickeled; the joint at the knee is unlocked. A foot-plate used in cases of varus and worn inside the shoe is also shown.

that I was encouraged to attempt treatment of the spine and eventually increased the improvement already gained. Had the boy begun twelve years before wearing a high shoe to compensate for the gradual shortening, the spinal curvature would never have developed. This brings me to the second point that I want to emphasize.

Every case of infantile paralytic deformity, however slight or severe, can be improved to some extent by appropriate treatment. That treatment may be anything from adjusting a simple ankle-brace to correcting clubfoot, to an extensive tendon transplantation or to the production of an artificial ankylosis of a joint. We are all familiar with the condition in which the anterior muscles of the thigh and leg are affected but those of the calf are spared. As a result the

patient walks awkwardly, throwing the leg forward by the aid of the ilio-psoas muscles and bringing the foot down flat on the floor and fixing the knee by hyperextending it. The center of gravity falls behind the heel and the tense posterior ligaments hold the knee stiff while the weight is thrown forward over it. Often the patient has a habit of fixing the knee with a hand on the thigh. As a result of this constant hyperextension of the joint the head of the tibia is displaced backward and somewhat inward, and the foot becomes extended by the contraction of the soleus muscles.

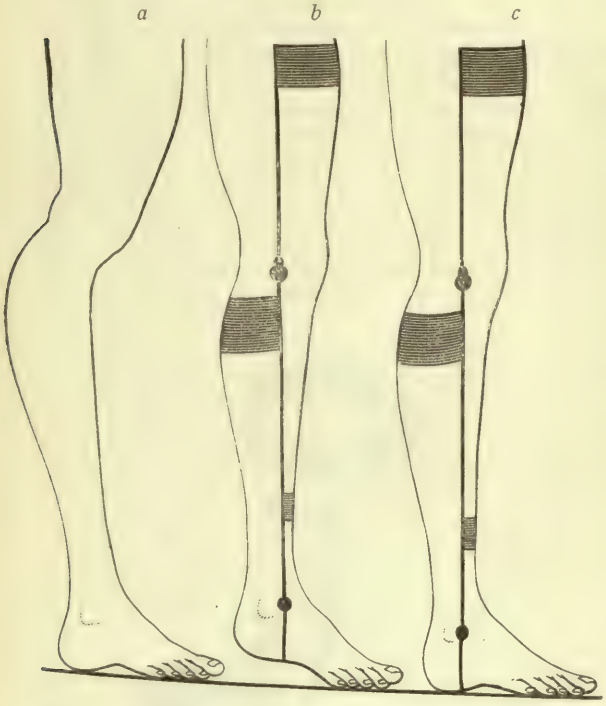

Fig. 2. Showing mechanical effect of brace and tenotomy in the condition described. (Adapted from E. Noble Smith.)

I have had this unfinished brace made for a little patient of seven years with exactly that condition. It works thus: A bearing-point is made on the anterior surface of the thigh by means of this spring-steel band which passes half round it, another is fixed in the same way just above the ankle, then the leather strap is passed behind the head of the tibia just below the knee-joint and thus the tibia is drawn forward by tightening the strap. Sometimes this can be accomplished quite rapidly; at others it takes several weeks, the strap being drawn a little tighter every few days. The bands at the thigh and ankle are completed by leather straps which buckle around the leg to hold the splint in place. At the knee a ring-catch joint is made so that the patient can sit down. When he rises to walk the ring drops over the projecting bar and fixes the knee stiff. That is the object—to stiffen the knee artificially in walking and hold it in normal position. But, when the head of the tibia is drawn forward into place, the heel is lifted from the floor by the contraction of the tendo-Achillis and the extension of the foot, so the patient cannot set the foot flat on the floor, but usually has to step on the ball of the foot. (See *b*, Fig. 2.) If now we do a tenotomy of the Achilles tendon, dorso-flex the foot to a little more than a right angle and put it up in plaster of Paris until the wound heals, then with a stop-joint at the ankle the patient can walk with the leg and foot in normal position. (See *c*, Fig. 2.)

This stop-joint allows of flexion to any extent as the body is carried forward, but extension is only possible to a right angle, thus preventing the toe-drop. When there is a tendency to inversion or eversion of the foot, instead of attaching the splint to the shoe, it is attached to a thin steel foot-plate with a flange on the inside or outside according to the condition and this is worn inside the shoe. (See Fig. 1.)

In cases where the posterior thigh muscles are spared, but the anterior ones are paralyzed, exactly the opposite condition exists—the knee is held in slight flexion by the contraction of the hamstrings, and the patient cannot walk at all. Here the same splint can be used by simply reversing the bearing-points and carrying the pressure strap over the knee and doing a tenotomy of the inner and outer hamstring tendons so as to extend the leg. Here the same ring-catch joint may be used or not. If the tendency to contraction in the hamstring muscles is very great it may be better to keep the knee stiff all the time.

Fig. 3. Showing brace adjusted.

The third point I wish to speak of is this: *Simple tenotomy of the shortened tendons in these cases is of great benefit aside from the release of tension and improvement of function that result.*

Every surgeon who has done tenotomies in cases where rigid contractures existed has noticed the marked improvement that takes place in the nourishment and general condition of the limb. Almost immediately in some cases, the leg becomes warmer and looses its blue appearance and not only the muscles that are released from tension improve in function, but some of the muscles that were thought to be paralyzed seem to gain in activity, showing that some trophic, vascular or reflex stimulus has been brought about by the operation.

E. Noble Smith (Paralytic Deformities of the Lower Extremities, 1900, p. 65) says: "The idea occurred to me that as tenotomy of a sound muscle is capable of producing so much improvement in nutrition in a neighboring muscle weakened by paralysis, how much more direct an influence would tenotomy of the affected muscle itself have. Acting upon this idea I have operated in this way upon two patients, . . . " and he goes on to give the histories of these two cases and states that to his surprise the paralyzed muscles in both cases showed some contractile power and the electric formula of degeneration, which had existed before the operation, was changed to one of active response.

Just a word of caution: Tenotomy alone for correction of a deformity caused by contractures is disappointing. Unless the improvement gained by the operation is maintained by proper mechanical apparatus, the contractures and deformity will almost surely recur.

The large number of these cases that we see which have had tenotomies done somewhere at some time and the limb allowed to relapse into its original deformity for lack of after-treatment convinces me that this point is not borne in mind by many who consider themselves competent to operate upon these cases. In dealing with paralytic deformities the essential treatment has but just begun when the operation is finished.

ARTIFICIAL MILKS.

BY LOUIS KOLIPINSKI, M.D.,
OF WASHINGTON, D. C.

MILK is the chief food of mankind. Its consumption is as universal as it is necessary. Without it the young will not thrive. The heavy mortality of early life is due to artificial and unnatural feeding. The infant properly nursed by the mother is the ideal of health and vigor. Milk for the new-born is indispensable.

In the child and adult, milk is no longer a *sine qua non.* A great variety of other foods is consumed varying with race and climate, civilization, habits and the fancies of the gastronomic art. Whilst no longer the sole means of subsistence the rôle of milk in dietetics is a great one. Without it the treatment of many diseases is futile. It remains a complete and perfect food for the sick upon which a wasted body can be revived and fattened. Its sole and persistent use is directly curative. So valuable a product cannot but excite admiration in whatever light it may be viewed. So extraordinary and perfect a combination cannot but produce an impression of harmony and adaptability upon the observing thinker.

Physically milk is the most perfect of emulsions. Chemically, its ingredients are so proportioned as to satisfy every organ of digestion and nutrition. Whilst in the generality of subjects the use of milk in disease cannot be improved upon by any other fluid food, in exceptional cases it cannot be administered for a variety of causes. Some of these are fanciful and the outcome of prejudice, others real and beyond the patient's will or judgment to control.

Amongst fancied objections are the impressions that it causes "biliousness," that it cannot be digested, that it causes constipation, that its taste is repugnant. Real objections of gravity are that in some it produces a diarrhea which continues as long as its ingestion, and in others, attacks of typical migraine. For these various reasons the writer has devised substitutes for milk where its use is thought a necessity, but when the patient's distaste or objections must be considered.

In composing an artificial milk the following conditions were considered. That it should approximately represent all of the component parts of the animal secretion. That the percentages of salts and of water are of vital importance. That the product should be cheap and readily and rapidly prepared. That the ingredients should be easily obtained. That they should be fresh and sterile and that the mixture be palatable. These requisites are fulfilled in the following general formula: Extract of malt (sirupy), one tablespoonful; olive oil, one tablespoonful; roasted flour, two teaspoonfuls; one broken raw egg. Beat up in a bowl or dish with a spoon or eggbeater for three or four minutes. Add by degrees whilst stirring, a tumbler or gobletful of pure cold drinking-water. Season with table-salt. To be taken one or two hours after meals. In hot weather add crushed ice or prepare the whole in a "milk-shaker."

As is apparent, the extract of malt is used to emulsify the oil, and for its diastatic effect upon the flour. The malt should be of thick consistency. The olive oil represents the fat of milk. The egg, the albuminoids, fat and salts of the natural fluid. The table-salt is added for its digestive effect and to improve the taste of the compound. The roasted flour after conversion into dextine and maltose replace the lactose of milk. The proportion of water is necessary for proper digestion and ready absorption.

This general formula is varied and modified in numerous ways, according to the circumstances or indications of any particular case. The

flour may be increased in amount or diminished or omitted. Increased for its soothing effect in intestinal disease, dispensed with where a carbohydrate is not indicated. The olive oil may be replaced by any other fixed oil or fat. Of the former class cod-liver oil deserves particular mention. Not alone for its great therapeutic-dietetic value, but because it has been found that thus administered it is very readily taken and that the great heat spells of summer are not at all an objection to its persistent use. Other more or less eligible substitutes for olive oil are the fixed oils of cotton-seed, rape-seed, sweet almonds, poppy-seed and peanut.

Of fats, unsalted butter and chocolate, a heaping teaspoonful of the first and two heaping tablespoonfuls of the second, will be found useful. In a chocolate milk, of course, the roasted flour is needless. The chocolate should be grated, or in fine powder form.

The flavor of these artificial milks is rich, and the after-taste pleasant. They produce the agreeable, general sensation of normal digestion. They are restoratives for minor forms of temporary exhaustion, muscular or mental. They produce feelings of composure and confidence. The subject's mind and manner, nerve and decision are at their best.

Special uses and effects will be found exemplified in the subjoined cases.

When Milk Cannot be Borne from Idiosyncrasy.

Case I.—A printer, twenty-seven years of age and able to pursue his daily work whilst under treatment, suffered from chronic pulmonary tuberculosis and chronic enteritis with ulceration. This docile and obedient patient, against his own judgment, consented to drink milk. An attack of migraine immediately followed confining him to his bed for a day. Artificial milks were then used; of olive oil, cod-liver oil, butter and chocolate. This is the record of improvement on the first-mentioned preparation all of which he took with great relish.

Height, 5 feet 7 inches; maximum weight at twenty years of age, 110 pounds; 1st day, 110 pounds; 4th day, 110½ pounds; 8th day, 111 pounds; 12th day, 112 pounds; 17th day, 113½ pounds; 30th day, 115 pounds; 40th day, 116 pounds; 45th day, 116½ pounds; 50th day, 117 pounds; 54th day, 117½ pounds.

Mother's Milk Can Be Replaced by the Artificial Milks in Infant-feeding.

Obviously this should only be done in disease or health when the infant is not breast-fed.

Case II.—An eleven-month-old babe, properly nursed and in good health, showed evidence of suffering, by constant screams, restlessness and loss of weight. This unusual behavior of the infant continued for a week. On investigation it was found that the mother was three months advanced in a second pregnancy and that the milk secretion had practically ceased. Starvation of her offspring was the consequence. The following was given with immediate relief and repeated four to six times daily: One-half of a whipped egg; cod-liver oil, one-half teaspoonful; extract of malt, one-half teaspoonful; roasted flour, one teaspoonful. Emulsify and add four fluid-ounces of cold boiled water. Season with table-salt. Give from a large spoon, cup or glass.

Case III.—A woman with an abundance of breast-milk began the use of a nursing-bottle upon her infant of six months. On the approach of hot weather the child developed a severe summer diarrhea and at the end of five weeks the medical attendant considered the case hopeless. Examination showed great emaciation of the body. The gums were deep red and swollen; no eruption of teeth; tongue small and dry. The babe uttered a constant, feeble wail. The abdomen was distended; the lower border of the enlarged liver and the outlines of the intestines were discernible through the shriveled abdominal wall. Feebleness was extreme; the picture was one of "marasmus." The presence of a continued fever which had, perhaps, existed all along made a prognosis unfavorable; tuberculosis being probably the essential cause of the malady. The infant was far too feeble to suckle and was given its mother's milk with a spoon. Four glasses of the cod-liver-oil milk as in the preceding case were administered daily. The emulsion was greedily taken and was very well borne. For five days the general state remained improved—sleep was natural and refreshing; the infant seemed strengthened. There was no change in the body temperature. Death occurred suddenly on the sixth day of treatment.

The emmenagogue action is certain where the proper indications are found. These are in non-pernicious anemias; physical debility from active or latent forms of gastro-intestinal diseases; the scanty or suppressed flow of obesity; incipient and chronic tuberculosis and the constitutional lean habit. In uterine atrophy it may be useful.

Case IV.—A. F., sixteen years of age; pale, weak, and hollow-eyed; figure stooping and manner languid. She has little appetite; feels tired; the peripheral circulation is sluggish. She is probably overworked at school. Menstruation appeared for the first time in traces for two days. November 22-23, 1900. Was given preparations of iron without result. The menstrual flow remained absent until February 10, 1901, when a very scanty discharge was recorded. On March 30, 1901, weight was 85 pounds. On April 1st was directed to take a goblet of artificial milk between meals twice a day. Olive oil was used, and the roasted flour omitted. Menstruated from April 6th to 9th normal amount. The girl's appearance was very much improved within a week. April 13th, weight 87 pounds. May 4th in lighter clothing weight 87½ pounds. May 6th, normal menstruation.

Case V.—A woman of thirty-nine years, mother of two children, the oldest eight years of age. Her health has been good for a long time, excepting attacks of acute bronchitis and of

spasmodic asthma. Has of late grown stout. Maximum weight, 158 pounds; height, 5 feet 2 inches. Menstruation did not appear in August, 1900; general state, normal. Gynecological examination showed healthy adnexa, the uterus slightly enlarged; position normal, cervix slightly lacerated; no leucorrheal or other discharge. There were none of the nervous and none of the local symptoms of the menopause. It was, therefore, assumed that the menstrual molimen had ceased as a result of obesity. Dietetic treatment for the reduction of the increasing weight did not seem indicated because of her general good health. Various remedies were given to restore the flow, but without result. The period formerly appeared in the first week of the month and continued three days. For this reason the olive-oil milk was taken twice a day beginning on June 1, 1901. She began to menstruate on the 17th—duration of flow three days. Emulsion resumed July 1st, flow began July 10th. In August she did not find it necessary to continue the treatment.

In consumption these emulsions are valuable whenever an increase of food is indicated, as is practically always the case. The existence of fever, intestinal catarrh or a dyspepsia are not contra-indications.

Case VI.—A retired painter of sixty-five years had pursued his calling for a lifetime. Of late years he had recurring pulmonary hemorrhages and a chronic cough. He contracted a right-sided pleuropneumonia which ran a favorable course in seven days. Succeeding this came a mild attack of gout probably due to chronic lead-poisoning. He became exceedingly weak and wasted and a severe spell of hot weather in the first days of July resulted in heat prostration and a debilitating diarrhea. In June two attempts to give the milk of olive oil proved futile, because of the resultant brisk purgation. Cod-liver oil was then exhibited and he at once began to improve in every way. Body weight June 27th, 111 pounds; August 1st, 119½ pounds.

An increase in the body weight has been the usual result of the exhibition of artificial milks in most of the cases where they have been found useful. In treating leanness, pure and simple, as a fault of nutrition—a state of the human economy vastly more common in America than obesity—these emulsions yield good service.

Case VII.—A widow past the menopause, of consumptive parents, has for years enjoyed fair health. Her weight at its maximum was 145 to 150 pounds. Of late without patent cause she has been losing weight until on April 13, 1901, she had sunk to 127 pounds. She consented to take the olive-oil emulsion two or three times a day as an experiment with the following result: April 13, 127 pounds; April 20th, 131 pounds; April 27, 131 pounds; May 9, 133 pounds; May 22, 134 pounds; June 7, 136 pounds. Four pounds should be added to the last weighing for the difference in the clothing worn.

In typhoid fever such preparations may be used to an advantage as adjuncts to the milk diet, or as temporary substitutes for the same, or during the stage of recovery when solid food cannot be given with safety.

Case VIII.—A woman of sixty years developed typhoid fever after having been her son's sole nurse for the same disease. On the fifteenth day the temperature ranged from subnormal to normal without any further elevations. Convalescence was not accompanied by the usual signs of prolonged sleep and increasing strength, but, on the contrary, her state was one of collapse. She was restless; clear in mind; extremities cold and in a clammy sweat. The pulse extremely weak and irregular. She was nauseated and with difficulty retained the milk given her. Her condition was not due to intestinal hemorrhage, but from acute cardiac weakness. A liberal supply of liquid food was imperatively indicated and, as the exhibition of milk was an affair of much difficulty, its action was supplemented with four goblets of the artificial milk of olive oil a day. This was taken with relish and, at the end of twenty-four hours, with apparent very great benefit.

As a galactogue good and speedy results are achieved in that very large class of nursing women in whom a debilitated state of the system is the primary cause of scanty milk secretion. In another class where insufficient and improper food and minor dyspeptic disturbances are causative factors, results equally as satisfactory are obtainable from their exhibition. Any of the forms of the artificial milk may be prescribed, agreeable to the palate of the patient or the judgment of the medical advisor.

For the use of travellers, explorers and sportsmen, the milks are theoretically well adapted. Probably as an army ration or for sick and invalid soldiers they may be found serviceable. No data having been as yet formulated, these statements are merely offered in a suggestive way to any whose opportunities may hereafter allow a practical test.

The cases narrated outline the manner of using these artificial milks in daily practice. They have received a fair amount of local approval and have at times been adapted to family use. As they are extemporized emulsions; easily and quickly prepared; their ingredients inexpensive and common, they will be popular with the housekeeper, cook, or nurse. Finally, the process is devoid of technical detail and requires no apparatus or appliance that cannot be found in the humblest home.

ON THE BIOLOGICAL RELATIONSHIP OF PROTEIDS.[1]

(Preliminary communication.)

BY P. A. LEVENE,
OF NEW YORK.

I AM prompted to make this preliminary communication by the appearance of Uhlenhuth's article in the *Deutsche med. Woch.*, 1901, No. 45.

[1]From the Saranac Laboratory for the Study of Tuberculosis; Dr. E. L. Trudeau, Director.

Uhlenhuth finds that the serums of rabbits treated with blood of different animals form a precipitate on addition of muscle extracts of the respective animals.

All researches published previously to the last publication of Uhlenhuth lead to the belief that the serum of an animal that has received several peritoneal injections of a certain proteid acquired the property of forming a precipitate only on addition of a solution of the same proteid.

The new work of Uhlenhuth would indicate that there exists a biological similarity between the blood and the muscle proteids, or, in other words, a biological similarity between proteids having a different chemical individuality, but obtained from the same animal.

Our laboratory is now engaged in the investigation of this question, and, although the work is not completed, we wish to say that thus far our results seem to be in conformity with those of Uhlenhuth.

We have "immunized" rabbits for about two months with milk and found that their serums will form precipitates with milk, casein, milk albumin and also with beef serum. The same serum will fail to form precipitates with the entire white of the egg, egg albumin, egg globulin, chicken serum, sheep hemoglobin.

On the other hand, we found that animals that received injections of the white of the egg for two months will form precipitates with egg albumin, egg globulin, the yolk of the egg, with chicken serums, also with turkey serum.

No precipitate will be formed on the addition of milk proteids, beef serum, nor of the different proteids of the latter, of guinea-pig serum nor serum of a normal rabbit.

The results thus indicate that chemically different proteids derived from the same or closely related animals have the power of producing similar "precipitines" when injected into animals.

It therefore seems to us that human milk could be used for obtaining serum for the detection of human blood. The details of the work in progress will be published in full when completed.

MEDICAL PROGRESS.

THERAPEUTICS.

Regimen in Bright's Disease.—Without questioning the fundamental importance and value of absolute milk diet in Bright's disease, A. MARTINET (La Presse Méd., Nov. 13, 1901) observes that clinicians of wide experience have all seen patients do well in spite of the latter's refusal to submit to the dietary rules prescribed by their physicians. This writer recalls the contention of Robin, who believes that vegetarian diet is more potent than an exclusive milk diet in the control of albuminuria. The principle of dietary regimen in renal disease is the reduction of the work of the secreting cells. It is impossible to exclude nitrogen elimination absolutely, because, even in absolute starvation or a diet of water alone, proteid substances derived from the body tissues continue to find their way through the secreting renal cells. To maintain nitrogenous equilibrium at least three liters of milk a day must be taken, and, while some patients bear this diet well, it provokes in others gastric dilatation, fermentation, toxemia and loss of strength. When disturbances of digestion follow the tentative resort to milk diet, the latter may wisely be abandoned for a more liberal regimen; the general condition of the patient and not the quantity of albumin in the urine becomes the guide to treatment in such cases. In acute nephritis absolute milk diet may be regarded as essential; in chronic cases the following plan is proposed: Begin with milk exclusively, and watch the urine; usually the albumin will first increase, then diminish, then remain stationary; now add vegetables and study the albuminuria quantitatively as before; when variations cease try meats cautiously, again studying the albuminuric curve. Ultimately that diet is adopted which minimizes the albuminuria, whether it be purely lactic, lacto-vegetarian, or lacto-carno-vegetarian.

Sulphur in Dysentery.—Mr. Arbuthnot Lane advocates the use of sulphur in the treatment of anthrax, and, as ipecacuanha was also used in this disease, E. G. RICHMOND (Lancet, Nov. 23, 1901) determined to try it in cases of dysentery. Many cases of the latter disease failed most signally to respond to the ipecacuanha in the Imperial Yeomanry Hospital at Delfontein, South Africa, but where sulphur was used the results justified all the expectations hoped for. There was little or no tendency to relapse or to chronic conditions of alternating diarrhea and constipation. Every patient was ordered a farinaceous diet from the first; meat of every description was forbidden until the diarrhea had ceased for a week. Twenty grains of sublimed sulphur, combined with five grains of Dover's powder, were ordered every four hours, and from the administration of the first powder the general condition of the patient became much improved; the diarrhea and distressing tenesmus and griping were relieved at once, while the passage of blood and mucus was stopped in two days. The writer treated ten chronic and eleven acute cases of dysentery. In the first class sulphur alone was administered, but in the acute cases opium was added. Just how the sulphur acts the author does not state, but he thinks that there may be liberated sulphuretted hydrogen and other sulphur acids which inhibit the growth of the micro-organism specific for the disease.

Suprarenal Extract in Hemophilia.—According to Dr. F. Grunbaum, this condition is due to a congenital hyperplasia of the muscular coats of the arteries, and thus suprarenal extract should not have any effect upon it. However, W. THELWALL THOMAS (Brit. Med. Jour., Nov. 23, 1901) says that he has used the drug most extensively with absolute results. The powdered extract is put on the bleeding surface and five grains given internally every four hours. It is advised that "bleeders" should be given this drug, that they may carry it with them on all occasions and that they apply it themselves whenever the emergency shall arise. The writer is of the opinion that, in spite of the pathology of the disease, the drug should have a larger and more complete trial.

Should Fever Be Treated, and How?—An analysis of speculative arguments as to the treatment of fever is presented by E. JENDRASSIK (Revue de Méd., Nov. 10, 1901), who then proceeds to discuss the question clinically. Although those who oppose the treatment of fever maintain that mortality has not essentially changed since the introduction of antipyretics, statistics are not reliable and every clinical observer can recall cases of infectious fevers in which grave

conditions were distinctly ameliorated by antipyresis. Such cases are more numerous in pneumonia than in typhoid. Assuming that the chances of cure are not improved by the use of antipyretics, and that febrile diseases cannot be shortened by this means, Jendrássik remarks that it would be worth while still to remember the patient's comfort. The final issue of a case of pleurisy is not affected by suppressing the patient's cough, but pain is lessened. The author takes issue with those who decry the chemical antipyretics. He believes that baths are of precious tonic value in some cases, but that they cannot rival drugs as antipyretics. Chemical antipyretics are objected to on the ground that they lessen oxidation and hinder nutrition; but to diminish oxidation is to spare the patient's strength, while digestion certainly is not lessened by lowering a febrile temperature. Antipyrin does diminish the secretion and lessen the toxicity of the urine; nevertheless the augmentation of the cutaneous secretion and the eliminative power of the skin are entitled to consideration. The danger of collapse from the use of antipyretic drugs is constantly asserted; but few cases are reported, however. Jendrássik favors among antipyretic drugs, antipyrin, phenacetine, and in moderate fevers, aspirin. In grave fevers, especially in children, phenacetine is prefered; tolerance is easily acquired and may necessitate a change after a few days. The general indication for the use of antipyretics is the presence of a fever which the patient is bearing badly. In the case of very weak patients it may be wise to give a little alcohol or other stimulant at the moment when the drug begins to act.

Iodides and the Heart and Circulation.—When iodides are given for aneurism, arteriocapillary fibrosis and degenerative changes of the cardio-vascular system, no immediate action upon the circulation is observed as in the administration of nitrites, aconite and digitalis. Whatever curative effect they may exercise is brought about gradually and slowly, so that only after prolonged administration can any distinct improvement be seen in the morbid condition, say R. STOCKMAN and F. J. CHARTERIS (Brit. Med. Jour., Nov. 23, 1901). Rosenbach expresses the opinion that the iodides are of no value in the treatment of aneurism and that they are even hurtful in arteriosclerosis. As a rule, the pulse remains unchanged to the finger-tips after the administration of sodium or potassium iodide, both in rate and in force. In spite of this, text-books tell us that the iodides produce a depressing effect upon the circulation and blood-pressure. The writers believe that the laboratory results should not be taken too seriously, as they are deduced from observations lasting but two or three hours, whereas in disease one can study its effects for weeks and months. In conclusion the results obtained were as follows: Sodium and potassium iodide given by the mouth do not alter the dynamic conditions of the circulation. They neither weaken the heart directly nor dilate the arterioles. The therapeutic effects must be due to some other mode of action. It is sometimes observed, for instance, that iodides frequently quicken and weaken the pulse, especially in goiter. Sometimes their administration is followed by emaciation. There is good reason for believing that in neither case is this a direct effect, but is due to increased formation or alteration of the iodine-containing thyroid secretion which has a powerful action upon the circulation and on metabolism.

A New Treatment for Hay-Fever and Allied Nasal Affections.—Treatment in this condition has usually been directed toward a supposed pathological condition of the nasal mucosa or hypertrophy of the tubinate bones. More recently also remedies which affect the vasomotor system have been largely used. E. FINK (Deut. med. Woch., Nov. 14, 1901) contends that these measures have only a temporary effect, as they do not take into consideration the true source of the irritation and the consequent discharges. His observations confirm those of Helmholz and a few other observers that the secretions are derived not from the nasal cavity proper, but from the accessory sinuses, particularly, as he showed, from the antrum of Highmore. He therefore treats such cases by insufflation, introducing a proper catheter into the orifice at the center of the middle meatus and using aristol by preference. The improvement was marked in all cases, most after three applications, the more resistant ones after seven or eight. The characteristic symptoms lessen and the intervals between tne attacks are prolonged. It is very important to supplement the local measures by treatment directed against the accompanying neurasthenia.

Treatment of Leucorrhea and of Gonorrheal Vaginitis.—P. CHAPELLE (Journ. de Paris, Nov. 25, 1901) says that yeast in the treatment of chronic leucorrhea and vaginitis due to gonorrheal infection has recently been tried with considerable success. Dr. Landau of Berlin was the first to apply it locally by injection for troublesome vaginal secretions, and found that small quantities produced a rapid and complete arrest of the discharge after a few weeks. Murer in France has used it in the same manner in gonorrheal discharges from the vagina, and found yeast most effective in suppressing inflammation of the mucous membranes, which regained their normal color rapidly. In the gonorrhea of men, however, it was not uniformly successful. In leucorrhea and gonorrheal vaginitis there occurs a substitution of a morbid fermentation for a non-dangerous yeast fermentation, the yeast-cells (saccharomyces cerevisæ), appear to devour the morbid germs, which set up inflammatory conditions. Pure ferments like yeast attract pathogenic germs, allow themselves to be penetrated by them and, once enveloped, destroy them by a true phagocytosis. The application of yeast itself in this connection is not convenient, owing to its keeping badly, its offensive smell and the difficulty of obtaining fresh supplies, as well as its inconvenient frothy nature, which makes it difficult to be retained when injected. This, however, can be overcome by using a pure desiccated form, known as cerevisine, which may be exhibited in the form of a pessary and placed in position on going to bed, or a paste made up with glycerite of starch, and retained with a tampon of absorbent cotton, or again applied by dipping absorbent cotton in a thin paste of cerevisine and water. The quantity for application is not important, as it is perfectly harmless, but from one to two teaspoonfuls can usually be introduced and retained in the vagina during the night, which will give more cleanly and comfortable results than injections of brewer's yeast during the day.

Effects of Electrical Currents and the Roentgen Rays on Bacteria.—After numerous experiments made with the direct, alternating, and Tesla currents, and also with the X-ray, the following conclusions as to their influence on bacterial growth are noted by F. R. ZEIT (Jour. Amer. Med. Assoc., Nov. 30, 1901). The continuous electrical current alone has no bactericidal or antiseptic properties, but can destroy bacteria only by its physical effects, heat, or chemical effects, the production of a bactericidal substance by electrolysis. A magnetic field has no effect whatever. Alternating currents favor growth and pigment-production. Tesla currents, those of high potential and frequency, are only effective from the brush discharges by the pro-

duction of ozone. The Röntgen rays have no direct bactericidal properties.

Mercury and the Buccal Mucosa.—The condition known as mercurial stomatitis which sometimes appears early in the treatment of syphilis is, according to DR. SUBIRANO (Rev. Esp. de Sifilografia y Dermatologia, Oct., 1901), a septic infection due to disturbance of the physiological equilibrium normally existing in the mouth between the saliva and lymphatics, on the one hand, and the bacteria upon the other. Mercury, through its elimination by the bucco-salivary glands, changes the chemical nature of the saliva and renders the mucosa a fitting soil for increased activity of bacteria. As the number of bacteria in the mouth depends largely upon the condition of the teeth, Dr. Subirano holds that the first duty of the physician to his luetic patient is to obtain the coöperation of his dentist before and during mercurial treatment in order that the mouth may be rendered as nearly as possible aseptic; lest the appearance of stomatitis, so common among those who neglect the mouth's hygiene, lead to the belief that mercurial saturation has been reached and to the too early withdrawal of the drug, thus imperiling the vital organs through the influence of the syphilitic virus.

Intra-Arachnoid Injections of Antiseptics.—The possibility of a new therapeutic agent for cerebro-spinal infections is suggested by the experiments of A. MARIOTTI (La Riforma Medica, Oct. 3, 1901) in the injection of antiseptic substances in dogs by lumbar puncture. The solutions used were carbolic acid, iodine, and corrosive sublimate in quantity sufficient to destroy micro-organisms without producing toxic effects in the subject treated, the amount being about equal to the hypodermic dose. Unfavorable symptoms were not observed in any of the dogs experimented upon, even after repeated injections. With the view of ascertaining how high the fluid was carried, a colored solution was injected and after two hours the dog was killed; examination showed that coloration extended as high as the fourth cervical vertebra. Other experimenters have reported coloration extending to the brain after lumbar injection.

Quinine as Styptic and Antiseptic.—Iodoform and its derivatives have so many objections that H. MARX (Centralbl. f. Chir., Nov. 9, 1901) has been induced to search for substitutes. Among these he tried quinine with very great satisfaction. He makes a solution containing hydrochlorate of quinine one, alcohol three, and distilled water to one hundred parts. The quinine may be increased to two or more per cent. As a styptic he finds that gauze soaked in one of the above solutions is without equal, especially in bleeding from the parenchyma of organs like the liver. As a disinfectant, he has tried it only upon infected wounds and sinuses. Here it is active, efficient and certain. He also has found the above solutions a convenient means of freeing the hands from infected matter during an operation. He is now experimenting with various processes for producing gauze impregnated with quinine in the same manner as we now impregnate it with iodoform. The results of these experiments he promises to publish at a near date.

SURGERY.

Some Experiences with Blood-Examinations in Surgery.—Some surgeons refuse to operate on a case in which hemoglobin is reduced below 40 per cent. J. B. DEAVER and E. K. MOORE (Phila. Med. Jour., Nov. 23, 1901) state that in the German Hospital of Philadelphia operations have been successfully carried out for acute suppurative conditions or after acute or chronic hemorrhages notwithstanding the most extreme oligochromenia; several cases showing less than 20 per cent. of hemoglobin. The erythrocyte-count gives the surgeon an index of the powers of resistance of a patient as well as a guide on the severity of the infection. In appendicitis leucocyte-counts ranging from 10,000 to 17,000 cannot be relied upon to reflect the character of the local lesion, since this degree of increase may be found in mild catarrhal and in purulent cases. Counts of over 20,000 invariably indicate pus, gangrene or general peritonitis. In the differential diagnosis of appendicitis the leucocyte-count is of limited value, because ovarian abscess, pyosalpinx, renal abscess, hepatic abscess, gall-bladder empyema, and malignant disease of the cecum are all as a rule accompanied by leucocytosis. Acute gastritis and dysmenorrhea may or may not present a high leucocyte-count. In the diagnosis between appendicitis and uncomplicated typhoid, leucocytosis suggests the former. In carcinoma the blood changes are not pathognomonic. The recently-proposed theory that an increase in polymorphonuclear leucocytes shows the presence of pus without an absolute increase in leucocytes is not yet proven.

New Method for Sterilizing Catgut.—The following method is advised by C. A. BALL (Brit. Med. Jour., Nov. 16, 1901). Catgut up to No. 4 is rolled on glass reels and soaked for twenty-four hours in a 5-per-cent. solution of formalin; it is then thoroughly washed in cold water. It is next dropped into boiling water and left there for from five to ten minutes, according to the thickness of the gut. Finally, it is placed in the following solution: Mercury perchloride, 1 part; boiled glycerine, 250 parts; methylated spirit, 1,000 parts. The gut is then ready and receives no handling after sterilization until it is used. The glycerine and spirit dehydrate the gut and the former renders it pliable. The mercury perchloride impregnates the gut swollen by boiling with an antiseptic and hardens it sufficiently to prevent its twisting when moistened by the tissues during the process of stitching, a difficulty with gut dehydrated by alcohol alone. Catgut prepared in this way is undiminished in strength and keeps well; it is pliable and knots nicely; it is absorbable (No. 0 is absorbed in about six days); and, lastly, it is sterile.

Cholecystitis and Cholangitis Complicating Gall-Stones.—A contribution to the surgical pathology of this subject is made by D. N. EISENDRATH (Jour. Amer. Med. Assoc., Nov. 30, 1901), in discussing the case of a girl aged seventeen, who was operated on for gall-stones and purulent cholecystitis in which the colon bacilli were found in pure culture, and who died three days after the operation with symptoms of cholemia, whose liver showed evidence of a diffuse hepatitis and non-suppurative cholangitis, which undoubtedly disturbed the hepatic function to such an extent as to cause death. The question arises, Why should a patient die with symptoms of cholemia whose only complaint had been gall-stones complicated by a purulent cholecystitis? Although normal bile is sterile and a poor culture medium, it has been found that anything which interferes with the contractility of the gall-bladder musculature, the presence of a foreign body, or obstruction of the common duct, causes a marked increase in the number of micro-organisms in the biliary passages. Such infection is also known to be of prime importance in the formation of gall-stones. The latter often cause stagnation of bile, thus favoring the invasion of the liver parenchyma itself, usually by the colon or typhoid bacillus, and inducing necrosis. This results in paralyzing the ability of the liver-cells to get rid of bacteria and various toxins and also in reducing to

a minimum the formation of urea and allied products. The death of the patient in question was probably due therefore to an auto-intoxication, resulting from a lack of functional activity of the liver-cells and hepatargy would be a more suitable name than cholemia. The symptoms are mostly of a nervous character and greatly resemble uremia or diabetic coma. In every case of gall-stones an exact diagnosis must in addition be made of any complicating conditions. With pus present in the gall-bladder operative interference should be early and the prognosis guarded on account of the possible cholangitis.

Treatment of Piles by Injection of Carbolic Acid.—In applying this treatment attention should be paid to the variety of hemorrhoids, the strength of the solution, the amount used at each treatment. G. W. GAY (Boston Med. & Surg. Jour., Dec. 5, 1901) describes the carbolic treatment as palliative merely and as applicable only to internal piles. It is safe, not painful, can be done in the physician's office, requires no anesthetic, does not compel the patient to go to bed. Bleeding is controlled, protrusion prevented and the tumors so shrivelled up that for a long time they give no discomfort. External piles are made worse by this treatment. In treating piles which are above the internal sphincter or which will remain there when so placed, a 10 per cent. carbolic acid solution is used, the dilution being with glycerine and water. For a pile as large as a filbert, one minim of the solution will suffice; for larger ones two minims are required. An ordinary hypodermic needle is used.

Early Diagnosis of Hip-Joint Disease.—Diminished abduction is universally recognized as a diagnostic point in advanced stages of hip-jonit disease. It is maintained by J. A. BECHER (Berl. kl. Woch., Nov. 25, 1901) that this same test can be utilized advantageously in the diagnosis of the early stages of the disease, long before palpation reveals changes in the joint and before any deformity whatever in the trochanteric region can be demonstrated. This symptom is of value in the differential diagnosis of arthritis deformans coxa, and sciatica. The patient is asked to spread his legs as far apart as possible, when it becomes evident at once that on the healthy side there is a sharper angle between the extremity and the trunk than exists on the opposite side.

Umbilical Hernia.—A new procedure for the radical cure of umbilical hernia is proposed by H. B. DELATOUR (Brooklyn Med. Jour., Dec., 1901) which may be briefly described as follows: An elliptical incision is made about the base of the tumor through the skin and subcutaneous tissues, and the sac freed from the ring. A median incision is made in the abdominal wall about one inch below the edge of the ring and the peritoneum opened. The finger is introduced and swept around the ring within the abdomen, and all adhesions broken up. The incision is carried up on either side of the fibrous ring to a point in the median line an inch or so above the upper limit of the ring. This removes the sac unopened. The hardened neck may then be incised and the contents examined. The omentum and intestines can be treated as required. The abdominal wound should be closed as follows: The peritoneum and the posterior sheath of the rectus should be sewn with a continuous catgut suture, next the edges of the rectus, then the anterior sheath with chromic gut and the skin with subcuticular suture of silk. These advantages are claimed: (1) A saving of time and minimum handling of tissues; (2) it takes away from the abdominal cavity the contents of the sac until they have been inspected so that gangrenous intestines or omentum are not necessarily handled; (3) it gives firm closure of the wound with proper approximation of the layers.

Compound Fracture of Both Jaws.—This rare occurrence is described by H. WEIGHTON (Lancet, Oct. 26, 1901). The injury was received in a coasting accident on a bicycle, by being thrown against a stone pillar. Although there was no external wound, the lower jaw was found to be broken near the symphysis and part of the alveolar margin with three teeth was detached. There was likewise a fracture in the upper jaw on each side in the region of the canine teeth, but without much displacement or deformity. The whole premaxillary bone could be easily moved about. The primary, temporary treatment was with wire splints fixed on the outside with a poroplastic splint fitted to the chin and fastened with a four-tail bandage. The next day a dentist made a mould for both jaws by means of which all the teeth were brought into line and held there. The outer dressing was then replaced. A dilute solution of permanganate of potash kept the mouth clean. Fluid diet was administered through the nasal tube. After a short time drinking through the mouth was permitted. After five weeks the cure was found complete except the broken alveolar margin, which had to be removed. At the present time the patient can eat all kinds of food and has no deformity.

Pelvic Suppuration.—The appearance of pus in the pelvis is always serious. From the nature of anatomical arrangement of the genito-urinary tract, it is more common in the female than in the male. J. L. FAURE (La Gynecol., Oct. 15, 1901) gives the following headings for its medical treatment. The basis is absolute rest in bed, begun as soon as the active symptoms appear and continued until they disappear. It is surprising how much can be accomplished by this means alone. Very hot vaginal irrigations are the next most important therapeutic measure. They act by quieting the congestion of the uterus and its adnexa, and by promoting a resorption of the exudates. An antiseptic, such as the bichloride of mercury, may be added with the sole purpose of keeping the vagina perfectly clean. It is, of course, impossible for such medicament to reach the cavity of the uterus or the adjoining tissues. Rectal irrigations of hot water may be considered more efficacious than the vaginal injections, because with the necessary precautions they come into nearer relation with the tubes, ovaries, and broad ligaments than they. A double-current rectal tube is essential for their successful use. The temperature must be as high as can possibly be borne. After the acute symptoms have by these means subsided, gynecological massage must be tried. In order to be adequate this must be carried out regularly and thoroughly. Mineral waters and thermal baths are not to be forgotten. The other systemic means of supporting the patient are too familiar to need mention. These measures, with the addition of opium suppositories, mustard plasters and ice upon the lower half of the abdomen, will control or cure a very great number of cases, and prevent surgical treatment, which, after all, should be the last resort.

Congenital Dislocation of the Hip.—Much attention has recently been given in the European press to this subject. DR. JOACHIMSTAHL (Arch. f. klin. Chir., 1901, B. 65, H. 1) gives the following points in the pathology of this condition. The acetabulum is smaller and flatter than normal, as a rule, but occasionally deeper and almost conical. Instead of its normal shape, it may be practically a pyramid of three sides. Its actual diameters are not, however, much reduced. Its deepest part is thicker than normal and the bone is filled with holes for nutrient vessels. The pelvis as a whole near the acetabulum is considerably thickened. The ilium

shows just above it, in most subjects, the socket of the false joint created by the pressure of the femoral head. Below the anterior inferior spine is a very deep notch, which accommodates the ileopsoas muscle as it passes upward to reach the lesser trochanter in its new position. The ilium is also directed more to the front, probably through pressure by the dislocated femur. The pubic angle is smaller. The tuberosities of the ischia are everted. The foramen obturatorium is smaller. The rami of the pubis and ischium are changed in direction. On account of the tilting of the pelvis downward on the side of the dislocation, there is a compensating scoliosis in the lumbar vertebræ. There are similarly-profound changes in the thigh bone. The head is either pointed or flat; the neck is shorter and more nearly at a right angle with the shaft. The upper extremity is twisted backward on the axis of the shaft, so that it presents a peculiar comparison with the normal side. Notwithstanding these profound changes in the old cases, he finds that in the recent cases, namely, children five years old or younger, treatment produces marked improvement. This consists in general anesthesia, fixation of the pelvis by an assistant, steady traction downward, usually with the aid of apparatus for ten minutes to overtire the muscles. Flexion and abduction are then carried out to such an angle that the head is felt or heard to snap back into the acetabulum. Pressure by an assistant upon the great trochanter is a valuable aid at this point. The angle to which flexion and abduction must be carried is usually about ninety degrees. Rotation inward or outward is often not necessary. After the head has slipped into place, the limb is held in the position at which this occurred and a plaster-of-Paris bandage is applied enveloping the whole of the thigh, the pelvis and the trunk just above it. While this is drying, pressure is made over the great trochanter to provide against recurrence of the dislocation. When the splints have hardened the relations within the joint are made out with the X-ray. This fixation dressing is kept on for three months or more. Then it is taken off and the patient allowed to get up on crutches. As he goes about the weight of the limb gradually restores it to its normal position, and then, with the aid of massage and passive and active motion, the child emerges with a hip that is almost normal in appearance and perfectly so in function.

MEDICINE.

Cryoscopy of the Blood for Prognosis.—Of late this procedure has come into vogue upon the Continent. Van t'Hoff and Raoult pointed out that fluids freeze at a lower point in proportion to the quantities they contain of impurities dissolved in them. Korányi, applying the law to blood and urine, showed that normal blood possesses a fixed freezing point of 0.56° C. below that of distilled water which forms the zero of that thermometrical scale. From this point it does not vary more than by one-hundredth of a degree up or down. Various German and French writers have applied Korányi's observations to the study of abnormal blood. According to ALEXANDER OGSTON (Lancet, Nov. 9, 1901) their conclusions may be thus briefly stated. So long as the blood is healthy and has its effete constitutents adequately eliminated, it retains its normal freezing-point, *viz.*, 0.56° C., or varying between 55°-57° C.; but if the elimination becomes defective, the freezing-point sinks to 0.58°-0.60° C. or even in one case of Kümmell's to 0.71° C. Beckmann has devised an apparatus for determining the freezing-point of blood and other secretions. It consists of a large test-tube set into a vessel containing ice and salt. Through a perforated cork placed in the mouth of the first test-tube, a second and smaller test-tube is inserted. This leaves an air space between the two tubes. The fluid to be frozen is put in the inner tube. A special thermometer is used which has as zero the freezing-point of distilled water. The freezing-point of the blood is to be determined by specialized manipulations with this thermometer. A case of fibrosarcoma of the kidney showed a rise in freezing-point. One case of cancer of the cecum showed a rise of .07 of a degree. The blood of a patient with an old empyema showed a fall of .01. Another with cystitis had a lowered freezing-point of .05. Phlegmasia dolens gave a drop of .03.

Spasmodic Bronchostenosis.—This affection is practically nought else but asthma without paroxysms and is caused by a tonic contraction of the muscular walls of the bronchi. As in true nervous asthma, a nervous element is the most prominent feature of bronchial spasm, other changes being either secondary or absent. A. ABRAMS (Med. Rec., Dec. 7, 1901) says that in bronchospasm, associated with bronchitis, as it usually is, we have all the symptoms of the latter plus a spasmodic cough which is exceedingly distressing and usually resists ordinary treatment. Sonorous expiratory râles with prolonged and accentuated expiration characterize this condition. Expectoration always signifying a suspension of the bronchial spasm. Amyl nitrite may be used in diagnosis, for it will always temporarily relieve such a spasm of the bronchi. Climatic changes are almost as essential as in ordinary asthma, but the iodide of potassium is frequently found to be a most effective remedy. A useful prescription is:

℞ Iodide potass.....ʒv
Tinct lobeliæ.....ʒx
Sp. glonoini.....mxvj
Elix. bromidi potass.....ʒiv

M. et. Sig. One teaspoonful three times a day, after meals.

Splenic Anemia with Ascites (Banti's Disease).—A form of disease characterized by anemia, marked enlargement of the spleen and later cirrhosis of the liver with ascites, was first described in 1894 by Banti. H. SENATOR (Berl. klin. Woch., Nov. 18, 1901), in analyzing a series of cases corresponding to those reported by Banti, shows that the stage of splenomegaly and anemia lasts for three or more years, in some instances having a duration of eleven years. Ascites then gradually supervenes, the symptoms of anemia meantime becoming aggravated. The stage of ascites terminates fatally after from five to seven months. Earlier writers regarded cases which were seen for the first time in the stage of ascites as hepatic cirrhosis; but the clinical forms never fully corresponded to any of the known varieties of cirrhosis of the liver, being always distinguished by extraordinary splenic enlargement and by hemorrhagic tendency. Senator maintains that the clinical course of Banti's disease is such that the splenomegaly cannot be attributed to portal obstruction. He is unable to prove that the disease is of infectious origin after careful search for a cause. The theory of infection from the intestinal canal is supported by the frequency of a preliminary history of diarrhea and other intestinal disturbance. The possibility that the ascites in these cases may sometimes be due to factors other than hepatic cirrhosis is suggested by the disappearance of this symptom in a case which Senator employed good nourishment, iron and arsenic; the splenic tumor and the anemia remained. The hemorrhagic tendency and especially the liability to hematemesis have been insufficiently emphasized by previous writers. Icterus is an inconstant symptom, even in advanced cases. Urinalysis fails to show any marked abnormality; the urine

contains no bilirubin or urobilin; albumin is rarely present. The blood characteristics are as follows: A variable diminution of erythrocytes, a relatively great loss of hemoglobin (low color-index), an absolute and relative loss of leucocytes without any change in the proportions of the different types of white blood-cells. A mild grade of fever is oftener absent than present. The first stage of Banti's disease cannot be distinguished from simple splenic anemia. The most recent report on the extirpation of the spleen in the cases is that of Maragliano, who reports nine recoveries out of eleven operations, the two remaining cases having been lost through uncontrollable hemorrhage. Aside from splenectomy treatment is limited to iron and arsenic, hygiene and diet.

Enterospasm.—Through a series of investigations in the intestinal neuroses and through observation of clinical cases, ABORTI (Rendiconti della Associazione Medico-Chirurgica di Parma, Nov., 1901), has collected the following data concerning the comparatively unknown and frequently unrecognized condition of enterospasm. This is understood to be a spastic state of the intestine, due to simultaneous contraction of the longitudinal and circular fibers. The condition may be caused (1) by anything intrinsic or extrinsic, which excites the peripheral nerves of the intestine; as inflammations, ulcerations, or irritation from other organs whose sympathetic ganglia are connected with the intestines; (2) by anything exciting the nerves which govern intestinal movements, or paralyzing the inhibitory nerves; (3) or it may be the manifestation of a general neurosis; hence hysteria and neurasthenia are common causes of the affection. The spasm may be general, although rarely so in the nervous form, or limited to one or two points; the colon being the most frequent site. In the first case, we have the characteristic retraction of the abdomen in boat-shape; in the latter, the abdomen assumes an irregular outline due to tumors corresponding to intestinal dilation above the site of the spasm. The sprincipal symptoms are (1) obstinate constipation with consequent loss of appetite and weakness; (2) slight abdominal pain located about the umbilicus, if the colon is the site of the spasm; (3) borborigmus; (4) tympanites; (5) tumefaction of the abdomen; and (6) more or less characteristic feces, the stools being small, usually cylindrical, and sometimes as narrow as a pencil. The prognosis depends upon the degree of spasmodic contraction and the possibility of removing its cause. The condition may persist, causing such changes in the tissues as to constitute a veritable stricture; or may disappear in a moment, as in hysterical cases. That occlusion of purely nervous origin occurs is proven by the cases which come to operation, in which no lesion can be discovered. The diagnosis is to be made from the symptoms mentioned, but above all by the careful analysis of the patient's general and nervous condition. In the case of rectal spasm the diagnosis must rest largely upon the last named considerations, and upon the effect of treatment. Massage, faradization, and drastic purges all increase the spasm. The main reliance in treatment is to be placed upon care of the general health, and such remedies as bromides, belladonna, and even opium if necessary.

Supra-Orbital Reflex in Facial Paralysis.—A reflex recently described by D. J. McCarthy consists of a distinct, but slight contraction of the orbicularis palpebrarum when the supra-orbital nerve, or occasionally one of its branches, is struck a slight blow. McCarthy regards this reflex as a demonstration of the sensori-motor mechanism of reflex action, inasmuch as irritation of a purely sensory nerve produces contraction in a muscle not immediately in relation with it, and supplied by a purely motor nerve. From a study of this reflex in cases of unilateral facial paralysis, J. SAILER (Phila. Med. Jour., Nov. 23, 1901) concludes that it is a true sensori-motor reflex. Contraction as a result of direct irritation of fibers of the orbicularis extending above the eyebrow can be excluded. Irritation of the supra-orbital nerve of one side may produce contraction of the muscles of the opposite side. In some cases the reflex manifestation may extend to other muscles which are situated a considerable distance from the supra-orbital nerve.

PATHOLOGY AND BACTERIOLOGY.

The Cause of Cancer.—Unmistakable proof of the presence of parasites as a cause of malignant disease is by no means at hand and we are still groping about, but undoubtedly nearer the light which is sure to come from future investigation. G. R. WILSON (Med. Times, Nov., 1901) reviews the experimental work upon this subject. As long as 1840 Langenbeck injected a dog with carcinomatous tissue and the dog subsequently developed carcinoma. Numerous similar experiments have since been made, but much of the work has been discredited. The bodies called parasites are generally found in the epithelial cells, especially in the protoplasm about the nucleus. They are spherical, frequently seeming to be surrounded by a double capsule. The opponents of the parasitic theory say that no one has yet been able to grow them outside of this environment. When injected alone they do not reproduce themselves in that animal. McFarland believes that these bodies are simply digested leucocytes, the result of hyaline degeneration, or vacuoles. Even if these parasites are present, are they really the cause of cancer? Cancer probably cannot be transmitted from one person to another. It is a non-inflammatory disease, while all known infectious diseases, except malaria, are inflammatory. The study of experimental teratology, the subject of malformations in the fetus and child, may some day be able to furnish valuable information.

A Modification of Neisser's Test for Diphtheria Bacilli.—Since the beginning of this year, in Cambridge and Colchester, England, over 2,400 tests for the Klebs-Loeffler bacillus have been made from cultures taken from the throats of persons suffering from diphtheria and from the mouths of those who have been in contact with such cases. In all of these cases the following modification of Neisser's stain has been employed at the recommendation of L. CORBETT (Lancet, Nov. 23, 1891). One drop of 5-per-cent. acetic acid is applied to the edge of a cover-slip preparation and drawn under it by means of a piece of filter paper held at the opposite side. The preparation is previously stained with a dilute solution of methylene blue. If the bacilli are watched while the acid is entering under the cover-slip, one sees first a current of fluid sweeping up the loose bacilli and hurrying them away. A blue cloud next appears and blots out everything for a second and passes on. Then once again the field is bright and clear, and the diphtheria bacilli, if such they are, show the characteristic polar bodies if stained in the way Neisser recommended—only the bodies of the bacilli are not brown, but pale blue. Hoffman's bacilli have a fairly-characteristic appearance when treated in this way. They do not so easily decolorize as the diphtheria bacillus and at about the middle of each half some blue remains. With the diphtheria bacilli the change is instantaneous, and the picture revealed is often not inferior to that of a Neisser specimen stained in the usual way. Neisser's stain fails to show the polar bodies in a small proportion of true bacilli; and it shows minute and doubtful ones in a few of Hoffman's pseudodiphtheria bacilli.

Agglutination Reaction in Different Grades of Infection.—Although five years have elapsed since Widal first published his method for the serum diagnosis of typhoid fever many points in the application of this method still remain obscure. While it is generally admitted that the reaction is one of the factors concerned in the resistance of the body to infection, it has not been definitely determined whether the intensity of the reaction corresponds closely to the ability of the body to resist infection. S. J. GOLDBERG (Ctlblt. f. Bak., Nov. 7, 1901) has taken up this question experimentally. The micro-organisms employed in his work were the b. pyocyaneous and the b. typhosus. In different series of experiments rabbits and guinea pigs were inoculated with fatal and non-fatal doses of these organisms or their toxins. The serum of these animals was then after varying periods of time tested for its agglutinating power. In order to control the results the serum of the animals used was tested previous to the inoculation for its normal agglutinating power. His work shows that in fatal infections the agglutination reaction remains the same as before the infections. In non-fatal infections the agglutinating power of the blood is increased over the normal. Different animals, however, inoculated with the same dose of bacteria or toxins do not show an equal increase of agglutinating power. With increasing infection the agglutinating power of the serum gradually increases until a maximum is reached; it then gradually subsides to the normal. In typhoid and pyocyaneous infections the degree of agglutinating power is not proportional to the degree of immunity produced. Agglutination is to be considered as a protective reaction of the organism against infection.

Diazo-Reaction in Malaria.—Much has been written concerning the presence of the so-called diazo-reaction of the urine in various forms of malaria and its value as a means of diagnosis between this disease and typhoid fever. In this connection the recent observations of J. BRAULT (Comptes Soc. Biol., Nov. 8, 1901) are of interest. He studied the disease during the recent epidemic in Algiers. In judging the results of the reaction not only was notice taken of the color of the body of the liquid, but especial attention was given to the coloration of the foam produced by violent agitation. He reports seventy examinations of forty-four consecutive cases. The observations were made both before and after the crisis of the disease. Of these examinations forty-seven gave negative results, fifteen were doubtful, seven were slightly positive, and one gave a reaction of fair intensity. He believes that this method rarely fails to give a differentation between malaria and typhoid and is of value when bacteriological methods are inaccessible or fail.

Staphylococcus Pyemia.—Much confusion has existed in the conception of the various forms of local and general infection produced by the staphylococcus. G. MUSCATELO and J. OTTAVIANO (Virchow's Archiv, B. 166, H. 2) have taken up this subject and worked it out along experimental lines. The chief forms under which a general infection produced by the staphylococcus can appear, toxemia, toxemia with bacteriemia and pyemia, are intimately related with each other. The predomination of one or the other of these forms in general infection depends upon the grade and species of virulence of the infecting organism, the existence or non-existence of local predisposing conditions, the absorbing power of the affected region of the body, and the general or local natural immunity of the infected individual. In all forms of general infection produced by this micro-organism intoxication is the original and constant effect produced. It is the primary cause of the changes produced in the various organs and prepares the tissues for metastic bacterial localization. The primary changes in the organs by this intoxication lower the natural degree of immunity and produce abnormal local physical conditions which favor the formation of metastases. For the production of staphylococcus pyemia are necessary intense intoxication, localities of diminished resistance and the introduction of numerous cocci into the blood. The distribution of the metastic formations stands in direct relation to the local physical conditions of diminished resistance.

Origin of Blood Platelets.—Much speculation has been indulged in with respect to the origin of the so-called blood platelets. HANS HIRSCHFELD (Virchow's Archiv, B. 166, H. 2) has made an extensive histological study of the blood in order to ascertain the origin of these bodies. He employed Ehrlich's method, all the blood-smears being fixed by heat at 110° C. for five minutes. The blood plates undoubtedly arise from the red blood-cells, but only a limited number of these cells give rise to the formation of such plates. They are formed in the interior of the erythrocytes where they exist as endoglobular bodies. Several plates may be present in a single cell. They generally leave the cell through a single opening in the cell membrane. Occasionally several such openings are present. Similar plates may arise from the leucocytes, but this rarely occurs under normal conditions. It is, however, of frequent occurrence in leucemia.

Blood-Examinations in Malaria.—It is a common impression that in malaria the examination of the blood for the presence of the parasite is uniformly attended by successful results. Those who have had much experience in this work, however, well know that such is not the case. In this connection the results obtained by J. BRAULT (Comptes Soc. Biol., Nov. 8, 1901) in the examination of malarial blood are of interest. He stained his smears with eosin (1 to 1,000) and Borrel blue. Of thirty-five cases examined only sixteen gave positive results. Crescents were found once, crescents and ameboid bodies once and the spherical bodies fourteen times. All of the pernicious cases gave positive results. Of six quotidian cases three gave positive results. In only one out of five tertian cases was the parasite found. Chronic cases with a relapse never gave positive results. In discussing the results obtained by this observer, M. Laveran drew attention to the marked difference between these results and those obtained by other investigators and called into question the technique employed by Brault.

Infectious Nephritis of Pyelonephritic Origin.—Infectious nephritis produced by the ascent of micro-organisms from the urinary passages is of interest not only on account of the kidney lesions produced, but also because of the liability of a general infection arisings therefrom. OTTO BRUCAUFF (Virchow's Archiv, B. 166, H. 2) has recently examined sixteen cases of this disease. In the vast majority of cases staphylococci or colon bacilli are the causative agents. The lesions produced by these organisms are not capable of sharp differentiation. In five of the cases examined regenerative changes in certain of the kidney abscesses were in progress. In these regenerating areas the infecting bacteria could be demonstrated by microscopical examination. They were incapable, however, of artificial cultivation and hence had perished. It is impossible to say whether the tubules of the kidney are ever reformed as the result of the regenerative process. It is uncertain whether the results of these observations can be applied to kidney abscesses produced by the hematogenic properties of the staphylococcus or bacillus coli communis.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

SMITH ELY JELLIFFE, A.M., M.D., Ph.D., Editor,
No. 111 FIFTH AVENUE, NEW YORK.

Subscription Price, including postage in U. S. and Canada

PER ANNUM IN ADVANCE	$4.00
SINGLE COPIES	.10
WITH THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, PER ANNUM	7.50

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

SATURDAY, DECEMBER 21, 1901.

THE MEDICAL NEWS FOR 1902.

THE ideal medical journal is one that stimulates a man to put forth his best efforts in behalf of his patients, his profession and himself. It is one that gives him food for thought, one that contains news, facts and well-digested ideas, presented in the most practical and useful form, printed in the cleanest and simplest way.

The editor and publisher of the MEDICAL NEWS have aimed to produce the ideal weekly journal for the modern man of medicine. Only the original articles of men of authority and experience are accepted. It contains all the news of the medical week, not the news of gossip but the news of discovery, achievement and progress. The minor details of journal-making have been carefully studied, the choice of type, the width of margin, the quality of paper, the size of column and the grouping of subjects. The reader of the MEDICAL NEWS is freed from the weariness that comes from the use of fine type on thin paper, or the irritation of holding open a journal that persistently reverts to the folds of the mail, the friction that arises from looking up journal references with inconspicuous dates and poor indices.

The form in which we present this week's issue is that adopted for the coming year. By an increase of eight pages and a rearrangement of typography, space is provided for fully fifty per cent. more matter, and through judicious editorial management the exertion required of our readers will be so minimized that they may almost at a glance acquaint themselves with the best that is current in the medicine of to-day throughout the entire world.

We have planned for the coming year a series of papers in groups forming symposia on certain diseases. By concentrating in a single issue the discussion of a certain disease and presenting it from its many sides, we shall bring together the freshest experiences of the men most competent to handle the subject. The series of historical sketches of our principal medical schools will be continued, our correspondents in foreign medical centers will keep our readers thoroughly posted on European interests and the reports of home societies will be complete and recent.

The MEDICAL NEWS enters its sixtieth year with larger and fuller powers to maintain its allegiance to the aims and ideals of medicine and of the American medical profession.

REFORM.

THE medical profession of the city of New York has grown a trifle pessimistic on the question of the public care of the public health. It has become so accustomed to the presence of private greed and corruption in the distribution of city offices that the announcement of appointments made by the Mayor-Elect of able, scientific, and distinguished men as heads of the Departments of Health, Street Cleaning and Charities comes as an earnest of a new era of moral and material cleanliness.

We most heartily commend the good sense shown by Mr. Low; for he has surpassed even the fondest hopes of the profession. It was for a moment something of a disappointment to learn that a layman, although a man of science, and one unusually well fitted to cope with general sanitary problems, was to fill the very practical position of Health Commissioner, but, when Mr. Low announced that the Department was to be reorganized with Dr. Hermann M. Biggs in charge of the medical work, feelings of regret gave way to those of satisfaction at this eminently satisfactory arrangement.

The appointment of Dr. Biggs in connection with Dr. Lederle, shows that Mr. Low has appreciated as fully as the physicians of the city

the necessity of submitting all matters pertaining to the prevention of disease to a practising physician.

The city is still under further obligation to its new chief executive officer for his appointment of Dr. John McGaw Woodbury as Street-Cleaning Commissioner. Dr. Woodbury has shown great executive ability in a large practical experience in superintending the cleaning of camps and cities during the past Spanish campaign. Moreover, he has made a wide and deep study of sanitary methods and, being a physician, we can look for more than the much-needed but unusual coöperation between the Departments of Health and of Street Cleaning.

The profession of New York can now anticipate a comprehensive effort looking to a better condition of health in this community. With a united Health and Street-Cleaning Department, a competent and able Charities Commissioner and the strong probability of excellent nominees on the new board of Trustees of Bellevue Hospital, our ideal of perfection seems about to be realized.

VENEREAL DISEASE AND PUBLIC HEALTH.

As we begin the new century the watchword is the prevention of disease. Up to the present time, by a curious apparent contradiction, it has been mainly the medical profession who have been actively interested in the prevention of disease. Their livelihood depends on the treatment of disease, but they have devoted themselves to lessening their own pecuniary opportunities. Now, however, at length, philanthropists of all classes, have come to realize how much human happiness is bound up with the health of the human race.

Only one class of diseases has been kept beyond the pale of philanthropic advance. Poor sufferers from venereal disease are supposed to be outside the circle of those who deserve help, and the whole question of the correction of the evils, physical as well as moral, that result from venereal disease has been thrown upon the medical profession.

The report of the Committee of Seven appointed by the New York County Medical Society to investigate these evils, which we publish in full in this issue, shows how well the medical profession has realized its duty in this matter and how temperately helpful their suggestions may prove if followed in the true humanitarian spirit in which they are made.

While we are arousing the public to protect itself against consumption and the infectious diseases generally; while an expensive campaign is rightly waged against smallpox, and children are at last being rationally guarded from the ordinary diseases of childhood, it must not be forgotten that we have always with us disease enemies that are much more serious in their ravages than any of these.

This the public refuses to realize. The present report can accomplish no greater good than by bringing the subject of venereal diseases and their consequences into prominence and thus serving to dispel some of the obscurity in which it is deliberately allowed to remain. We have reached a stage of culture beyond that in which ignorance is reckoned as innocence. Assumed ignorance is never more than hypocrisy and the fabled ostrich seeking to hide by covering up its own eyes represents the height of good sense compared to the people who will not see the evils of venereal disease all about them. What an awful sensation it would make if it were reported that over 100,000 cases of a particular class of contagious disease occurred in New York City and were not mentioned in the Health Reports! Yet this is literally what happens with regard to the most contagious of diseases.

The time is ripe for the practical effort to be made to change this state of affairs. The new authorities of the municipal health board should at once accept some of the suggestions that the Committee makes. The gradual adoption of others will only be a matter of time, for the benefits to be reaped from this new departure in municipal health matters will soon be realized.

The Report can be commended to health authorities throughout the country as the conservative, thoughtful conclusions of men who, not only know conditions as they are, but have given fruitful study to the solution of the problem of amelioration of the present unfortunate state of affairs.

THE NEW YORK MEDICAL SOCIETY.

We are glad to be able to present to our readers this week the inaugural address of the new president of the Medical Society of the County of New York. Dr. Van Fleet may well be pardoned if he finds much to be proud of in the ninety-six years' existence of the Society.

As a matter of fact, however, he has been rather modest than overenthusiastic with regard to what the New York County Medical Society

has accomplished. That Society constitutes the main element of the State Society. Strange as it may appear, the panegyric of that body was heard from the lips of the last retiring president of the American Medical Association at the St. Paul meeting in June. Dr. Reed said in his presidential address, as reported in the MEDICAL NEWS, June 8, 1901:

"To-day there are forty-eight State or Territorial licensing boards, most of them composed of representatives of both the regular and the sectarian schools of practice. The laws of the different States are of varying efficiency. The one procured by the Medical Society of the State of New York, at the price of yet maintained excommunication from this body stands to-day as the model of excellence for the entire country."

The opprobrius excommunication for the time being of the entire profession of the great Empire State, Dr. Reed found most extraordinary, and all the more so as similar action was never taken with regard to a number of States that by overt act, if not by open declaration, had taken an equally non-conformist position. These are stronger expressions than any that Dr. Van Fleet uses, and they come with all the additional force of formal official opinions.

It is evident, then, since at last there has come to both parties the realization of the misconception that caused disunion, that we may look for a speedy reconciliation. The Medical Society of the State of New York deserves the most respectful consideration if it shows its willingness to enter the fold of the National Association from which, by an unfortunate misunderstanding rather than any clash of principles, it has been so long excluded.

Let us hope that the present movement toward reunion will result in the obliteration of a feud for which there has never been sufficient reason and that now in the course of time has become merely a heritage whose significance it is hard to realize fully, so obscured has the tradition of its origin become.

THE PATHOLOGICAL INSTITUTE.

THE clouds of disagreement regarding the director of the New York Pathological Institute for the Insane have finally rolled away and the State Lunacy Commission announce the appointment of Dr. Adolf Meyer as Director.

We heartily commend this action and feel that a man has been found who will be able to carry out the ideal program planned for this work by the founders of the Pathological Institute; and we confidently hope that American psychiatry will be enriched by the efforts of the Empire State.

ECHOES AND NEWS.

NEW YORK.

Appointment of Dr. Weyman.—Dr. M. B. Weyman, of New York City, has been appointed first assistant physician at the Manhattan State Hospital, at a salary of $2,000.

Columbia University Appointments.—It is reported that Dr. William K. Draper (P. & S., 1888) is to be appointed instructor in medicine at Bellevue Hospital for the medical faculty of the College of Physicians and Surgeons, and that Dr. A. M. Shrady (P. & S., 1893) is to obtain the position of instructor in physical diagnosis made vacant by the appointment of Dr. Draper.

New York County Medical Society.—A stated meeting will be held Monday, December 23d, with the following interesting program: Papers by Dr. Joel E. Goldthwait of Boston on Osteo-myelitis, Dr. R. Taylor of Baltimore on Its Clinical Aspect, Symptoms and Differential Diagnosis; Dr. H. A. Wilson of Philadelphia on Tuberculous, Rheumatic and Other Affections of Joints; Dr. A. M. Phelps of New York on The Mechanical and Operative Treatment of Such Joints.

Eastern Medical Society.—The Eastern Medical Society of New York City held its annual meeting December 14th. The following officers were elected for the ensuing year: President, Dr. A. Abrahams; First Vice-President, Dr. Joseph Barsky; Second Vice-President, Dr. E. K. Brown; Secretary, Dr. Maurice Fishberg; Treasurer, Dr. B. Gordon; Chairman of Ways and Means Committee, Dr. A. Hymanson; Chairman of Committee on Ethics, Dr. A. A. Himovitch; Trustees, Drs. A. Brothers and William S. Gottheil.

Columbia Registration.—The annual catalogue of Columbia University, which will be out next week, will show a registration of over 5,000 for the first time in the history of the college, exclusive of the 838 pupils in the experimental schools in Teachers' College. The total is 5,041 officers and students. Of this total over 800 are in the Medical Department.

Manhattan Dermatological Society.—On Friday evening, December 6th, the Manhattan Dermatological Society held a meeting at the rooms of the Medical Society of the Borough of The Bronx. The meeting was called to order by Dr. Wm. T. Gottheil.

Dr. E. S. Cocks showed a girl with *favus of the forearm.* This region showed a typical patch and the microscope corroborated the diagnosis.

Dr. Kinch presented a *mouse with favus* of the ears, forehead and back. Its occurrence in domestic animals and the transmission to human beings was discussed at length. In answer to several questions, Dr. L. Weiss gave the differential diagnosis between favus and ringworm.

Dr. Gottheil presented a classical case of *favus capitis,* showing the affection in its various stages and the results of the destructive process. Dr. E. L. Cocks said that in the treatment of favus attention must be given to exclusion and separation of the patients, to epilation, and antiparasiticides. Dr. Abrahams lauded

carbolic acid and Dr. J. Sobel had seen good results from formalin, properly diluted and carefully applied.

Dr. R. Abrahams showed a woman with *syphilitic* ulcerations of both legs, the result of broken down gummata. Antisyphilitic treatment caused marked improvement. The treatment of ulcerations in general was given by Drs. Abrahams, Kinch and Sobel.

Dr. Oberndorfer presented a case of *confluent psoriasis* and another of *seborrheal eczema*. The points of distinction were carefully considered.

Dr. J. Sobel presented a case of *erythema multiforme* involving the face, trunk and arms. Abdominal pain preceded the outbreak. Dr. L. Weiss showed a case of *lues* with a precocious tertiary stage and a case of *lichen planus*. Dr. Gottheil presented for Dr. Pisko a typical case of *lichen planus*. Dr. B. Ochs presented a man with *lupus erythematosus* on the right side of the face and scalp. Dr. Gottheil showed a case of *aggravated scabies*. Dr. Geyser presented two cases of *lupus vulgaris*, one of which was cured by the X-ray, the other being under treatment. Dr. Gottheil showed a case of *urticaria vesiculosa*. The uses and advantages of ichthyol in dermatology were discussed by Drs. Weiss, Abrahams and Sobel.

Member of Lunacy Commission.—It is said that Governor Odell has asked Mr. Daniel M. Lockwood to accept an appointment as the legal member of the State Commission in Lunacy, to fill the vacancy caused on July 1st last, by the resignation of William Church Osborne of New York City.

New York County Medical Association.—At the December meeting of the Association, held on Monday evening last, two matters of general interest were decided at the executive session. The question of medical reunion in New York State, as brought up by the appointment of a committee of the Medical Society of the County of New York, was treated in a report from the Executive Committee and the question of association medical defense in suits for alleged malpractice was taken up in a practical way.

The Executive Committee reported the receipt of an invitation for the appointment of a committee to confer with a similar committee from the Medical Society of the County of New York with a view to bringing the present discussion in the New York profession to an end. As the New York County Medical Association is entirely dependent on the New York State Medical Association, it cannot act in the matter. The Executive Committee suggests that the New York Medical Society present to the State Society the advisability of appointing a committee to confer with a similar committee from the State Association. The New York County Medical Association is eminently desirous of medical harmony and will use its influence with the State Association for the accomplishment of union. This report was adopted by the Association.

The Committee on Medical Defense reported that they had arranged the details of the method by which the New York County Medical Association can assume the legal defense of members for alleged malpractice. This will consist only in an extension of the legal arrangements by which violators of the laws for the regulation of medical matters are brought to justice. The fixed sum of $1,500 per year is to be paid to the Medical Association counsel and he is to assume the defense of members in all suits as far as the Court of Appeals. On motion this scheme of medical defence as outlined by the Committee was adopted provisionally until the New York State Medical Association shall have made definite arrangements for the defence of its members throughout the State.

Director of Pathological Institute.—The reorganization of the Pathological Institute of the New York State Hospitals, made necessary by the resignation of the former director, Dr. Ira Van Gieson, early last summer, has been proceeding slowly. As there are probably but three or four men in the United States capable of fulfilling in the highest degree the duties of such a position, the Commission in Lunacy, consisting of Dr. Frederick Peterson of New York, President, and Hon. Wm. L. Parkhurst of Canandaigua, have been looking over the ground for months with the view of selecting one worthy of being a successor to Dr. Van Gieson. The Civil Service Commission, after an examination of prospective candidates held December 7th, have certified to the eligibility of Dr. Adolf Meyer of the State Hospital and Clark University, Worcester, Mass., and he has been appointed by the Lunacy Commission to fill the position of Director of the Institute.

Dr. Adolf Meyer was born in 1866 at Zurich, Switzerland. A graduate of the Zurich Gymnasium, he studied medicine at the University of Zurich from 1885 to 1890 under the guidance of Professors Klebs, Forel, etc. During a year of post-graduate studies in Paris, Edinburg and London, he devoted his attention more and more to neurology, and on his return to Zurich he worked in the laboratory and clinic of Professor Forel, and, in 1892 he published a study on the "Forebrain of Reptiles." After a sojourn in Vienna, Berlin, and another month with Professor Dejerine in Paris, he went to Chicago, and from 1893 to 1895 he was pathologist at the Illinois Eastern Hospital for the Insane and Docent in Neurology at the University of Chicago, until he was called to Worcester, Mass., as director of the clinical work and laboratory of the Worcester Insane Hospital and Docent in Psychiatry at Clark University. In 1896 he made an extensive study of insanity in Europe, especially under Professor Kraepelin at Heidelberg, and since then he has carried out the plan of combining scientific laboratory research with the practical clinical work of a large hospital for the insane at Worcester.

The most important of his later publications are: "A Critical Review of the Data of Neurology" in the Jour. of Com. Neurology, Vol. VIII., Parts 3 and 4, and a study of a new form of degenerations in the central nervous system, published in Brain, 1901.

In June, 1901, at the 450th anniversary of the University of Glasgow, the degree of LL.D. was conferred on him as delegate of Clark University.

The scientific and clinical work of the reorganized Institute will be begun as soon as possible in a building connected with the Manhattan State Hospital for the Insane on Ward's Island. The scheme of investigation and research will be developed along lines to be formulated by Dr. Meyer in association with the Advisory Board of the Pathological Institute appointed not long ago by the Commission in Lunacy. This Board consists of Prof. Cattell, Department of Psychology, Columbia University; Prof. Ewing, Department of Pathology, Cornell University; Prof. Herter, Department of Pathological Chemistry, University and Bellevue Medical College; H. C. Bumpus, Department of Biology, American Museum of Natural History; Prof. Hun, Department of Nervous Diseases, Albany Medical College; Dr. C. W. Pilgrim, Superintendent Hudson River State Hospital for the Insane, Poughkeepsie; Dr. A. E. Macdonald, Superintendent State Hospital for the Insane, Ward's Island; Dr. Frederick Peterson, President of the Lunacy Commission *ex officio*.

It is felt that with a new director of the attainments

of Dr. Meyer both in pathology and in experience among the insane, and with an Advisory Board constituted of such men as are those just named, the plan of work of the Institute will be organized on a basis which should be satisfactory to the medical profession, to the physicians in the State asylums for the insane, the various universities of the State, to scientists in general, and last, but not least, to the taxpayers who support the Institute, and who deserve to expect from it results that shall be of practical value in the care, treatment and cure of the insane. Dr. Meyer is to be left free to select his assistants in the various departments of the laboratory work, but will be assisted in this selection by the Advisory Board.

PHILADELPHIA.

Smallpox in Philadelphia.—The week ending December 12th showed another large increase in smallpox cases, the number being 125, with 8 deaths. The Auxiliary Vaccine Corps organized by the Director of Public Safety has vaccinated about 11,000 persons. As a rule the physicians have been received gladly, the people being willing to be vaccinated. The work will be continued until the entire city has been covered. Dr. Alfred P. Gray of Frankford has lately developed smallpox, he being the second physician in the city to contract the disease.

Penny Bath-House to Be Erected.—The Public Bath Association of this city will erect at 718 Wood Street a thoroughly modern bathing establishment to be conducted for the poorer classes of people. It will be operated on the principle of London establishments, an admission fee of one cent being required from each bather. The structure will be equipped with massage, electric and needle baths, plunge and shower baths, and a sixty-foot swimming pool. The success of this establishment will mean the erection of others of the same style throughout the city.

Death of Dr. Leake.—Dr. Ephraim F. Leake, of Frankford, died December 13th at the age of eighty years, being one of the oldest of the graduates of the University of Pennsylvania at that time. He took an active interest in politics and because of his efforts in favor of reducing trolley rates he was called "The father of five-cent fares." He was in active practice until two weeks before his death.

Enlargement of the American Journal of the Medical Sciences.—With the coming of the New Year, that Nestor of medical journalism, The American Journal of the Medical Sciences, announces an increase in the number of its pages. Sixty-four pages will be added to each issue, all of which will be devoted to the accommodation of original articles. The total of 192 text pages in each number makes it not only the largest of monthly medical periodicals, but also enables it continuously to cover special fields which perforce have heretofore received intermittent attention. The peculiar advantages enjoyed by The American Journal as the organ of the best class of the profession insures to its pages the qualities of authority and interest. It is an honor to American medicine, and we wish it a continuation of its long and successful career.

Sweeping Vaccination Order by University.—A regulation just adopted by the University of Pennsylvania is as follows: "From and after December 24, 1901, every student and every member of the teaching body in all departments of the University and every employee shall exhibit satisfactory evidence to the Dean of the department that he or she has been successfully vaccinated within five years or is incapable of successful vaccination, and that any person failing to comply with this requirement shall be excluded from attendance at any of the lectures, studies, laboratories, or other departments of the University." Physician's certificates must be filed with the Dean.

Ichthyol in Tuberculosis.—At the County Medical Society, December 11th, Dr. Charles T. Spangler of Kane, Pa., read a paper extolling the use of ichthyol in pulmonary tuberculosis. Kane is a well patronized climatic resort, but Dr. Spangler's experience has led him to believe that the people who improve under climatic treatment alone are only a favored few who would improve under any favorable condition or change. As an adjunct he has found that ichthyol yields admirable results. The odor, taste, and eructations can be to a great extent avoided by giving the drug in capsules. If eructations persist, give the remedy only after breakfast and at bedtime. An elastic method of administration must be followed. After the first week of its use the patient's cough lessens and the sputum loses much of its density. Further use causes continued improvement. The drug is of little value in the acute complications of consumption and should be suspended at such times. In cases where obstinate cough or inflammation of the upper air-passages follows influenza, etc., the patient should be put on ichthyol at once instead of delaying its use until tuberculosis is marked. Dr. Spangler reported a number of cases to substantiate his claims regarding the use of ichthyol.

Camden Physicians Favor Home for Incurables.—The Camden County Medical Society at a recent meeting adopted the following: *"Resolved,* That this Society recommend the enactment of a law providing for the establishment of a sanatorium, under State supervision, for the treatment of incipient cases of tuberculosis, which shall afford the best facilities for the personal care of the subject and the cure of the disease.

Scholarship in Rockefeller Institute Awarded.—Scholarships in the Rockefeller Institute for Medical Research have been awarded to four students from the University of Pennsylvania. Three are from the Pathological Laboratory—C. M. Duval, E. B. Vedder, and Dr. F. P. Gray—and one, Dr. G. H. Gildersleeve, from the Hygienic Laboratory.

Experiments on the Formation of Bile Pigments and Bile Acids.—Dr. A. C. Croftan, holder of the Woodward Fellowship in Physiological Chemistry in the Pepper Laboratory, gave at the Pathological Society, December 12th, the results of some experiments regarding the formation of bile acids. He stated that there is sufficient proof to demonstrate that the formation of bile and bile acid is the product of hepatic cells. He is clearly of the opinion that these materials are the products of a ferment and that they may be formed outside the body by the use of a ferment. This ferment has such composition that it cannot by any known means be differentiated from trypsin. If a solution of hemoglobin to which sugar and a liver lobule are added be placed in an incubator at body temperature for one week the fluid becomes clear and a brownish precipitate forms. This precipitate contains bile and the supernatant fluid contains bile acids. Now, if trypsin be substituted for the liver lobule in the above experiment, exactly the same changes take place. Dr. Croftan claims that trypsin reaches the liver from the pancreas by means of the circulation. Trypsin is found in muscle and in the kidney and has also been demonstrated in white blood-cells. Since hemoglobin, dextrose and trypsin are present in various organs, the claim is made that the liver is not the only seat of bile and bile acid production. The

relation of the formation of bile and bile acids to the removal of the pancreas and diabetes was then discussed. If the formation of these products depends upon the presence of trypsin, this, with the known fact that removal of the pancreas causes diabetes, explains the latter. When trypsin is not produced there is no ferment to destroy the dextrose of the tissues and that material is eliminated by the kidneys. Dr. Croftan has also discovered very recently that the suprarenal gland also contains a diastatic ferment.

Somnolence Caused by Middle-Ear Disease.—Dr. W. G. B. Harland recently reported at the County Medical Society a case of somnolence apparently due to a middle-ear condition. The patient was a boy of fourteen in whom somnolence was almost continuous, he not being able to run errands or to attend to any work. Treatment in a medical dispensary had been futile. A small amount of cerumen was found impacted in the left ear. Removal of this was followed by the discharge of a few drops of pus and revealed a large perforation of the drum. In three weeks the boy was well. After three months another slight attack occurred, but soon disappeared when the ear was cleaned. The boy, in all other particulars was absolutely normal. This, with the result of treatment, seemed to prove conclusively that the ear condition was the cause of the unusual degree of somnolence. It is supposed that pressure was the immediate cause of the symptom.

CHICAGO.

Chicago Lying-In Hospital.—The annual meeting of the Board of Directors of the Chicago Lying-In Hospital and Dispensary was held two days ago. It was decided to broaden the scope of the work, and to this end the Board of Directors was increased to nine members, the Woman's Board increased to twenty-seven, and the Medical Board arranged so that its members are to be chosen from the three best known of the Chicago medical colleges. The Board of Directors is to be chosen so as to have three members from each side of the city. They are to be divided into three groups and each group is to serve three years. The physicians who are to have charge of the medical affairs are Dr. Joseph B. De Lee of the Northwestern University Medical School; Dr. Frank B. Earle of the College of Physicians and Surgeons, and Dr. J. Clarence Webster of Rush Medical College.

Spread of Smallpox.—The State Board of Health reports smallpox spreading in Illinois, especially in the central and southern parts, where in two or three localities the public schools have been closed in consequence. In Chicago there have been six cases of the disease since the early part of October, after an interval of entire freedom from August 12th. Of these there were three in one family contracted from a man who had been in contact with smallpox cases at Rochester, Ill. The remaining three were imported cases, and no one of the six had never been vaccinated, although one of the Chicago cases was in attendance at the Parkside School on a fraudulent certificate of vaccination signed by a physician. The details of these cases again emphasize the lesson that no efficiently vaccinated person need fear smallpox, and that none other is safe while the disease is present in the country.

Scarcity of Physicians to Fill Positions Owing to Small Salaries.—Difficulty is being experienced by the County Civil Service Commission in securing candidates for positions as physicians at the County institutions. Although notices of an examination to be held December 16th have been posted for three weeks, the responses are coming in with unusual slowness, and it is possible that the examination will again be postponed. The report of the special committee that is reorganizing the Dunning institutions, it is expected, will provide for ten or twelve new positions. To fill this list only six physicians have so far announced their intention of entering the examination. In order to secure an adequate eligible list, it is urged that the County Board take steps to make service on the medical staffs of the institutions more popular by raising the salaries. At present physicians at Dunning receive salaries in some instances as low as $60.00 a month.

Chicago, Milwaukee and St. Paul Railroad Surgical Association.—The ninth annual meeting of this Association was held in this city at the Great Northern Hotel, December 12th and 13th. The following papers were read and discussed: Injuries of the Ankle Joint, by Dr. W. N. Kendrick, Austin, Minn.; Fracture of the Patella, by Dr. Hugo Philler, Waukesha, Wis.; A Case of Abdominal Disease, with Post-Mortem Specimen, by Dr. B. F. Dodson, Berlin, Wis.; Amputation in Railway Practice, by Dr. H. B. Hemingway, Evanston, Ill.; Fracture of the Femur, by Dr. P. J. Adair, Anamosa, Iowa; Observations of Various Means of Bone Fixation, by Dr. D. S. Fairchild, Clinton, Iowa; Management of Severe Burns, by Dr. Allen Staples, Dubuque, Iowa; Plastic Surgery of the Face and Eyes, by Dr. C. D. Wescott, Chicago, Ill.; Some Nervous Phenomena Following Accidents, by Dr. S. A. Spilman, Ottumwa, Iowa; Postmortem, Antemortem, and a Celebrated Case, by Dr. H. H. Clark, Mount Gregor, Iowa; Thermic Trauma, by Dr. E. O. Plumbe, Rock Valley, Iowa. There were over one hundred physicians in attendance at the meeting.

The Conservative Treatment of Appendicitis and Fallacy of the Starvation Cure.—At a meeting of the Chicago Medical Society, held December 11th, Dr. J. Henry Carstens of Detroit, Mich., read a paper, by invitation, on this subject. After citing his observations in relation to this disease, he summed up by saying that the conservative treatment of this disease consists in prompt operation, and that the starvation method of procrastination is vicious and has cost many lives, because it is used as an excuse to dally with patients that should be promptly subjected to the removal of the organ. A spirited and lengthy discussion followed the reading of this paper. The radicalists were Drs. John B. Murphy, Alexander Hugh Ferguson, and the author of the paper. Others, who participated in the discussion, and whose views were more conservative in tone, were Drs. Christian Fenger, Arthur Dean Bevan, L. L. McArthur, A. I. Bouffleur, D. W. Graham, and others.

More Room at Dunning.—Immediate changes to afford room for 200 additional patients at the Dunning institutions will result from the investigation of the special advisory commission. One-half of the consumptive hospital will be fitted up for insane patients to accommodate those who now are sleeping on the floors of the old hospital. The large dance-hall is to be turned into a dormitory, while the maternity hospital is to be converted into a ward for children at the poorhouse. Dr. Frank Billings and Dr. Hugh T. Patrick were appointed to conduct the professional reorganization of the institutions, while Dr. Billings and Mr. E. P. Bicknell will decide on the style of new buildings.

Traffic in Dead Bodies.—Trafficking in cadavers will be investigated by the Grand Jury. The attorney for the State Board of Health, Mr. Shaw, who, with Dr. M. O. Heckard, Registrar of Vital Statistics in

the City Health Department, attempted to have the subject inquired into by the November Grand Jury, but coming with their complaints late in the session, the matter was dropped until the December Grand Jury was called. Chief among the complaints is the attempted shipment from the State on November 6th of 8½ cadavers under the title of "Second-hand laundry machinery." The consignment was to one "J. R. Jones, Brashear, Mo." Dr. F. Schoenliber, connected with the Harvey Medical College, was charged with the violation of the statutes, and was arrested. Justice Hall dismissed the charge for lack of evidence. Attorney Shaw was not satisfied with this. Mr. Shaw has, it is said, received information concerning trafficking in cadavers by undertakers in the outskirts of the city to points outside the State. These complaints he will ask to have investigated.

GENERAL.

Leprosy in the Hawaiian Islands.—Five years ago there were 1,300 lepers in Molokai. Now there are only 900, and Superintendent Reynolds believes that leprosy is being slowly but surely eradicated from the Hawaiian Islands.

A New Biological Journal.—A new journal devoted to the statistical study of biological problems has just appeared, bearing the title Biometrica. Dr. C. B. Davenport of Chicago is the American editor.

Boston's Smallpox Epidemic.—Notwithstanding the efforts of the Health Department to control the disease, smallpox continues to rage in Boston. The report of the Health Department December 10th shows 12 new cases in twenty-four hours. This is a slight decrease from the day before, but an increase over the middle of last week, when such discouraging reports were made that doctors and health officials were led to believe the disease was on the wane. Another appeal has been issued to continue vaccination.

Study of Foods.—The united efforts of the profession should aid Professor Atwater and his associates at Wesleyan University, at Middletown, Conn., in the move just made to receive from Congress an increase of $10,000 in the annual appropriation for the development of the study of food and nutrition. This will make the appropriation $30,000. The extra money will be used for the extension of the work along several lines, among them being dietaries of farmers and rural and urban wage-workers, including those in the South; studies with reference to the utilization of nutrition; investigations in public institutions, and studies in food supply of people in the tropics, with special reference to the new national possessions. The variety of the investigations has to do with kinds, amounts and costs of food actually bought and sold by members of families of mechanics, farmers and professional men, people in the slums of New York and Chicago, negroes and the so-called "poor whites" of Virginia, Alabama and Tennessee, native Mexicans and half-breeds in New Mexico, and Chinese in California. The investigation would be extended to others if they could be found or reached, but it now touches a greater number of persons than any series of experiments on any scientific subject ever before carried on in America or in any other country and is worthy of support.

Boer Death-Rate High.—A bluebook was issued by the Colonial Office December 14th, containing a detailed return of the deaths of Boers in the concentration camps in South Africa in the months of October and November and also during the six months from June to November inclusive. The deaths of whites in the six months numbered 12,441, including 10,113 children. The death-rate per 1,000 per annum for the entire mortality in all the camps increased from 109 in June to 338 in October, and sank to 284 in November. The death-rate per 1,000 per annum for children in the month of September was 433, in October 572 and in November 469.

Aseptic Barber-Shops.—The Board of Health of San Francisco has, according to The Sun, adopted a code of rules for the sanitary regulation of that city's barber-shops and the rules are strict enough to make the New York barber gasp. Inspectors have been appointed to visit the shops and report violations of any of the regulations. First of all, the sponge has to go in the San Francisco barber-shop. The use of the sponge is absolutely prohibited. The powder-puff goes with the sponge. Barbers are required to apply powder to customers' faces with clean towels or absorbent cotton. That a separate clean towel must be used on every person, under the rules, almost goes without saying after that. That, however, is only the beginning of sanitary discipline. "Sanitary hair-brushes" must be used and sterilized by immersion in boiling water or a weak solution of formalin, and the same with shaving-mugs and brushes after every separate use. Razors must be wiped with 95-per-cent. alcohol before and after use on any person. Needles, tweezers, forceps and other instruments must be disinfected in boiling water or 3- or 5-per-cent. formalin solution immediately after using and thoroughly dried by passing quickly through a gas or alcohol flame. Scissors and clippers must be treated likewise. Floors must not be swept but mopped up with a solution of corrosive sublimate. As to the barbers themselves they must keep their nails short and clean, under penalty of a fine. They must not breathe on the razor strops nor wipe them off with the hand. They must wash their hands "thoroughly" immediately after serving each customer and must not blow loose hairs away with their breath.

Bad Quinine in the Philippines.—In its issue of last week the Oil, Paint and Drug Reporter contains a statement from its Washington correspondent that trouble occurred nearly two years ago in regard to a shipment of quinine to the Philippines. In the summer of 1898 the Surgeon-General's office undertook to obtain a large quantity of drugs on short notice for use in the Philippines. Included in this order were 12,500 bottles of two-grain quinine tablets (500 tablets to the bottle). Soon after this consignment, which was furnished by a San Francisco house, reached the Philippines there was complaint that the tablets were adulterated. An investigation was made and as a result 12,227 of the 12,500 bottles were sent back to the contractors. The contractors represented that any adulteration which might be found in the tablets was due to no fault of theirs and they complied with the requirement of the department that they substitute for the rejected tablets others of standard purity.

North Texas Medical Association.—The last regular meeting of this Association met at Greenville, Tex., December 10th, 11th and 12th, under the presidency of Dr. R. F. Miller. The following interesting program was given: Report of the Chairman—Some Observations on the Continued Fevers of North Texas, by R. W. Baird, Dallas; Typhoid Fever—Report of Two Cases, by Will Cantrell, Wolfe City; Treatment of Typhoid Fever, by C. M. Grigsby, Kaufman; Tubercular Nodules of the Bowels, by J. D. Burt, Farmersville; Dermatitis Medicamentosa, with Report of Case, by J. B. Shelmire, Dallas; Symptoms and Treatment of Invasion of Nasal Cavity by the Texas Screw-worm, Report of Three Cases, by H. A. Burrows, New Bos-

ton; Incubation for Laryngeal Diphtheria, by J. W. Bourland, Dallas; Functional Neuroses of the Menopause, Report of a Case, by A. B. Small, Waxahachie; Adenoids and Their Complications, by E. H. Carey, Dallas; Subject Unannounced, by J. H. Erwin, Kaufman; Lobar Pneumonia, by T. R. Black, Blossom; The Pupil and Visual Field in Cerebral Diseases, by S. L. Terrell, Dallas; Surgical Tuberculosis, by L. P. McCuistian, Paris; The Present Treatment of the Hypertrophied Prostate Gland, by J. T. Wilson, Sherman; The Eye Symptoms in Fractures of the Skull, by Jno. O. McReynolds, Dallas; A Case of Cerebellar Tumor, by B. E. Hadra, Dallas; Injuries of the Spine, by Le Roy Long, Caddo, I. T.; Thoracotomy, by J. C. Carleton, Bonham; Extravasation of Urine Following Traumatism of the Urethra, by R. R. Walker, Paris; Traumatic Empyema, by J. E. Dodson, Vernon; Report of a Case, by T. L. Barnett, Midlothian; Report of a Case of Congenital Cerebral Syphilis in a Child Ten Years Old, by G. W. Foscue, Waco; Report of Surgical Cases, by S. E. Milliken, Dallas; Management of Normal Labor, by J. C. Carlton, Bonham; Uterine Misplacement, by A. H. Lindsay, Paris; Mastitis, Cause and Treatment, by Ellen L. Dabbs, Fort Worth; Report of a Case of Uterine Fibroids Treated with Thyroid Extract, Recovery, by Jas. T. Jelks, Hot Springs; Curette in Gynecology, by J. F. Curry, Rockwall; Manual Manipulation as an Aid to Parturition, by C. A. Gray, Bonham; Endometritis, by O. C. Buster, Pilot Point; Abortion, by W. H. Births and Deaths in France.—For those who claim that nothing good can come out of France, the recent statistics of births and deaths will prove of satisfaction. In 1899 the excess of births over deaths was 31,394, giving the hope that France was slowly rebuilding up its population, but in 1900, on the contrary, there was an excess of 25,988 deaths over births. In only two Departments, the Seine Inférieure and the Cantal, the excess of births over deaths in 1900 was greater than in 1899. In thirty other Departments the number of births in 1900 was greater than that of deaths, but that excess of births was inferior to that of 1899. On the other hand, in 55 Departments the number of deaths in 1900 was larger than during the preceding year; whereas, in 1899 that increased mortality existed in only 43 Departments. If the number of births diminished, the number of marriages increased by 3,332 in 1900. Divorces were less numerous. Examining the births, the report notes that there were only 73,121 illegitimate children born in France in 1900, and that 19,141, or almost one-third of them, were born in Paris. The statistics, not only of 1900, but of previous years, show that in France 21 male children are born to every 20 females. Nevertheless, the feminine population of France is a little larger. Men die earlier than women. Quoting the statistics of the last ten years, the correspondent of the *Temps* affirms that it is the legitimate unions which are productive of that happy majority of the birth of male children. Taking the average of the last ten years, the writer shows that of the annual offspring of those legitimate unions, 398,354 were males and only 381,030 females. This predominance of the male sex is, according to the *Temps* correspondent, who has studied the statistics for many years, so constant as to be a sort of law. However, the predominance of the male sex in the offspring of illegal unions is much less marked. In this category it is interesting to note that the figures show the average for the last ten years is 37,674 males and 36,817 females.

Changes in the Medical Corps of the Navy.—For the week ending December 14th: H. H. Hass, Past Assistant Surgeon, detached from Norfolk Navy Yard, and ordered to the "Kearsarge" for duty with the marine detachment; F. M. Furlong, Assistant Surgeon, when detached from New York Hospital, ordered home on sick leave for two months; P. E. McDonnold, Assistant Surgeon, detached from the "Constellation," when discharged from Naval Hospital, New York, and ordered home with one month's sick-leave; W. M. Garton, Assistant Surgeon, detached from the Naval Academy and ordered to the Naval Hospital, New York; J. B. Dennis, Assistant Surgeon, detached from the Naval Hospital, New York, and ordered to the Naval Academy, upon reporting of relief; J. B. Buchanan, Assistant Surgeon, ordered to the "Columbia"; N. H. Drake, Surgeon, ordered to the "Philadelphia"; J. Cowan, Pharmacist, detached from the Boston Navy Yard, ordered home to wait orders.

Obituary.—Dr. Edward H. Bemis of Glens Falls died on Monday last from a stroke of apoplexy.

Dr. Leslie M. Sweetman, a well-known surgeon of Toronto, Canada, died December 11th in the Johns Hopkins Hospital of blood-poisoning. Several weeks ago, while cleaning his hands after an operation in the hospital of the University of Toronto, he received a small puncture in one of the fingers of his right hand from the nail-brush he was using.

Dr. F. A. Utter died suddenly on December 10th at 103 West 71st Street, in the sixty-first year of his age. Dr. Utter was well known on the West Side and was a member of the Grand Army and of the New York County Medical Society.

Dr. Rush S. Huidekoper died December 15th from a complication of diseases said to have been contracted during the Spanish-American War, in which he served. Dr. Huidekoper was United States Commissioner General to the exposition at Hamburg in 1883, and in 1893 was appointed chief surgeon in the army with the rank of lieutenant-colonel. He was forty-seven years of age. Dr. Huidekoper was born in Meadville, Pa., and was educated at Phillips Academy, Exeter, and at the University of Pennsylvania, where he was graduated in medicine in 1877. Later he studied at the National Veterinary School at Alfort, France, and in the laboratories of Virchow, Koch, Pasteur, and Chauveau. Later he was connected with the University of Pennsylvania and the New York College of Veterinary Surgery as professor of internal pathology and contagious diseases. For many years he occupied high medical positions in the Pennsylvania National Guard. His appointment as Chief Sanitary Inspector of the military camp at Chattanooga after the Spanish war excited much adverse comment, and he resigned. He published several works on animals and was editor of the *Journal of Comparative Medicine and Veterinary Archives.*

BYWAYS OF MEDICAL LITERATURE.

PATHOLOGY IN FICTION.

IN recent years the introduction of pathology into fiction has come to be quite the fashion. Distinctly medical ideas that are usually not discussed in any but exclusively medical circles sometimes receive thorough ventilation before the public in this way. The late Grant Allen, under one or other of the aliases he used to assume in order to conceal the amount of writing he was doing, found a very interesting field in certain

problems in psychiatry and especially in the department of criminology. Usually when the medical topic introduced into a novel is especially risky, the writer is likely to be a woman. It was Mme. Sarah Grand, in "The Heavenly Twins," who gave the dear non-medical public that delicious pathological morsel in the description of a syphilitic infant as "a little old man with a cold in his head." Another successful woman novelist has just attempted quite as forbidding a subject. Her novel has been hailed as the book of the year and is actually one of the best selling of the moment. The novel is "Sir Richard Calmady," the author's name, Lucas Malet, being the pseudonym for Mrs. Mary St. Leger Harrison, the daughter of the late Charles Kingsley, the clergyman novelist and poet so well known a generation ago in England. As her father occupied himself toward the end of his life mainly with "social" subjects, perhaps the daughter's choice of theme should not be a matter for surprise.

The first part of "Sir Richard Calmady" introduces a telling incident that depends for its interest on the supposed influence of maternal impressions. Young Sir Richard Calmady and his wife have been married but two or three months when the husband is brought home one day with both his legs badly crushed. Amputation is required. Needless to say the young wife is intensely disturbed by the sad accident and by the consequent death of her husband. The scene in which he is brought in maimed is indelibly impressed upon her. A baby boy is born some six months later and, although the upper part of his body is well formed and beautiful, the lower part is horribly maimed as though the legs had had been cut off above the knee. At first the mother is not told of this deformity. Then it is broken to her gently and shortly after in a powerful scene the author describes her maternal feelings as she unwraps her baby boy. The boy is brought up so carefully as almost not to realize his difference from other children. Late on in life he falls in love with a handsome young woman. At first she accepts him, but the realization of all his deformity turns her from him and she refuses him.

Then in a series of chapters in a section of the book called the "Rake's Progress," the authoress brings out forcefully that extreme medical problem as to the sexual feelings of the deformed in the lurid light of the physical aversion that their deformity occasions in those who are capable of arousing their passion. The deformed Sir Richard Calmady goes to Naples, where not far from the scene of the orgies of the Roman Emperor Tiberius the passionate part of the cripple's life works itself out. His ultimate salvation is an attack of typhoid fever from which he is nursed by the proper person and returns to England to marry her and live happy ever after.

The problems involved in the book are undoubtedly of intense interest and are very close to the heart of Nature. The question of sexual feeling in the deformed has been the source of serious thoughts for many a medical man. It seems scarcely proper, however, to present such problems in detail to the general public. "Sir Richard Calmady," for all its truth to Nature and its excitation of sympathy for deformity, is apt to do more harm than good. Pathology has scarcely a place in fiction, and should as a rule be excluded.

LITERARY PATHOLOGY.

Another phase of pathology in literature (save the mark) is well represented by the following quotation from an article of Mr. Vance Thompson in the last number of the "The Philistine." The article has the very medical title "Red Corpuscles in Art." It begins thus: "The trouble with the arts to-day is that they are anemic. They are deficient in red corpuscles. This is true of the drama. It is true of music, painting, sculpture, poetry—all the arts. George Moore used to have a phrase for it. 'Art to-day,' he would say, 'lacks guts.' And so it does. Were I to use my own phrase, I should say that what we all lack is the Rabelaisian spirit." Later on occur the phrases: "Great art is always virile. The slim pallidities of Fra Angelico belong to a day of degenerate and monkish thought. Rubens' great blonde women are the solaces of the eternal fighting man. Read Rabelais, mes amis, and become Rabelaisian. Of such are the kingdom of art."

We fear that the good physician Rabelais, who in a rude time said rough things in a crude way, would not be overready to acknowledge his supposed disciples in this later generation who presume on vulgarity as an element of humor in defect of something better.

THE PLAGUE.

The last number of the *Quarterly Review* (London) contains a very informing article on the plague in which are reviewed seven recent books on the subject. Some of the information is startling enough. For instance, in Bombay alone in three years and a quarter 46,000 victims of the disease succumbed. In the whole Presidency, including the city, the plague mortality during the same period is reported as amounting to 252,000 persons. This gives a very good idea of the fearful ravages of the disease when the circumstances are favorable for its dissemination. On the other hand, how little liable the disease is to spread despite exposure under ordinary sanitary conditions may be gathered from the single case which occurred at Cardiff in Wales last year. The patient was a sailor and arrived at King's Lynn on a vessel carrying corn. When the unloading was finished two men were taken ill. One of them landed at South Shields, crossed England by rail to his home near Cardiff, was found to have plague and was removed to a hospital, where he died. This man was not infected when he left South America, as the voyage was much longer than any possible incubation period. He must have been inoculated while unloading the cargo, in which many dead rats were found. It is instructive to observe that in a long railway journey and during his illness at home this patient did not communicate the plague to any one, though he was brought ultimately in contact with very many persons before the recognition of his disease led to isolation.

A THERAPEUTIC BOOK.

The life of Robert Louis Stevenson by Graham Balfour would, it seems to us, be an excellent book to put into the hands of the discouraged consumptive making the fight for his life, finding the hours hang heavily and with no mental occupation to arouse and stimulate him to vitality. The courageous way in which Stevenson, during long years of fight with the malady that finally carried him off, nobly did his work and even laughed at his sometimes almost victorious conqueror, is one of the most inspiring things in the history of modern literature. When suffering from repeated hemorrhages he writes to an editor to say that he will have certain manuscripts ready if only "bluidy Jack," his pet name for recurrent hemorrhage, will let him. This is the very acme of bravery.

Several years before his death, he wrote to Mr. George Meredith, the English author, that for years he had not had a day's real health. "I have awakened sick and gone to bed weary and I have done my work unflinchingly. I have written in bed and written out of it, written in hemorrhages, written in sickness, writ-

ten torn by coughing, written when my head swam for weakness, and for long it seems to me I have won my wager and recovered my glove."

MEDICAL ARTISTIC TRUTH.

Most of our readers know "the boy and the geese" picture of the familiar patent medicine "ad." The story of it has just come out. We have heard of artists painting the portraits of newly-rich patrons so faithfully that the vulgarity of features was patent even to the sitter. At times, too, there has been a whisper of such conditions where the patron failed to see the conscious or unconscious' satire, but this beats all those. A distinguished American comic artist is said to have been asked to prepare a sketch for advertising purposes for the great cure-all. He drew the well-known set of figures, now so familiar to all New Yorkers, of the boy and the geese—the evident allusion to the sort of patrons the patent-medicine man hoped to have flock after him as he poured out his remedy before the public was lost on the advertiser. Now, in huge size, the boy and his geese following stare out from every important signboard. Only those who know the artist and the delicacy of his satire are "on to it" however, and we suppose the dear public flocks as anticipated after the remedy as it is poured out "for a consideration."

CORRESPONDENCE.

OUR LONDON LETTER.

(From Our Special Correspondent.)

LONDON, December 7, 1901.

DEATH OF SIR WILLIAM MACORMAC—AN EARLY PIONEER OF THE OPEN-AIR TREATMENT OF CONSUMPTION.

IT WAS with a shock that the medical world of London, and indeed of the United Kingdom, heard on December 4th of the sudden death of Sir William MacCormac. Only the day before he was sauntering about the streets, as was his custom not only of an afternoon, but of a morning, with a cigar in his mouth, a retriever at his heels, and the general appearance of a man who had nothing to do and did it very well. But to those who knew him as he was only two or three years ago, it was painfully clear that, like Falstaff, he had fallen away vilely. His trip to South Africa, though he did little in the way of work while he was there, seems to have laid the seeds of a dysentery of which he never quite got rid. He died at Bath, whither he had gone to take the waters. He was only sixty-five, which in these days of "grand old men" is the prime of life. The immediate cause of death seems to have been a heart seizure of some kind, but even before he went to Africa his constitution was undermined by a severe and prolonged attack of pleuropneumonia which nearly killed him a few years ago. He was a man of striking presence, standing some 6 feet 3 or 4 inches, as erect and as solid looking as a marble column. He was an imposing figure-head at professional "functions," and for this reason, among others, was five times elected president of the Royal College of Surgeons. He was secretary general of the International Medical Congress held here in 1881, and made a great impression on the foreigners present by the stateliness of his appearance. MacCormac was an Irishman by birth and education and at the outset of his career had no connection with any of the London hospitals or schools. This fact makes his rise to the position which he occupied at his death all the more remarkable, for it is by no means easy for an outsider to get a position on the staff of a London hospital of the first rank. MacCormac, however, somehow managed to get himself appointed assistant surgeon to St. Thomas's Hospital and he worked his way up steadily from the lowest rung in the professional ladder to the top. This is sufficient to prove that there must have been sterling worth and ability in the man. Yet, though not only popular but held in high esteem by his pupils, he was never taken very seriously by the profession. He was a good surgeon of the old school whose maxim was to cut through everything soft, saw through everything hard, and tie up anything that bled. But of scientific surgery in the modern sense he knew little and, I should imagine, cared less. He was in his proper element at a base hospital in a campaign; and it was his services as a volunteer surgeon in the Franco-German and Servian wars that first won for him the newspaper fame which he continued to enjoy till the end.

MacCormac was a favorite with the present King long before his accession and this brought his name prominently before the public. But he never had much practice, and this no doubt contributed to his popularity with his brethren of the knife. He had no enemies because he was not looked upon by any one as a rival. He was a genial Irishman, with perhaps less than his share of the wit with which his countrymen are credited; he was rich, having married an heiress; it was a runaway match, but it was a very happy one; he was a baronet and two knights rolled into one; he was happy in the possession of nearly all the orders, medals, crosses, stars, and ribbons, with which European monarchs decorate those whom they delight to honor. These things and the official honors freely bestowed on him by the College of Surgeons doubtless consoled him for the want of private patients. His official connection with the royal family made him popular in society and at public banquets; though his oratory was not inspiring, his conspicuous appearance shed a reflected dignity on the profession of which he was the accepted representative. Within the profession he was, as already hinted, a man of more *weight* than authority. But when the gaseous elements in his career have been allowed to evaporate, there will remain a solid residue of good work—not large in amount nor very precious in quality, but yet of distinct value. He discharged the onerous duties of surgeon to a great hospital and lecturer on surgery in a school largely resorted to by the graduates of our most famous universities with credit to himself and acknowledged benefit to his pupils. The mere possession of a fine presence could hardly have enabled him to do this. Nor is it every one who could write a book like his "Notes and Recollections of an Ambulance Surgeon" (during the Franco-German war), which has been translated into French, German, Dutch, Spanish, Italian, Russian and Japanese. MacCormac was a large-hearted man and to his friendly help not a few of the younger generation of St. Thomas men owe their success.

The death of Sir William MacCormac recalls the fact that his father, the late Dr. Henry MacCormac of Belfast, was an early pioneer of the "open-air" or, as it might more fitly be called, the rational treatment of consumption. As long ago as 1855 he published a book in which the policy of the open window and all the essential features of the modern treatment of tuberculosis were clearly set forth. Dr. MacCormac was an enthusiast and gave his life to the preaching of his sanitary gospel. The following passage from his book shows how fully he had grasped the vital truth to which the profession is only now being awakened. After stating that "a fresh, untainted, unprebreathed atmosphere, at all times and places, is the

one condition of treatment which nothing must interfere with or set aside," he goes on to say:

"The simple rule is to let the chamber atmosphere prove pure and untainted as is the open air itself, in which indeed the patient should otherwise spend as much time, in fact pause as much as his strength, the weather, the season and his means will permit. He must, in short, live in the open atmosphere, but then it must be the open atmosphere, and its wholesome influences coupled with, not thwarted by, house comforts and home shelter. The phthisical sufferer should spend as much time in the open air, in all seasons, as his strength and the weather will permit."

This, be it remembered, was written before Brehmer was heard of. Henry MacCormac went about as an apostle of his new doctrine to London, Edinburgh, Glasgow and other medical centers. But he was before his time and the mind of the profession was not ripe for his teachng. The general opinion of him seems to have been that much learning (he was a great linguist, philosopher and what not besides a physician) had made him mad. The reception he met with at the leading medical society of London, the Medical and Chirurgical, may be taken as a type of that which he got elsewhere. In 1862 he read before that body, which then as now represents all that is in an academic sense most "superior" in British medicine, a paper on "The True Nature and Absolute Preventibility of Tubercular Consumption." One learned Theban characterized the paper as a waste of time; while another protested that the Society should be protected against the reading of such productions! The end of the business was that the Society refused to pass the customary vote of thanks to the author. The incident, though amusing to the cynic, is painful to any one interested in the progress of the healing art. The history of medicine shows that it may almost be looked upon as a law of the evolution of medical thought that wisdom must cry out for years, sometimes for centuries, in the streets before any man regards it.

OUR PARIS LETTER.

(From Our Special Correspondent.)

NOVEMBER 29, 1901.

RESTAURANT FOR LATIN QUARTER STUDENTS—DISCUSSION ON SANITARY MATTERS AT THE ACADÉMIE DE MÉDECINE —PROFESSOR DEBOVE ELECTED DEAN OF THE PARIS FACULTY—OVERPRODUCTION OF WINE IN FRANCE—THE NEW PROFESSOR OF OPHTHALMOLOGY.

A NEW restaurant specially destined for students has been started in the Latin quarter. It is a well-known fact that consumption is quite rife amongst students, and it may be due in part to the insufficient food they get in the lower class of restaurants. No spirituous drinks will be allowed in this establishment, though moderate amounts of wine, beer and cider may be called for. Only subscribers are allowed. Twenty-five francs must be paid down in one sum or in monthly instalments. If there is a bonus at the end of the year it will be divided amongst the shareholders according to the number of meals they have ordered. The prices are more moderate than in the celebrated Duval restaurants. Moreover families sending their sons to Paris may pay in advance every month.

The recent case of bubonic plague on the "Sénégal," a steamer which had just left Marseilles, has brought about a good deal of discussion. According to a certain number of physicians who happened to be on board the "Sénégal," the disinfection which takes place at Frioul, the sanitary station of Marseilles, is carried out in a somewhat lax manner. It would seem that a boat, the second officer of which had died of the plague shortly after leaving Port Said, called at the Frioul recently and the passengers were only landed after eight days, given a bath and an approximate disinfection and landed in Marseilles the next day. There are so few drugs to be had in the pharmacy that when a patient has a severe hemorrhage it is found necessary to ask one of the ship doctors for a solution of ergot. Steamers calling at infected ports are not obliged to have serum, or if they have solutions on board four out of six bottles may be in bad condition. Such are a few of the remarks made by physicians who happened to be on board the "Sénégal." At the Académie of Médecine Dr. Buequoy complained bitterly of the condition of the lazaretto, where there is only room for 120, whereas there happened to be 165 passengers on board the "Sénégal." He said that this steamer should have been more thoroughly examined, as there were found the bodies of rats that had died from the plague. There was no serum on board, which was undoubtedly the cause of the death which occurred. Dr. Proust answered Dr. Buequoy's criticisms. He remarked that it was not the fault of the sanitary service, which had given most explicit directions to its agents. At present the precautions carried out are even more rigorous, and if a case of bubonic plague is found the hold of the vessel is disinfected with sulphurous acid. As for a lack of serum on board ship, it is only steamers carrying immigrants that are obliged to take serum. As for the fact that the passengers were not landed, that was because it was thought that the trip might be continued in case the diagnosis of plague was not confirmed. Dr. Proust's speech was a complete justification of all that took place, but, as he is a medical inspector of high standing and one who had just made an inspection in that region, it is not to be wondered at if he supported the sanitary arrangements carried out in this case. Dr. Debove showed that the sanitary taxes brought in almost three times as much as was spent in this department. It is not a lack of money which prevents the carrying out of certain reforms. It was decided to appoint a commission which would see to the carrying out of the necessary reforms.

Dr. Debove has just been elected dean of the Faculty of Medicine. Professor Brouardel, who has served fifteen years in that capacity, sent in his resignation. Professor Pinard at first received the greatest number of votes, but not a sufficient number to be nominated. Then Dr. Debove, who had at first refused to be a candidate, accepted on certain conditions and was elected by a large majority.

The new law, by which the duties and taxes on wines and hygienic drinks were abolished, has not brought about the result which was expected. Neither the Government nor the hygienists are satisfied. It had been thought that by decreasing the price of wine the poorer classes of the population would drink less spirituous liquors. The tax on spirits has brought in less than usual, but this is perhaps due to the fact that the wine sellers had laid in a large stock of alcoholic beverages before the law took effect. As for the wine growers, they are complaining, though the amount of wine drunk has increased by 6,000,000 hectoliters. The trouble lies in the overproduction of wine, due to the recent establishment of vineyards producing a large quantity of inferior grades. The annual consumption of wine in France is about 42,000,000 hectoliters; 65,000,000 were produced in 1900, and 55,000,000 in 1901. This overproduction will continue for several years, and it is hard to say what can be done with this enormous quantity of wine.

Professor de Lapersonne, who has succeeded Panas

as professor of ophthalmology at the Hôtel Dieu, delivered his first lecture on November 10th. Dr. de Lapersonne was dean of the Faculty of Lille until he was given this position.

German.

BOTTINI'S OPERATION—VESICAL CALCULI—EXAMINATION OF THE KIDNEYS.

SCHLAGINTWEIT (Munich), at the Seventy-third Congress of German Naturalists and Physicians, held in Hamburg from September 22 to 28, 1901, read before the Section on Surgery a critique on Bottini's operation, founded on one hundred and fifty experiments and eighty-two preparations of prostatic hypertrophy, collected by Guyon in the Necker Hospital at Paris. He said in part that the early publication of the results aroused doubt as to the adequacy of the operation. This has lately changed, however, owing to the investigations of Freudenberg and others who have established a definite standard of comparison as to results. Cure is now understood to mean that no catheter is further necessary, that the urine passes in a free stream and that there is very little residual urine. Such cures occur in fifty to sixty per cent. of all cases. Improvement implies that there is no longer complete retention, less frequent and active urgency, less pain and more general good health. Twenty to thirty per cent. of the patients show improvement. The unimproved range between thirteen and eighteen per cent., the deaths between four and one-half and eight per cent. Permanent and to some degree satisfactory results occur in seventy-five per cent. of all cases. The contra-indications of the operation are severe nephritis, pyelitis, purulent cystitis and marasmus. Distention of the bladder is not an absolute contra-indication because muscular power soon returns after the operation. The accidents of the operation are bending of the red-hot blade from uncertain handling of the instrument, burning out of the blade and short-circuiting of the current. On account of the latter, the direct current with transformers must be used. The sequelæ of the operation are fever for a few days, especially with purulent inflammation of the urinary tract, secondary bleeding from the casting off of the scab as early as the fourth day and as late as the twentieth day, thromboses and pneumonia. In addition to a delicate handling of the instrument, care must be exercised with special reference to the immediate results, the depth of the narcosis, the possibility of a repetition of the operation and brief confinement to bed for from two to three days. In spite of all objections, von Frisch states that its results are so favorable that no other operation can be compared to the Bottini in treating prostatic hypertrophy. The operation has had comparatively little popularity among genito-urinary surgeons on account of its uncertainty, of the impossibility of knowing the basis of the ultimate success or failure, of the few autopsies recorded after it and of the lack of material, especially in Germany, for the study of good specimens of prostatic hypertrophy. The principle of the operation consists in burning V-shaped channels half an inch deep in the parenchyma of the gland, which after the shedding of the scab tend to deepen without any spreading. Secondary atrophy of the gland does not occur. The mechanical effect of the operation is the reason for believing that the whole matter of prostatic hypertrophy, with all its evil consequences, depends entirely upon a mechanical hindering of the outflow of the urine. The whole value of the operation depends upon the answer to this cardinal question, in which direction, in what number, to what length, and in what serial arrangement must the cuts be made in a given case? Most of the authors give commonplace rules on these points, but none which is universally available. The operator must, however, know the exact anatomical and topographical grounds upon which his cuts shall be based. The technic of the operation is very important. After the introduction of a stiff, straight instrument, like the early designs of Bottini, the gland is no longer normal; its position, condition, relation of the middle lobes, parenchyma and capsule are all changed on acount of the forceful stretching into a straight line of the deformed urethra by the shaft of the instrument. The degree of these changes depends, of course, upon that of the original pathological condition. The pathological arrangement of the gland must be carefully studied before the first or any of the subsequent cuts are made, so that the viscus shall be changed as little as possible. During the operation, therefore, the so-called "typical seizure" of the gland should be absolutely ignored. Cystoscopy should be brought in to determine and describe the features of the gland and the number and the length of the cuts and so far as possible their relation. A combined incision and cystoscopic instrument is too thick and its blade penetrates too little and too short a distance to give any guarantee of efficient work. Bleeding, moreover, is very apt to obscure the operative field and render the cystoscopy valueless. The writer's own method of proceeding is the following: The bladder is filled with sterilized air, explored with a bougie-à-boule, palpated through the rectum and inspected with the cystoscope. The internal orifice of the urethra is mapped out by the finger in the rectum and the exposed cold blade of the instrument. Great delicacy and care must be exercised at this point. The blade is not hooked into the gland, but simply brought down to the end of the urethra within reach of the finger. This mapping-out with the aid of the cystoscope is plotted on a chart which is before the surgeon during the operation. The manifest aid of such a chart needs no further discussion. All the old and new methods of determining the length, number, direction and relation of the cuts leave the following points still unsettled: (1) The length of the cuts in each direction; (2) the direction of the cuts posteriorly; (3) the direction of the cuts toward the side, which must not, of course, be below the horizontal plane of the gland; (4) it is impossible to determine the number of cuts, especially those to the front and to the side above the level of the horizontal plane in every case. Perhaps measuring the angles between the shaft of the instrument and the symphysis pubis and a study of the transverse section at different levels of hypertrophied prostates will permit this question to be settled within definite limits. The author closes with the dictum that beyond question this operation will in time be brought within the same definite limits of procedure as have been in the past and the present laid down for lithotripsy. The operation will then no longer be a surgical curiosity but a definite means of treatment.

ZUCKERKANDL (Vienna) gave his deductions from one hundred and fifty operations for stone in the bladder. Of these one hundred and nine were lithotripsies, one a perineal lithotripsy and thirty-seven suprapubic cystotomies. The mortality ranged from 3.06 per cent. for lithotripsy to 13.03 per cent. for cystotomy. Relapses were equally frequent in both methods. On account of the dangers of suprapublic cystotomy, clearly stated in literature, its prolonged after-treatment, and its many complications at the wound and even after the full healing of the wound, Zuckerkandl believes that it should be abandoned as far as possible. He also considers that perineal lithotripsy is a step forward and

should be substituted for suprapubic cystotomy in the majority of cases. The injury of the urethra in this operation, if skilfully limited, is rather an advantage, because it affords better drainage of the bladder. Lithotripsy is the operation of choice and, in fact, should always be done when the stone is not too large for the instrument to seize. In such a case the perineal method is indicated and also when the urethra is impassable to the straight instrument through prostatic hypertrophy, stricture or urethral calculi, and the completion of the lithotripsy is thereby rendered impossible or when large fragments remain and resist further crushing. Suprapubic cystotomy is applicable to stones which fill the whole bladder or which, on account of their large size, are pocketed in a diverticulum or in a deep fundus, to incapsulated stones, to stones in the ureters or at the junction of the ureter with the bladder, to stones about foreign bodies and for complications of stone and new growth of the bladder, and finally to the purpose of establishing a fistula.

CASPER (Berlin) stated the results of further investigation into the question of examination of the function of the kidney by the method proposed by Richter and himself. Richter's method consists, briefly, in collecting separately at the same time the urine from both kidneys and examining it. While albumin, renal elements, white and red blood-cells, casts, micro-organisms, etc., are indications of the anatomical condition of the kidneys, the functional power of each kidney can be determined by comparing the total amount of nitrogen excreted, of sugar artificially produced by the injection of phloridzin, and the freezing-point of the urine in each separate specimen. In health these three elements are alike on both sides. In disease they differ, the kidney which is the seat of the disease producing less of each. After numerous experiments he has arrived at the opinion that whenever we are treating cases of abdominal surgery, with difficult differential diagnoses, such examinations are both advisable and necessary.

POSSIBLE CURATIVE EFFECTS OF THE NEW ELEMENT RADIUM.

To the Editor of the MEDICAL NEWS:

DEAR SIR: A few days ago appeared in the papers an account of an Atlanta man who had been cured of a cancerous growth by the use of the cathode ray. Whether or not the curative effects of this method of treatment have been fully proved, it certainly is a fact that there has been considerable experimenting along this line, and, according to the reports of many of the experimenters, there has been in some cases at least, an encouraging amount of success.

It would be a matter of much interest if experiments of a similar kind could be carried on with the recently-discovered element radium. The properties of this element, as described in recent numbers of the *Comptes Rendus,* are so remarkable and are so similar to those of the cathode ray that it seems probable it could accomplish all that the latter could accomplish and, perhaps more. Moreover, the radium, if found effective, could be applied in a most convenient form. At the present time the new element is extremely rare and correspondingly costly; but, should the demand for it arise, it cannot be doubted that the supply would be found to increase.

Henri Becquerel, the eminent French physicist and discoverer of the peculiar rays that bear his name, describes the experience of himself and M. Curie, who has the honor of having discovered the new element. M. Curie allowed the rays ordinarily emitted by radium to pass through a sheet of gutta-percha and act on his skin for ten hours, the specimen of material used being comparatively impure. The skin soon reddened and presented all the appearances of a burn. At the end of several days the redness had very materially increased in intensity and the tissue broke away. It was about six weeks before healing had fairly started and ten days later the wound was still open.

Becquerel himself had an accidental experience of the same kind and one equally unpleasant. In transporting a few decigrams of a very pure radium chloride he placed the material in his vest pocket. The radium chloride was in a sealed glass tube and this was wrapped in paper and placed in a cardboard box. It was on the 3d and 4th of April that he carried the material, which remained in his pocket for a total time of not far from six hours. In order to affect the underlying skin it was necessary for the rays to traverse the glass of which the tube consisted, the paper wrapper enveloping it, the cardboard of the box, and several thicknesses of cloth. Yet on the 13th of April a red spot appeared on the skin immediately under the place where the active material had rested, a spot, too, that was the same shape and size as the tube containing the radium. The affected place soon developed all the outward appearances of a severe burn and forty-nine days elapsed before it had healed. As an indication of the strength of this action, it should be mentioned that, while the original wound was under treatment, a second and less severe one made its appearance opposite another part of the same pocket, showing that for a short time the small package must have been in a new position.

Madame Curie, who has been associated with her husband in the investigation of this substance, was burned in a quite similar manner, though less severely, the rays beng compelled to traverse the thin walls of a metal box in which a sealed tube had been placed. The purified radium is so active in its effects on the skin that the experimenters frequently found it inconvenient to handle the tubes or capsules containing the material, the fingers being burned.

If the new element has effects so remarkable when applied to the skin, might it not be found to have all the effects of the X-ray? And might it not be possible that these powers could be utilized in medicine? If the effects should prove desirable, it would certainly be far easier to use this remedy, for it could be applied directly for any length of time and in any desired strength.

Chemical Department, University of California.

SOCIETY PROCEEDINGS.

NEW YORK COUNTY MEDICAL SOCIETY.

Stated Meeting, Held November 25, 1901.

The President, George B. Fowler, M.D., in the Chair.

Address of the Retiring President.—Dr. Fowler reviewed some of the work of the County Medical Society since its formation nearly a century ago. He dwelt especially on all that the New York State Medical Society, whose origin was due to the New York County Society, had done to secure organization among medical men in this country. He said that by an unfortunate misunderstanding the New York County and State Societies had ceased to exercise their proper functions as integral parts of the American Medical Association, but that the

principles of which they had been the exponents had undoubtedly proved themselves the true ones that must guide medical action. It seemed to Dr. Fowler then that the time was ripe to hope for union between the New York State Medical Society and the American Medical Association, and he expressed the wish that the new administration would see such a union effected.

Address of the President-Elect.—Dr. Frank Van Fleet, the incoming president, said that for the ninety-sixth time the County Medical Society of New York was listening to the annual address of a new president. Despite the long years of service of the Society to the profession of the State and of the country, a lamentable misapprehension keeps the New York State Society from association with the National body of physicians in the country. While the friendliest feeling exists between the vast majority of the members of the New York County Medical Society and the New York County Medical Association, the best proof of which is the fact that 67 per cent. of the members of the New York County Medical Association are also members of the New York County Medical Society, still the two organizations exist and the fact of their dual existence lessens their usefulness and influence. (We print in this week's issue the complete address of Dr. Van Fleet.)

Committee on Reconciliation.—After the President's address Dr. D. St. John Roosa offered a resolution to the effect that a committee of five should be appointed by the president of the New York County Medical Society to confer with a similar committee from the New York County Medical Association for the purpose of discussing the ways and means of reconciliation between the two bodies so as to bring the matter formally before the New York State Medical Society at its next meeting in Albany. This resolution was adopted without a dissenting voice.

Prophylaxis of Venereal Diseases.—Dr. Prince A. Morrow, Chairman of the Committee of Seven appointed last February by the President of the New York County Medical Society to discuss the subject of the prophylaxis of venereal diseases in New York City, then read an abstract of its report. The full report appears in this week's issue of the MEDICAL NEWS.

Regulation of Prostitutes.—In the discussion Dr. Ferdinand Valentine said that with regard to the regulation of prostitution and the consequent diminution and prophylaxis of venereal diseases, the main difficulty is the state of public opinion with regard to these questions. The public absolutely refuses to listen to medical warnings with regard to the dangers involved, and even refuses to concede the existence of the social and physical evil, at least to anything like the extent to which they really exist in our midst. It is not difficult to propose remedies that will surely be effective, and the Committee has certainly been thoroughly conservative and eminently judicious in their discussion of the possible means of regulation. For this the medical profession owes them sincere thanks.

Segregation as a Remedy.—The present condition of prostitution has certain indications that should be of service for its regulation. Naturally, prostitutes walk in certain quarters of the city and thus point out that their aggregation in certain places represents the next possible step in the regulation of the evil. This segregation should be either in districts or, as the Committee suggests, in domiciles. In order that this method should be efficacious the districts or houses selected for occupation by prostitutes should be rigorously policed and should be kept constantly under the eye of the higher authorities so as to prevent the evils that might flow from police complacency with regard to vice for interested reasons. As is the rule in certain countries in Europe, visitors to public houses of prostitution should be warned of the character of the house they are about to enter. Each visitor should be provided with an official printed circular pointing out the dangers of venereal diseases and the most approved method for their prevention. At least then the public duty will have been done in providing proper warning of evils of which the visitors to such institutions may not have proper knowledge.

Education of Public.—In addition to the direct and immediate instruction furnished by circulars, the medical profession should make its influence felt for the education of the public with regard to the dangers of venereal disease and especially their presence widespread in our midst. As a matter of fact, at the present moment the proper recognition of these conditions by the general public is extremely meager. Knowledge means more for the protection especially of the young than any other possible precaution that can be taken. The evils under consideration are inevitable, but the exercise of proper safeguards can make them as little effective for evil as possible. The medical profession owes it as a duty to itself and to the public to make perfectly clear the present condition of affairs with regard to these diseases.

Prize Essay on Venereal Diseases.—Dr. S. Adolph Knopf said that in the present battle against tuberculosis the German Government, by the advice of some of the best and most practical medical men in the world, had decided that one of the most opportune and promising methods of teaching the public the necessity and manner of guarding against the spread of tuberculosis was to publish an essay that gave them the necessary information in a complete yet thoroughly popular and intelligible manner. This essay had been obtained as the result of a prize competition in the matter offered by the German Society for the Prevention of Tuberculosis and after the decision for the prize had been distributed widely throughout the German Empire. Dr. Knopf thinks that this same method would prove efficacious for the prophylaxis of venereal diseases. The problem presented by the two sets of cases are very nearly similar in the factors that make them up. Dr. Knopf offered a resolution that the New York County Medical Society take into consideration this question of giving a prize for a popular essay on the avoidance of venereal diseases. This essay could after the prize decision be distributed widely and so form the basis for well-grounded knowledge in the public mind with regard to this important question. This resolution was adopted and was referred by the President of the Society to a committee for due consideration and report.

Candid Medical Declaration.—Dr. Lapowski said that the most important announcement that the medical profession could make in the matter of a venereal disease, in order to give the public true ideas with regard to them, was the candid declaration that physicians are practically not able to say that they can ever cure them. The present laxity of public opinion with regard to the danger of vene-

real diseases is due to the fact that the public has an overconfidence in power of physicians to heal them. One is never able to say that a case of syphilis is cured. One can relieve the symptoms of the initial stages of the disease and can give the patient some confidence as to his condition, but one can never assure him that he will not have relapses, and, after relapses have occurred and have seemingly been successfuly treated by remedies, no assurance can be given against their future recurrence. With regard to gonorrhea, one is almost in the same condition. One knows when a gonorrhea begins, according to the expression of a famous French venereal specialist of half a century ago, but one cannot say when it will end. Here, too, one is able to relieve symptoms and sometimes even to effect a cure; but in any given case one can not be sure of bringing about this eminently-desirable result. An elaborate system of police regulation of prostitution has ben instituted at Breslau under the immediate direction of Neisser, the discoverer of the gonococcus. There the prostitutes are thoroughly examined at stated intervals, not by ordinary inspection alone, but by means of the microscope. The result of this rigorous examination has been to beget overconfidence in the general public as to their protection against gonorrhea in intercourse with the prostitutes who are under municipal regulation. The statistics of Breslau show that there is a greater amount of gonorrhea to the thousand of population than in any city in Europe. This may be partly due to the fact that the statistics of gonorrhea are better kept at Breslau than elsewhere, but it is also undoubtedly due to the false confidence begotten of faith in legal regulation. With regard to the young, particularly, Dr. Lapowski believes that they should be sedulously warned of the dangers of venereal disease and of the possibilities of their easy contraction. Dr. Lapowski himself will never forget the last word to his class of one of his old professors at Warsaw: "Remember that one cannot be too careful with regard to the contraction of venereal disease. Slight and innocent contact may have serious results. Never kiss a young woman until you have thoroughly assured yourself that the glands at the back of her neck are not swollen."

SOCIETY OF DERMATOLOGY AND GENITO-URINARY SURGERY OF NEW YORK.

Stated Meeting, Held November 8, 1901.

The President, R. H. Greene, M.D., in the Chair.

Tuberculosis of the Testicle.—Dr. H. H. Morton reported a case of tuberculous testicle, with the following history: W. P., aged 49 years, plumber; father died of phthisis; patient has always been in good health until six weeks ago when the present trouble began. He vaulted over an area railing six or seven steps high, but for the moment did not experience any pain. The second day afterwards his testicle began to enlarge and feel very painful, reaching its maximum size in about two days. Then it remained stationary for four weeks. Two weeks ago it began to soften at one point. The pain which had been present all the time continued. An examination showed that the right testicle was enlarged, it was adherent to the scrotum and soft at one point. The cord was enlarged and thickened, the seminal vesicles and prostate as felt *per rectum* were normal. Operation was performed on October 12th, consisting in castration, and at the same time circumcision for elongated and phimotic prepuce. On removal the testicle was found to be riddled with small abscesses filled with pus and detritus.

Dr. Morton regards as the interesting feature of this case the very unusual history which the patient gave and which would lead one to suspect a traumatic hematocele occasioned by a "snap the whip" action of the cremaster muscle, rupturing some of the testicular veins, instead of an uncomplicated but very rapid form of tuberculous infiltration.

Dr. Ramon Guiteras, in discussing the case, said that some time ago he operated upon a patient whose condition was the same as that which Dr. Morton describes. The patient had received six months previously a blow by falling or jumping, after which his scrotum had become ecchymosed, swollen, and painful to the touch. The swelling decreased, and left a hard, smooth, solid tumor which resembled that of hematocele. An incision was made through a dense, thickened tunica, and two ounces of prune-juice-colored fluid escaped. The testis and epididymis were then seen to have a lardaceous look, and to be enlarged. The organs were evidently diseased, although the induration was general and there was no nodular formation. He removed the testis and submitted it to a pathologist, who reported it to be tuberculous. It must be remembered that, although tuberculosis of the testis usually shows itself in nodules which later on break down and suppurate, such testes are sometimes perfectly smooth. He recalled a case in his service at the City Hospital, that of a man, forty-five years of age, who had one testis removed, presumably for tuberculosis, and who had entered the hospital on acount of an abscess in the remaining testicle. Examination showed the testicle to be enlarged, hard, ovoid in shape, and perfectly smooth. The epididymis was stretched out over it, and there was a sinus running up into its globus minor. The patient was told that the gland would not be removed unless absolutely necessary. Dr. Guiteras intended to open up the sinus, curette it, cauterize it with carbolic acid, etc. Accordingly, he enlarged the opening and began to curette. A large amount of tuberculous tissue was removed and the sinus was found to communicate with the testis proper. Continuing to remove tuberculous tissue, he found, to his surprise, that the entire cavity of the gland had been removed, and nothing but the capsule of the testis had remained. The capsule did not collapse, but retained its shape like a shell. What had seemed to be a smooth, round tumor, hard like a syphilitic testicle, was in reality a shell full of tuberculous detritus. The whole gland was, of course, removed later on.

Cancer of Testis.—Dr. Morton also reported a case of cancer of the testicle, with operation. J. S., artist, aged thirty-nine years; father died of old age; mother, of pulmonary tuberculosis; the patient had never had any venereal disease. One year ago noted growth in testicle as large as a bean. This grew rapidly larger and attained its full size in two weeks. During all this time patient had no pain until six weeks ago, when some pain was experienced in the back at night, but none during the day while up and about. Patient has become emaciated during the last three months, particularly in the last five weeks, losing about forty pounds in three months. On examination lungs and abdomen were found normal. The testicle on palpation was smooth, oval, but showed a distinct fluctuation; the spermatic cord was not

enlarged. On testing the translucency with a lighted candle and a tube the tumor was found to be opaque. On aspirating with a hypodermic exploring needle a few drops of blood and bloody serum were withdrawn. After making an incision through the scrotum and the testicular covering, the tunica vaginalis was found to contain only one to two drams of fluid, but the whole body of the testicle was enlarged by a soft fleshy growth. The spermatic cord was not thickened and on this account one of the important diagnostic signs of malignant disease of the testicle was not available. Dr. Morton thinks that this case emphasizes the difficulty of making a diagnosis in certain cases of testicular new growth. In the present instance a hydrocele, with thick walls and inspissated and bloody contents, was supposed to be present, until an incision proved the solid character of the tumor. Specimens of both cases were presented to the society.

A New Urethroscope.—Dr. F. Cabot presented a new urethroscope. According to his opinion the source of light used in urethroscopy should be placed at the distal end of the tube, as is the case in the instrument devised by Dr. C. H. Chetwood. In Dr. Cabot's instrument there are some main and some minor improvements. In the first place, the lumen of the tube remains unobstructed by the lamp and its holder, which has been placed in a chamber. This chamber protrudes somewhat, but very slightly, into the lumen of the tube, so as not to interfere in any way with the inspection or the free use of applicators. Furthermore, the chamber increases the size of the tubes only two numbers, as measured by the French scale. The lamp and connecting wires are sealed within the holder, so that they can be washed and even boiled without being

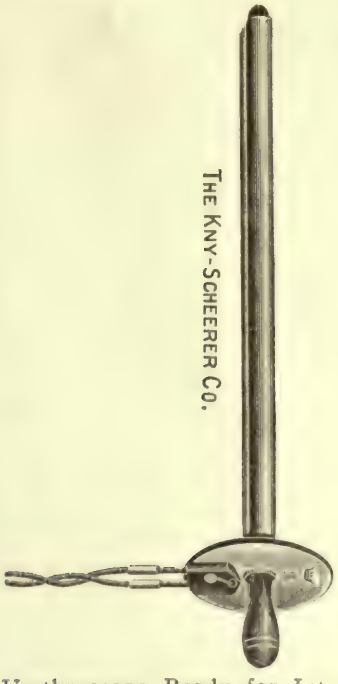

Fig. 1. Urethroscope Ready for Introduction.

injured thereby. A great advantage of the instrument is that the obturator and lamp are both left in place when the instrument is introduced into the urethra, so that after the withdrawal of the obturator an inspection and application can be made at once by simply turning on the electric current. In addition to these points another improvement has been made by doing away with the switch usually

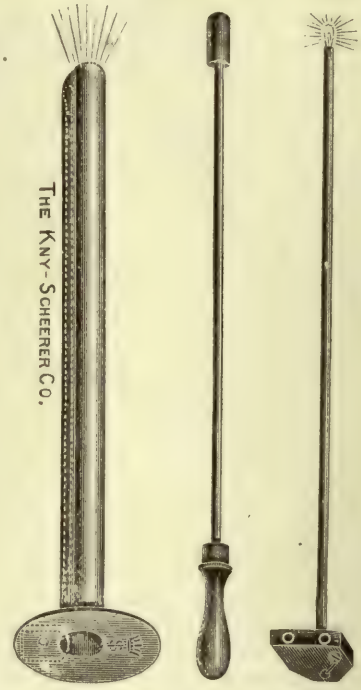

FIG. 2. *a*, Light-carrier; *b*, Obturator; *c*, tube.

placed on the lamp holder, the turning on and the regulation of the light being effected by the rheostat of the battery.

Cystitis Due to Mixed Infection.—Dr. Bierhoff reported a case of cystitis due to a mixed infection of the gonococcus and bacterium coli. The patient was a woman, aged twenty-one years, who had been ill four or five weeks with severe symptoms referable to the bladder. The condition began with increased frequency of urination accompanied by more or less burning and tenesmus, these symptoms steadily growing more intense. Two weeks ago she came under the care of Dr. McBarron, who employed vesical irrigation, which was followed by some relief, but internal medication had to be substituted for this method of treatment, because the catheter caused considerable pain. She has become much emaciated and has a slight temperature. Examination of the urine showed pus, epithelium and staphylococci, and the condition was regarded as being of renal origin. Of late the urine has been decidedly purulent and the patient has been confined to bed. She has to urinate about every fifteen minutes day and night, and the act is accompanied by great tenesmus and burning. No blood has been passed. Both kidneys were easily palpable, slightly mobile, the right more so than the left; neither of them is enlarged nor tender. A purulent urethral and vaginal discharge and some tenderness in the vagina over the neck of the bladder are present. Introduction of the catheter is exquisitely painful. A small quantity of very turbid urine was withdrawn by the catheter. A one-per-cent. solution of cocaine injected into the bladder did not relieve the pain sufficiently to permit irrigation. The patient was then deeply anesthetized, but only 70 to 75 c.cm. of fluid were tolerated, a greater quantity being expelled at

once. Cystoscopical examination revealed marked inflammation over the entire sphincteral region and trigone and the entire mucous membrane showed an irregular, roughened surface with a folded and very reddish appearance. Both ureteral orifices were large and pouting, the left, together with its surrounding membrane, appeared to be more inflamed than the right. The ureteral catheter withdrew clear urine from right kidney which appeared to act very freely; on the left side the catheter was arrested at a point 5 mm. from the ureteral orifice. A sound introduced afterward was likewise arrested. The diagnosis made was cystitis suppurativa acida acuta, presumably of gonorrheal origin. The treatment consisted in urethral and vesical irrigations with a one-per-cent. boric-acid solution without catheter, followed by injections into the bladder of one-fourth to one-per-cent. nitrate of silver solution. The vagina was irrigated with protargol solution, one-half to one per cent., and then packed with gauze strips saturated with five-per-cent. protargol in glycerin. Morphine was given *per rectum*. The patient made a slow but complete recovery. Examination of the urine withdrawn by means of a sterile catheter showed the presence of pus with vesical epithelium and two varieties of microorganism, a short, plump diplobacillus, presumably bacterium coli and typical intracellular and extracellular gonococci which reacted positively to Gram's stain. Smears from the urethra and vagina revealed the presence of intercellular and extracellular gonococci and colon bacilli in the former and many varieties of micro-organisms, but no gonococci, in the latter.

Mycosis Fungoides.—Dr. Lapowski presented a case of mycosis fungoides in its prefungoid state. The patient was a nurse, forty-two years of age, born in Ireland, who had been in good health up to her twenty-ninth year, when she had an attack of quinsy and rheumatic fever lasting two months. Eight years ago she contracted diphtheria and a year later an eruption developed on her body and still exists in the same form. The first patches appeared on the right arm, gradually spreading over the body and affecting principally the flexor and also part of the extensor surface of both upper and lower extremities, the neck, trunk, abdomen, sacral region and buttocks. The palms and soles have been and are free from the eruption. The scalp has the appearance of a pityriasis sicca, and on both cheeks several dry, eczematous patches are present. The size of the patches ranges from that of a pea to a half dollar, of round or oval shape, sharply defined and only very slightly projecting above the surface of the skin. They are brownish-red in color, discrete and isolated. The surface is dry, slightly scaly. The skin folds are well marked, some of them slightly infiltrated, giving a peculiar feeling of hardness when taken between the fingers. The patches extend peripherally, but do not clear up in the center; glands, mucous membranes, nails and hair are in normal conditon. There is absolutely no change in the location, extension and color of the lesions since the patient was first seen five years ago, except that some patches have disappeared. No subjective symptoms of any kind are present. As regards treatment a great many remedies have been employed in the form of ointments and plasters, and iron, arsenic, strychnine, iodide of potash, thyroid extract, etc., have been given without benefit. Only the application of Churchill's tincture of iodine produced a marked but temporary improvement, the patches disappearing and leaving dark-brown marks, but soon reappeared without responding again to the tincture of iodine.

Dr. Morton said that the patches resembled very much those of squamous eczema as they are seen in persons with a pale, anemic integument.

Dr. Goldenberg suggested that the case might belong to that class of skin diseases described as leucemia cutis or lymphodermia. An examination of the blood should therefore be made. The history of the case is strongly in favor of mycosis fungoides, still he would expect a little more infiltration of the patches and the presence of itching.

Dr. Leviseur said that in two cases of mycosis fungoides he had observed the sudden disappearance of some of the lesions in what seemed to be an erratic manner and entirely independent from treatment, as in Dr. Lapowski's case, and he considers it one of the characteristics of this affection. Even when the disease is in its fungating stage some of the well-developed tumors suddenly disappear without leaving a trace, the skin, of course, never being entirely free from lesions.

On account of the fatal character of the disease an early diagnosis of the erythematous or eczematous stage is of the utmost importance.

BOOK REVIEWS.

A TEXT-BOOK OF THE PRACTICE OF MEDICINE. By JAMES M. ANDERS, M.D., Ph.D., LL.D., Professor of the Practice of Medicine and of Clinical Medicine in the Medico-Chirurgical College; Attending Physician to the Medico-Chirurgical and Samaritan Hospital, Philadelphia. Fifth Edition. W. B. Saunders and Co.: Philadelphia and London.

A TEXT-BOOK of medicine that runs rapidly through several large editions needs no praise, and for our opinion of the present work we refer the reader to our favorable comments on former editions. The more important changes noted are the thorough revision of the infectious diseases, the bringing up to date of the section on nervous diseases, and the addition to the work of some new articles, such as fatty infiltration of the heart, streptococcus pneumonia, etc. Under malaria and yellow fever, brief but sufficient résumés are given of what has been done to establish the transmission of these diseases by the mosquito. Splenic anemia occupies a section, although the author holds that many of the cases are really pernicious anemia, or secondary anemia with splenic enlargement.

A TEXT-BOOK OF OBSTETRICS. By BARTON COOKE HIRST, M.D., Professor of Obstetrics in the University of Pennsylvania; Gynecologist to the Howard, the Orthopedic, and the Philadelphia Hospitals, etc. Third Edition. W. B. Saunders and Co.: Philadelphia and London.

THE new idea of substituting photographs for text is followed with success to a marked degree in this work, yet there is excellent and ample reading-matter for the elucidation of the subject. The nature of perineal tears, the molding of the head, the positions occupied by the fetus, the mechanism of labor, the method of applying forceps, and the performance of version become clear to the mind on studying these pictures, in a way impossible from the most elaborate text. Deformities and obstructions to labor are also well illustrated. The author has had the good judgment, in this practical work, to make his chapters on anatomy, embryology

and mere curiosities brief and to the point. He has considered and dwelt upon the problems which confront the general practitioner at every turn, and in so doing has prepared a book eminently fit for students as well. The diseases of the new-born are treated of rather too briefly. In the treatment of asphyxia, the useful method of artificial respiration by alternate doubling up the body to deflate the chest and hyperextension to inflate it is not mentioned.

On Paralysis Agitans. With an Account of the Clinical Features of Other Forms of Tremor. By R. T. Williamson, M.D. (Lond.), F.R.C.P., Physician to the Ancoats Hospital, Manchester, and Assistant Lecturer on Medicine, Owens College. Sherratt & Hughes, Manchester.

This little book contains a good résumé of our present knowledge of paralysis agitans. It consists mainly of a clinical study of the disease in its somewhat varying forms. Of the pathology of the disease the author confesses that "it may be truly said that as yet we see through a glass darkly." As a matter of fact, very little has been added to our knowledge of the disease since Parkinson originally described it in England in 1817. Dr. Williamson's idea is, by bringing all of our present knowledge of the disease into small compass, to call renewed attention to it and so lead, perhaps, to active interest that shall broaden our views with regard to the disease. The study of other forms of tremor makes the book especially interesting to the general practitioner.

The International Clinics. Volume III., Eleventh Series. A Quarterly of Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose and Throat, and Other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession Throughout the World. Edited by Henry M. Cattell, A.M., M.D. J. B. Lippincott Company, Philadelphia.

The present volume of the "International Clinics" has for its opening article a thorough exposition of the methods in phototherapy invented and improved by Professor Finsen of Copenhagen. This article contains a series of illustrations of the results of that treatment, especially as applied to lupus vulgaris and cutaneous epithelioma. It is well known how much has been accomplished by Finsen's therapeutic methods. This article is by Valdemar Bie, Professor Finsen's laboratory assistant in the Finsen Institute. The technic of the employment of concentrated artificial light is the subject especially insisted on.

This volume contains in addition a series of articles on appendicitis. There is a discussion of the prognosis of appendicitis by Dr. Tubby of London; a description of selected cases of appendicitis by Dr. Deaver of Philadelphia; the surgical treatment of appendicitis by A. Routier of Paris; double nephropexy and inversion of the vermiform appendix by George M. Edebohls of New York, besides an excellent article on some acute affections of the gall-bladder and its associated ducts by Dr. Howard Lilienthal of New York, in which the differential diagnosis of biliary and appendiceal affections receives very full and practical discussion.

The section on neurology is of special interest in this volume. There is an article by Professor Arnold Pick of Prague on areas of softening in both cerebral hemispheres; an article on hereditary cerebellar ataxia and nocturnal epilepsy by Dr. D. R. Brower of Chicago; an article on the localization of nervous lesions by Dr. Alfred Wiener of New York, and an article on cerebellar degeneration due to intestinal intoxication by Augusto Murray of Bologna, Italy. This last article introduces a comparatively new idea into neurology, namely, the question of the degeneration of nervous tissue as the result of auto-intoxication, somewhat in the same way that the liver and kidneys seem to degenerate from this cause.

Libertinism and Marriage. By Louis Jullien, M.D., Laureate of the French Academy of Medicine, Surgeon to St. Lazare Hospital, Paris, and Professor Agrégé of the University of Paris. Translated by R. B. Douglas. Philadelphia: F. A. Davis Company.

This little book is a popular exposition of certain of the evils that modern medical science has shown to be concomitant to venereal diseases. Professor Jullien has had a large experience with these diseases in the St. Lazare Hospital. This is the woman's prison of Paris, where women under the control of the police are detained when ill. The author is especially competent to write on this subject. It is only of late years that the realization of some of the dangers that he points out has come even to the medical profession. In our large cities we are coming to appreciate more and more how necessary are the warnings that he gives in this important matter. Much more of the sterility of modern marriage is due to previous venereal disease than has been admitted, and the question is an extremely important one from many aspects. The book is written in a matter-of-fact French style that appears somewhat startling when translated almost literally into English. It can scarcely fail, however, to be of great service in this country.

Transactions of the American Electro-Therapeutic Association. Ninth and Tenth Annual Meetings. Philadelphia: F. A. Davis Company.

This volume contains in handy form the most recent conclusions of those who are engaged in the practical application of electricity to the diagnosis and cure of disease. A number of the papers are distinct contributions to the subject of electro-therapeutics from medical men who are most occupied with this subject. The ordinary practitioner is prone to think that greater claims are made by specialists in electro-therapeutics for the effect of electricity upon disease than are justified by the results obtained. This objection may hold perhaps with regard to some of the papers contained in this volume. For those, however, who are interested in knowing the claims advanced for electro-therapeutics it can scarcely fail to be of great interest.

Dr. Betton-Massey's articles on the treatment of cancer by the Massey method and the cataphoric treatment of cancer are of this class. Dr. William Morton's article on spark-gap currents, and Dr. Snow's article on the Morton wave current treat of special phases of applied electricity with regard to which original documents are always of more than ordinary interest. Three articles on the application of electricity to neurasthenia by Dr. Francis B. Bishop, Dr. Daniel R. Brower and Dr. William B. Benham Snow deserve attentive reading, because they represent the phase of medical application of electricity which is most generally conceded to be useful. The volume as a whole is a distinct addition to American medical literature and a definite assurance that no branch of medical science, however abstruse, is to be neglected in any important feature by America medical men.

The International System of Electro-Therapeutics. Edited by Horace R. Bigelow, M.D., and G. Betton Massey, M.D. Philadelphia: F. A. Davis Company.

Electro-Therapeutics remains one of the most alluring and one of the least satisfactory chapters in mod-

ern therapeutics. Recent advances in applied industrial electricity have made medical interest in the subject greater than ever. As the editor says in the preface, "At a time when remarkable and even spectacular progress is being made in the industrial applications of electrical force, each advance necessarily the final effort of a specialist within his special department of physics, it is but reasonable that physicians should also demand a treatment at first hand of the many questions involved in scientific electro-therapeutics rather than mere compends written by partial cultivators of the field."

The fact that the second edition of this book should be called for within a few years shows how extensive is the interest in the subject. The present volume well represents the status of electro-therapeutics as at present applied by men who have had most experience in medical applied electricity.

The section devoted to the application of electricity to gynecology and obstetrics is of most general interest. The first article, on the electrical treatment of fibroid tumors of the uterus, is supplied by Dr. Grand and Dr. Famarque, Assistants at the clinic of the late Dr. Apostoli of Paris. Other articles in this section are by Drs. A. Tripier of Paris, Augustin Goelet of New York, J. H. Kellogg of Battle Creek, Mich., A. Lapthorn Smith of Montreal; and an interesting article on ectopic gestation by Drs. Carter S. Cole and George W. Jarman, revised by Dr. Egbert H. Grandin, also appears.

In the section devoted to diseases of the nervous system, Dr. William J. Morton of New York, in the article on diseases of the spinal cord, gives the usual enthusiastic account of good results in the application of various forms of electricity to organic nervous disease. Unfortunately, the claims thus made are not substantiated by other and less enthusiastic practitioners of electro-therapeutics. Dr. Wm. Leszinsky of New York has a very practical article on the applications of electricity to the treatment of diseases of the peripheral nerves. The contrast between Dr. Morton's sixty pages and Dr. Leszinsky's sixteen, though the latter has a subject in which the application of electricity is surely of great benefit, is at least striking.

With regard to much of the book one is tempted to say that electro-therapeutics is not a little discredited by the overenthusiastic claims of certain specialists who obtain results which frequently lack confirmation at other hands. Within the pages of this volume, however, better than anywhere else in English, at least, can be obtained all that is known and practised, whether successfully or otherwise, in the domain of electro-therapeutics.

A SYSTEM OF PHYSIOLOGIC THERAPEUTICS. A Practical Exposition of the Methods, Other than Drug-giving, Useful in the Prevention of Disease and in the Treatment of the Sick. Edited by SOLOMON SOLIS COHEN, A.M., M.D. Volumes III., IV.—Climatology—Health Resorts—Mineral Springs. By F. PARKES WEBER, M.A., M.D., F.R.C.P. (Lond.). With the Collaboration for America of GUY HINSDALE, A.M., M.D. P. Blakiston's Son & Co., Philadelphia.

DR. COHEN'S idea of a system of therapeutics is further developed in these two volumes, III. and IV. of his series. In Book I. the Principles of Climatotherapy, Ocean Voyages, Mediterranean, European and British health resorts are considered. In Book II., the health resorts of Africa, Asia, Australasia and America, Special Therapeutics and an article on the Hawaiian Islands are presented.

This contribution to therapy, in its convenient form, is especially worthy of earnest commendation. In a country where, and at a time when, far too many books are being published and people are too busy to more than glance at titles, it is a pleasure for the reviewer to be able to say that such and such a volume stands out in distinct relief and is worth the time and the trouble to study. Such is the position of these two volumes. While in many respects they are capable of improvement, yet what shortcomings they do possess are appreciable after all by the specialist in the line and would not be any detriment to the book's value to the general student.

The topic of the treatment of disease by climate is in great need of more careful and accurate handling than has hitherto been accorded it; the works of scientific value bearing on the topic have been all too few and even the best have been greatly restricted in scope. The present volumes fully answer the highest scientific canons of the day, and they cover a field almost coextensive with the civilized globe. In fact, there is so much said about so many places that a just criticism may be made that not enough is said about numerous resorts which enjoy a wide reputation.

The work is especially valuable, by reason of the able collaboration of Dr. Hinsdale, for the American practitioner, as in the second book a complete survey is made of the field of the American health resorts.

The work of the publisher is worthy of special commendation.

THE MEDICAL NEWS VISITING LIST FOR 1902. Lea Brothers & Co., New York and Philadelphia.

FOR sixteen years the MEDICAL NEWS "Visiting List" has been a friend of many. It has been pocket companion, friend, bank record and reminder of engagements.

This year the "Visiting List" comes in substantially the same form. Its reading matter has been carefully revised and its schemes for dentition, alphabetical list of therapeutic hints, directions for examination of the urine, modes of inducing artificial respiration and ligation of arteries, tables of doses, diseases and their remedies, weights and measures and other features, all combine to make this an exceedingly valuable book for the physician's daily round.

Its small size, strong binding and well-proportioned pages make it essential for the record of the many details of practice or business.

DICTIONARY OF PHILOSOPHY AND PSYCHOLOGY. Including Many of the Principal Conceptions of Ethics, Logic, Æsthetics, Philosophy of Religion, Mental Pathology, Anthropology, Biology, Neurology, Physiology, Economics, Political and Social Philosophy, Philology, Physical Science and Education, and Giving a Terminology in English, French, German and Italian. Written by Many Hands and Edited by JAMES MARK BALDWIN, Ph.D., Hon. D.Sc., Hon. LL.D., Stuart Professor in Princeton University. In Three Volumes. Vol. I. New York and London: The Macmillan Company. $5.00.

THIS work is a veritable *index rerum* of science, pure and applied, as well as a dictionary of philosophy and psychology. It is more than a dictionary; it is almost an encyclopedia. For many years it has been in preparation. Dr. Baldwin has had associated with him scholars from almost every seat of learning and he is to be congratulated in this, the first volume, of the enterprise. We recommend it most heartily to all those interested in science. Great pains are manifest in the preparation of the terms relative to positive science, such departments as biology, in which so many important advances have been made in the past few years, being especially complete, and the topics discussed, the modes of spelling, the questions of terminology and of classification have all received attention from scholars

evidently equipped, in the best senses of the word, for such questions.

For students of psychology, neurology and psychiatry, this work makes special appeal in that the terms of these sciences, usually so difficult of translation in different languages, have received very careful consideration by a united board of editors. This feature marks a great step forward for the English student of psychology. Special bibliographies make the work of immense value. No matter what the subject under discussion may be—alphabet, alternating insanity, brain, cleptomania, emotional insanity or language—each has a short bibliography of the most recent and best authors who have discussed these problems.

It is particularly refreshing to find such sharp, terse definitions of terms which in other works are long drawn out and almost impossible of understanding.

The publishers' problems have been well handled and the work is one to recommend from every point of view as an evidence of good workmanship and high scholarship.

MANUAL OF CHEMISTRY. A Guide to Lectures and Laboratory Work for Beginners in Chemistry. A Text-Book Specially Adapted for Students of Medicine, Pharmacy and Dentistry. By W. SIMON, Ph.D., M.D., Professor of Chemistry in the College of Physicians and Surgeons of Baltimore. Seventh Edition. Thoroughly Revised. New York and Philadelphia: Lea Brothers & Co.

WE have had occasion in commenting on previous editions of this work to express the criticism that for the purposes set forth this is one of the best works of its kind. Continued revision has improved it greatly.

In this present revision certain trends in modern-day chemistry have been well and adequately pointed out. Thus, the engaging subject of physical chemistry, with its wealth of new ideas bearing on the electrolytic theories and phenomena, is brought to the attention of the student and the fundamental principles very clearly expounded. Much more might have been added with profit for the student of medicine since medical literature is now bristling with the brilliant results of physico-chemical studies on toxic action, pharmacology, antiseptic action, etc.

The chapters on physiological chemistry have been enlarged and rounded out, thus bringing this fundamental structure of physiology into modern lines for the beginner.

The character of the work from the purely mechanical and artistic standpoints is particularly worthy of commendation.

HUMAN PHYSIOLOGY. Prepared with Special Reference to Students of Medicine. By JOSEPH HOWARD RAYMOND, A.M., M.D., Professor of Physiology and Hygiene in the Long Island College Hospital, and Director of Physiology in the Hoagland Laboratory. Second Edition. Philadelphia: W. B. Saunders & Co.

THE assumption that in the short time allotted to the study of physiology in medical schools students can assimilate only the main facts and principles of the subject is perhaps a justifiable one, and it has led to the production of a number of text-books for students' use of which the volume under consideration is a good example. It is inevitable that in such a book many subjects must be dismissed with less consideration than thoughtful students will demand for them. Prof. Raymond frankly recognizes the deficiencies growing out of his voluntarily-assumed limitations of space in referring those who desire fuller knowledge to the larger works on physiology.

On the whole the author has avoided plunging his readers into difficulty by adhering to a style at once brief and lucid. He does not steer clear of what he calls the more "recondite and abstruse phases" of physiology, however, when he undertakes to dispose of doubtful matters by verbatim quotations from authors holding fundamentally inconsistent views. Thus, in adjacent paragraphs, Gray is made to say that splenectomy is necessarily fatal, while Schäfer is quoted to the effect that the spleen "is in no way essential to the normal nutrition of the body." The citation of clinical histories of cases of cretinism, in the chapter on ductless glands, is in questionable taste. If a similar plan were adhered to throughout the book we should have a work on physiology containing clinical histories and illustrations of cases of renal disease, hepatic disease, and so on without limit. Anatomical Plate III. is very well printed, but, as presumably it is intended to picture normal organs in their proper positions, it would be advisable to represent the greater curvature of the stomach as reaching not quite below the level of the umbilicus. The illustrations are numerous and as a rule useful, and the volume as a whole will serve its purpose well.

BOOKS RECEIVED.

The* MEDICAL NEWS *acknowledges the receipt of the following new publications. Reviews of those possessing special interest for the readers of the* MEDICAL NEWS *will shortly appear.

INTERNATIONAL CLINICS. Edited by Dr. H. W. Cattell. Vol. III. Eleventh Series. 1901. J. B. Lippincott Company, Philadelphia.

A MANUAL OF THE PRACTICE OF MEDICINE. By Dr. F. Taylor. Sixth Edition. 8vo, 1030 pages. Illustrated. P. Blakiston's Son & Co., Philadelphia.

THE ROENTGEN RAYS IN MEDICINE AND SURGERY. By Dr. F. H. Williams. 8vo, 658 pages. Illustrated. The Macmillan Company, New York.

A LABORATORY HAND-BOOK OF URINE ANALYSIS AND PHYSIOLOGICAL CHEMISTRY. By Dr. C. G. L. Wolf. 12mo, 190 pages. Illustrated. W. B. Saunders & Company, Philadelphia and London. $1.25.

THE SURGICAL TREATMENT OF DISFIGUREMENTS AND DEFORMITIES OF THE FACE. By Dr. John B. Roberts. Second Edition. Brochure, 72 pages. Illustrated. The Philadelphia Medical Publishing Co.

ON PARALYSIS AGITANS WITH AN ACCOUNT OF THE CLINICAL FEATURES OF OTHER FORMS OF TREMOR. By Dr. R. T. Williamson. Brochure, 70 pages. Illustrated. Sherratt & Hughes, Manchester.

A SYSTEM OF PHYSIOLOGIC THERAPEUTICS. Edited by Dr. S. Solis Cohen. Vols. III.-IV. CLIMATOLOGY. By Dr. F. Parkes Weber, with the collaboration in America of Dr. Guy Hinsdale. 2 vols. 8vo, 336, 440 pages. Illustrated. P. Blakiston's Son & Co., Philadelphia.

THE STANDARD MEDICAL ANNUAL. By Dr. A. S. Burdick. 8vo, 921 pages. Illustrated. G. P. Engelhard & Co., Chicago.

A REFERENCE HAND-BOOK OF THE MEDICAL SCIENCES. New Edition. Edited by Dr. Albert H. Buck. Vol. III., Chl.-Equ. Quarto, 860 pages. Illustrated. William Wood & Company, New York.

AMERICAN EDITION OF NOTHNAGEL'S ENCYCLOPEDIA. TYPHOID AND TYPHUS FEVERS. By Dr. H. Curschmann. Edited by Dr. William Osler. 8vo, 646 pages. Illustrated. W. B. Saunders & Co., Philadelphia and London.

ATLAS AND PRINCIPLES OF BACTERIOLOGY AND TEXT-BOOK OF SPECIAL BACTERIOLOGIC DIAGNOSIS. By Drs. K. B. Lehmann and R. O. Neumann. Second Edition. Edited by Dr. G. H. Weaver. In Two Volumes. W. B. Saunders & Company, Philadelphia and London.

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LXXIX. NEW YORK, SATURDAY, DECEMBER 28, 1901. NO. 26.

SPECIAL ARTICLE.

SOME SURGICAL TENDENCIES FROM A MEDICAL POINT OF VIEW.[1]

BY REGINALD H. FITZ, M.D.,
OF BOSTON.

IT WAS not without considerable hesitation that the honor of addressing you this evening was accepted, especially as what I am about to say is somewhat opposed to the prevailing tendencies of the day and relates rather to differences of opinion than to well-established principles. If I pay too much attention to the other side of the subjects brought before you it is because this is less urgently advocated at present than the reverse. The importance of the subjects, however, is unquestionable since they belong to the borderland of medicine and surgery and may be stated as some surgical tendencies from a medical point of view.

The region mentioned obviously includes both the province of the physician and the domain of the surgeon. These terms may be supposed to represent the modest claims of the former and the imperialistic tendencies of the latter. It is common ground, however, and the successful advance of either surgeon or physician into the region previously occupied by his colleague will always be welcomed provided the interests of mankind thereby are served.

The improvement in methods of surgical procedure during the last thirty years has so greatly increased the number and variety of surgical operations that it has seemed to me desirable to question the value of some of these and especially to pay more attention to the subsequent history of the patient than to the immediate success of the operation. As physicians we have been duly impressed with the progressive diminution in the mortality-rate of operations, but we are far more concerned with the degree of benefit which the patient may have experienced. For centuries the pathologist has taught that there are diseases so mortal in their progress as to be regarded as practically incurable. The advance of knowledge shows that the number of these apparently incurable diseases is somewhat diminished by a more intelligent classification of symptoms and lesions, and that all diseases which have received a common designation are not necessarily identical. There still remains, however, a considerable group of what the physician regards as hopeless cases, and of late years especially he has been in the habit of asking his surgical colleagues to make some attempt to relieve the condition of these patients. Numerous efforts have been made and most encouraging results have been published, especially elsewhere. Unfortunately, when the comparison is drawn between such results and those under familiar conditions the conclusion is not so satisfactory as is to be desired.

It will readily be admitted that a sufficient trial of surgical treatment is justified in many cases where mechanical disturbances exist which medicinal treatment cannot relieve, provided the life of the patient is not endangered by the operation. Experience has shown that certain cases previously regarded as extremely dangerous or fatal without surgical treatment have been greatly benefited if not cured by such treatment. On the other hand, experience also has shown that immediate death, extremely short relief or prolonged suffering have resulted from operations designed to give longer life or greater freedom from distress than the physician could hope to offer. The surgeon is willing to operate upon the presumably hopeless case because the patient often survives the operation and may be benefited. The benefit is to be hoped for since at times the diagnosis proves faulty and remediable conditions are found. If the diagnosis proves correct and incurable lesions are met, the patient is regarded as no worse off than before the operation, while the latter may relieve suffering and prolong life. The physician, therefore, is encouraged to transfer his patient and give him what is often called the benefit of the doubt. Unfortunately, a not infrequent result of the operation under such circumstances is the death of the patient somewhat earlier and with more suffering to mind and body than if spared the surgeon's aid. In such cases the value of the doubt must be considered as problematical.

The failure of the surgeon to relieve to any great extent the sufferer from a supposedly incurable disease leads him to request the transfer of the patient at a time when the characteristic features of the affection are less pronounced, with the hope that the morbid process may be arrested at an early stage. Indeed, he may wish to attempt relief at a time when in the light of our present knowledge it is impossible to make a diagnosis. The physician may suspect the grave, perhaps fatal nature of the malady, but, owing to the similarity, if not identity, of the symptoms to those of less serious conditions, he feels compelled to wait for further developments.

The surgeon, on the contrary, would at once make an exploratory incision on the ground that the better the patient's general condition the less the immediate danger from the operation to the patient's life, and if the supposed lesions are encountered the chance of relief is increased. But the diseased appendix is found normal, the acute

[1] Anniversary discourse before the New York Academy of Medicine, Dec. 5, 1901.

intestinal obstruction proves to be a phantom tumor, the incarcerated gall-stone is non-existent, the abdominal tumor becomes a harmless enlargement of the liver. Exploratory laparotomies are undertaken for the relief of suspected cancer of the stomach and no cancer is disclosed. There are patients, too, often more desirous of the operation than is the surgeon who is to perform it. The experience presumably is not unique in which a patient undergoes removal of the ovaries, uterus and vermiform appendix for asserted pelvic and abdominal pains, and subsequently presents herself for surgical exploration of the region of the pancreas. The pain referred to this organ proves, without operation, to be dependent upon disordered gastric function of neurotic origin. Dr. Foote at a recent meeting of the Harvard Medical Society of New York reported the case of a young man who complained of abdominal pains. The physical examination showed the scars of four laparotomies, one of which had been performed in Russia and three in this country. On the same occasion Dr. Gibson mentioned that a normal appendix, seven inches long, had been removed from a patient who claimed to have had previously seven attacks of recurrent appendicitis. The patient, not content with this demonstration of a normal appendix, subsequently applied at the Roosevelt and Bellevue Hospitals for treatment for appendicitis. It is not to be wondered at that the host of neurotic and neuropathic men and women seek for operative relief for real and fancied ailments when they receive such advice as the following, taken from the editorial column of a daily paper: "It is probably true that the Dowager Empress Frederick's life could have been saved if she had been willing to have her stomach amputated. There are enough stomachless human beings alive and flourishing, and slight enough record of failures of the operation, to have made the chances distinctly even. The discomforts are not many, either; a few rules must be followed. The food must be cut up very fine and carefully masticated. One must show moderation at meals. The man without a stomach cannot eat as much as the man who has one. Everything must be warm, because the stomach, which heats food for the intestines, is missing."

Exploratory laparotomies whether by advice of the physician, desire of the surgeon or urgency of the patient are only too frequent. They are not without considerable danger and often disclose conditions which cannot be relieved and which might have been appreciated without an operation. The high mortality in such instances often is attributed by the surgeon to the disease and not to the operation. Not infrequently they are undertaken without sufficient forethought. They tend to make the physician superficial in observation, since the diagnosis is to be made definitely by means of the operation. They lead the surgeon to become only too ready to act upon the diagnoses of those often incompetent to make them, either through ignorance or inexperience, since the actual condition is likely to be made clear by his skill. Each case should carefully be scrutinized both by physician and surgeon before this operation is undertaken. The former may find conditions which will nullify the success of any operation; the latter may be led to recognize that the exploration can but add to the discomfort of the patient without prospect of any definite relief. It should not be made for diagnosis simply, but always for the purpose of curing disease or of relieving suffering. The art of the surgeon should ever be regarded as sanatory and should be called upon as rarely as possible to make a diagnostic procedure of what is essentially a therapeutic measure. The exploratory operation which discloses nothing is more likely to reflect upon the judgment of the surgeon who performs it than to represent a tribute to his skill.

In partial justification of these statements, as well as of others which are to follow, I have asked a former assistant, Dr. G. A. Waterman, to examine the records of the Massachusetts General Hospital during the period of ten years from 1890 to 1900. This decade was selected as it is recent enough to include many of the advances which have been made in operative technics and the years represented are sufficiently numerous to furnish an experience of profit. The value of the evidence lies in part from its source and in part from its representing the experience in a single institution of a number of surgeons identified with the practice of surgery in general.

FREQUENCY AND RESULT OF EXPLORATORY LAPAROTOMIES AT THE MASSACHUSETTS GENERAL HOSTITAL FROM 1890 TO 1900.

	1890	1891	1892	1893	1894	1895	1896	1897	1898	1899
Number of operations	10	5	15	13	15	21	39	23	42	30
Cases of malignant disease	8	2	9	8	5	8	25	7	28	18
Number of deaths	3	2	7	8	7	9	11	13	16	11
Failure to relieve	6	2	5	3	2	5	22	3	17	13
Relief or securing diagnosis	1	1	..	1	2	5	5	4	6	5
Cure	..	..	3	1	4	2	1	3	3	1
Percentage of malignant disease	80	40	60	61	33	38	64	30	66	60
Percentage of deaths	30	40	46	61	46	42	28	56	38	36
Percentage of failure to relieve or cure	90	80	80	84	60	66	84	69	78	80

The following table shows the increasing frequency and various results of exploratory laparotomies at this hospital. It is not asserted that all such operations occurring during the years included are tabulated, only as many as could readily be ascertained by an examination of the records, hence the figures are to be regarded as chiefly of relative value. Many successful explorations undoubtedly are recorded under titles other than that of exploratory laparotomy. The total mortality and the failures to cure may be distinctly less than stated, but they indicate sufficiently that an exploratory laparotomy, except in especially selected cases, is an operation which carries a very decided immediate risk to the life

of the patient and a very considerable doubt as to the degree of relief to the symptoms. In general, with the increasing frequency of these operations there is some lessening of their mortality-rate, although the percentage of relief and cures is not especially improved.

The relief of suffering and the lengthening of life are legitimate aims for the surgeon as well as for the physician. The methods of the former are necessarily so much harsher than those of the latter that it may well be questioned whether too many operations are not performed with these objects in view. Granting that life may the more be prolonged by the aid of the surgeon, is the life thus extended worth the living? Neither physician nor surgeon can answer this question with any degree of certainty until the life of the patient has been lived. But the physician and surgeon are called upon to advise and are not always united in their opinions. It is often the tendency of the surgeon so to express himself to the sufferer that the latter frequently is made more hopeful than is justified by the evidence at hand. He is likely to bring before him the most favorable outcome of the suggested operation. The mortality is apt to be placed as low as has been obtained by the most skilful and experienced of the world's surgeons, although it may be far the reverse in the practice of the surgeon concerned. The degree of relief obtainable is likely to be exemplified by the exceptional instances, not by the rule, for the surgeon is more likely to recall the few successful cases seen at more or less frequent intervals than the numerous fatal cases of whose history after recovery from the operation he may know nothing. Assuming that the diagnosis of the conditions suggesting surgical treatment is clear, it is often found that complications exist rendering any treatment useless. The resection of ribs and drainage of the pleural cavity in pyopneumothorax seem of but little value when there is extensive tuberculous infiltration of the lung on the side opposite the diseased pleura. The operation must be regarded as worse than useless if at the same time there is evidence of amyloid disease of the abdominal viscera. What avails the extirpation of a renal tumor if at the time of the operation secondary nodules are present in the brain or lungs? The more learned in pathological anatomy the adviser is the more cautious will his prognosis be. Unfortunately, it is the tendency of the day for the surgeon in general to neglect this branch of knowledge. He is inclined to devote himself rather to the bacteriopathology which makes his operation succeed than to the postmortem examination which usually gives ample evidence of the cause of the patient's death.

It may be unwise for the sick man to be placed in any other than a hopeful position before the operation, but the latter should not be decided upon until those nearest the patient are as thoroughly informed upon all points as possible. It is especially for the physician on such occasions to realize his responsibilities and to prepare himself to meet them, since it is he who eventually is the less likely to be relieved of them. He cannot discharge this obligation by transferring his trust to the care of the surgeon, but should endeavor to aid the latter to the utmost possible extent. The patient then will be in a better position to decide whether he will prefer the known to the unknown, for, with the best intentions of the surgeon, the future of his patient is only to be forecast by past experience, and, fateful as this may be, it not infrequently is rather to be welcomed than the alternative offered.

Such statements receive their strongest illustration in malignant disease of the alimentary canal. Both surgeon and physician are agreed upon the usually fatal outcome of this affection and the uncertainty as to its duration. They are fully aware that in many cases death is likely to be preceded by great suffering from mechanical obstruction. Nevertheless the surgeon is ready to operate because there is a possibility of error in the diagnosis and the symptoms may prove to be due to a remediable cause, or the obstacle may be removed or overcome for the time being. The abdomen therefore is explored, first to make clear the diagnosis. Should this prove correct, even if there is evidence of extensive incurable disease, the inclination then is strong to attempt some sort of relief by resection, gastrostomy, anastomosis or colostomy. The surgeon may urge resection on the ground that it has successfully been performed by himself or by others and if the patient survives the operation pain is likely to be relieved and a life of usefulness may be prolonged for a number of years. He may present as an alternative anastomosis with its somewhat lower mortality and less favorable outlook as to the duration of life. With the discovery of conditions unfavorable to the former operation and mindful of the high mortality-rate of anastomosis, recourse may be had to colostomy with its customary disagreeable and annoying after-effects, producing at the best only a kind of relief for an uncertain period of time. The physician knows that without any operation apparently insuperable obstructions have yielded and indefinite periods of active life have subsequently been enjoyed. He knows that if the symptoms of obstruction persist the patient's suffering may be lessened by medicinal treatment, and that such treatment often is necessary even after temporary comfort only is obtained from an operation. He may know also that the surgeon himself, when asked what he would desire if in the place of the patient, has replied that he should prefer to die during the operation or to live the least possible time after it, than to prolong life at the probable cost of health and happiness. The higher its mortality the warmer would be his welcome of the operation.

In order to obtain the experience of patients after such operations upon the alimentary canal,

an inquiry has been addressed to the friends of a considerable number of those who have been operated upon at the Massachusetts General Hospital during the period between 1890 and 1900 for diagnosticated and demonstrated cancer of the stomach and intestines. Information was sought as to the degree and duration of any relief which may have resulted from the operation. The replies which have been received, including the information derived from the hospital records, pertain to nearly three-fourths of the cases thus investigated and show clearly what has been the melancholy outcome in many of the cases of this class of gastro-intestinal disease so generally cared for at the present time by surgeons. The pathos of some of these replies makes them all the more convincing.

It should be stated that it is probable that all the patients operated upon during this period are not included, that successes may have been overlooked, and that few or many of those from whom no replies were received are likely to have undergone the more favorable experience, if such it may be called, of prolongation of life, perhaps even of relief from suffering. Regarding the mortality and duration of life as relative, and the percentage of suffering as inexact, the evidence presented nevertheless must be considered as offering grave doubts as to any considerable benefit from this class of operations as a whole. It may be that the coming ten years will prove more encouraging, but the enthusiasm of the operator should not permit a warping of the judgment based upon so recent an experience.

In the series collected there were fourteen operations for cancer of the stomach. These included four gastrostomies, all the patients, with the exception of one not heard from, dying within two months, and four pylorectomies, one of which was not heard from, two died within the first month after the operation, and the fourth was relieved for several months; at the end of six or eight months, however, the last patient began to fail and died at the end of a year and a half.

Of the six gastro-enterostomies, four died within seventeen days, one "received no relief whatsoever and after twelve weeks' of terrible suffering passed away." The sixth felt quite well for about two months after the operation. He was then confined to the bed the greater part of the time and "suffered untold agony" till his death nine months later.

There were ten cases of intestinal resection, of which eight died within a month after the operation. The ninth patient was found to have a girdling ulcer without gross evidence of malignant disease, although from microscopical examination regarded as an adenocarcinoma. He was at work as janitor and enjoying fair health two and a half years after he was operated upon. The tenth patient was not heard from. Of the five cases of intestinal anastomosis two died within the fortnight following the operation, one lived six months and two have not been heard from.

There were 49 inguinal colostomies and the subsequent history of 37 of these has been ascertained. Twenty-eight of the latter died within the half year following the operation. Two lived between six and twelve months; five lived from one to two years and two lived twenty-seven and thirty months respectively after the operation had taken place. Thus only a few more than one-fifth of the cases heard from were alive one year after the operation.

When the question of relief of suffering is considered it appears that among sixteen patients who fully recovered from the immediate effects of the operation and lived four months or more after it, there was some or much relief in eight and no relief also in eight. The operation was regarded as "decidedly unsuccessful" in a patient who died a month later and in ten days after leaving the hospital. A patient who lived for two months was afforded "only temporary relief." Another living three months received "very little relief." One who lived four months was relieved "of the intense agony she was almost constantly suffering previously. After the operation the pain occurred occasionally." Her last four months of life, however, were spent in the hospital. Of a patient who lived five months it is stated "the operation was no relief. The pain from the running sore continued. Only for the pellets you prescribed in the hospital he would be screaming all the time. They had the effect of deadening it." Another who lived five months "derived no benefit from the operation . . . She suffered intensely except when under the influence of opiates. . . . No doubt the operation prolonged the suffering." A patient who lived six months after the operation had "slight temporary relief from acute suffering, but she never regained strength." Another patient also lived six months "free from pain that was severe until the end, and the chills were less. An ugly growth formed on the outside which caused him much uneasiness." The patient who lived sixteen months died "after a painful illness which lasted till death. Excepting a few days at a time he was continually in pain and under doctor's care." For one who lived twenty-one months "the relief did not last only about three months. Then he was a great sufferer the rest of the time." The life of one patient was prolonged "for two years, during which time he suffered continually. The relief afforded lasted about three weeks, and from that time on his suffering steadily increased." Of another patient who lived also two years it was learned that "he never was so he could sit up, but he thought it must have been a great relief to him to have the discharge come the way it did. He thought that he lived longer by having the operation, although he would have been glad to go long before he did, he suffered so much. He suffered a great deal but he had a medicine . . . that took away the pain in a measure. . . He said if it was to do

again he should have the operation as before." The two patients who lived twenty-seven and thirty months respectively were relieved for a year. Each was then operated upon for a second time, after which the condition was one of invalidism.

There were eight cases of anal excision of rectal cancer, three of whom were not heard from. Of the others, one died within a week, two lived fourteen and eighteen months respectively, the fourth was living and well at the end of two years, but in this case the nature of the growth does not form a part of the record of the case. The fifth patient is now alive and well, nearly twelve years after the operation. The microscopical examination of the specimen showed "a fibrous tissue stroma the spaces of which were filled with epithelial cells." Nevertheless the result in this case is so exceptional that a legitimate doubt must be raised as to the cancerous nature of the tumor. The evidence recorded is not sufficient to remove this doubt except from the mind of the sanguine surgeon. The patient who lived fourteen months became "an intense sufferer. He had to take morphine for relief. When he died he was a mere skeleton. When he got home he had not control of himself and used one pound of cotton a week; at the time of his death he used seven pounds." Concerning the patient who lived eighteen months it was stated that she "was relieved for only two months and then it began to trouble her and she lived until March 19th, 1892, and some of the time suffered intensely. The last six months was under the influence of opiates most of the time."

Of the seventeen Kraske operations seven were not heard from. Of the ten remaining, seven died within the year following the operation. Three lived twenty-two, twenty-nine and thirty-two months respectively. One patient remained in the hospital for two months after the operation, then returned to her home, "lived four weeks and was a great sufferer during that time." A patient who lived eight months after the operation "was a constant sufferer from the time he was operated on until the time of his death." Another one who lived twenty-two months "never worked at all, as he was not able. He did not suffer very much until he was home about a year and after that he suffered something terrible, could not get any relief at all; he was just as helpless as any infant." Of the patient who lived twenty-nine months it was stated "that *no* relief followed operation. It was no doubt a success, but the cancer grew within a year and although the operation prolonged my father's life, complications arose resulting from the *new* rectum, and it was worse, much worse than cancer. My mother died six months after my father. She passed through a serious operation, died also of carcinoma. If ever I have the dreadful disease I shall insist to be filled with morphine and die sooner, although I believe in operations, but not for that disease." The patient who lived thirty-two months "enjoyed fairly good health for six months, but after that she never saw a well day."

Of the cases of cancer of the alimentary canal whose history subsequent to the operation for the relief of this affection was learned, it appears that 28, or 36 per cent., died within one week; 15, or 19 per cent., died between one and four weeks; 14, or 18 per cent., died between one and six months; 4, or 5 per cent., died between six and twelve months; 9, or 11 per cent., died between one and two years; 4, or 5 per cent., died between two and three years; 3, or 3 per cent., lived as above stated. Thus 54 per cent. of these cases died within a month after the operation and 72 per cent. within six months. Any considerable prolongation of life applied, therefore, to less than 30 per cent. and to many of these the life was one of suffering and sorrow necessitating the frequent or constant use of opiates to obtain any measure of relief.

Intracranial tumors form another series of growths which have been operated upon for a sufficient number of years to permit a medical opinion to be formed of the value of this operation. Of the 15 cases included in the decade under consideration the subsequent history is known in ten. Of these four died on the day of the operation. One died at the end of three days, a fourth at the end of eleven days, another at the end of three weeks and one at the end of a month. Thus, within the month following the operation eight out of ten cases died. The ninth patient died in the hospital at the end of ten weeks. Of the tenth patient it is stated "that previous to the operation he suffered most intensely from headache and vomiting with attending weakness. After the operation (the immediate effects having passed away) he was comparatively free from pain and there was some gain in his speech and paralysis. The second operation was more successful and he was much better, being able to drive and go about in the cars, etc. The improvement lasted until two or three weeks before his death when he began to show signs of failing." He died seven months after the second operation, which followed the first by a month.

The treatment of tumors of the kidneys also occupies the debatable ground between medicine and surgery, and the experience at the hospital during the decade mentioned again offers but slight encouragement to the surgical treatment of this affection. There were eleven nephrectomies for malignant disease of the kidney and replies were obtained relative to the fate of eight of these patients. Four died within a fortnight of the operation, another at the end of two months, a sixth at the end of three months and another at the end of five months. The eighth patient was living and practically well three years after his operation. The examination of the tumor after removal showed that the growth, stated to be a sarcoma, proceeded from the suprarenal capsule, the kidney being but little altered.

Physicians will readily admit that the surgical treatment of external malignant tumors frequently offers a source of relief to pain, deformity and incapacity with but little immediate risk to the life of the patient. With the recognition that the disease probably will recur, the hope is maintained that recurrence may long be delayed, that it may take place within internal organs and prove relatively painless, or that death may result from some intercurrent affection wholly independent of the original disease. External tumors thus seem to fall wholly within the region of surgery. The physician, however, should stand ready to reclaim from the knife what may otherwise be satisfactorily treated. The surgeon is quite willing to transfer for medical treatment after operation the case of disease which may recur, with the hope of avoiding or postponing recurrence, but in certain instances it is apparent that medicinal or non-operative measures are to be tried before an operation is undertaken. No more satisfactory instances of the value of such treatment have been reported than those of W. B. Coley from the use of mixed toxins and those of F. H. Williams and others from the use of the Röntgen rays. Certain tumors of the neck in particular may be said to lie in this borderland of medicine and surgery. Long regarded as demanding surgical treatment in the first instance, the repeated unsatisfactory result of such treatment inevitably leads to the conclusion that surgical methods are to be employed only as a last resort after other measures have failed. The patient seeks medical advice for enlargement of the thyroid gland. The physician, perhaps not well informed, sends the patient to the surgeon who frequently takes the shortest way of riding the patient of the deformity, unmindful that thyroids are not to be removed simply because they are enlarged. Indeed, the deleterious effects of this treatment are only too well known by those who have seen the patient subsequently suffer from cachexia strumipriva, to obviate the effects of which various modifications in operative treatment have been introduced and medicinal treatment has become necessary. It is always to be remembered, however, that we are mainly indebted to a surgeon, Kocher, for our knowledge of the curative effects of iodine in 90 per cent. of the cases, to say nothing of his more recent recommendation of phosphorus, thus rendering operative surgery unnecessary if not injurious in this proportion of the patients.

The wise surgeon realizes that the operative treatment of goiter is demanded only for such varieties as have undergone secondary changes. The colloid and cystic, the fibrous and calcified portions alone are those primarily demanding the use of the knife, provided the deformity is sufficient, while the parenchymatous enlargements usually rapidly subside when submitted to the treatment with iodine. If a part of the thyroid gland presents the characteristics of these secondary degenerations, it does not follow that the entire gland is disorganized. It is for the surgeon so to familiarize himself with the pathology of this structure as to treat what demands surgical measures, but to refrain from his treatment of such goiters, entire or in part, as can more successfully otherwise be cared for.

Even if the limitations of the medical and surgical treatment of goiter are well understood, it would seem that the relation of enlargement of the thyroid to Graves' disease is frequently misunderstood. The surgical treatment of the latter affection finds new advocates from time to time and the value of this treatment is supported by columns of most encouraging figures. It must be remembered, however, that the term goiter means merely enlargement of the thyroid gland and that such enlargement differs in etiology, structure and in associated disturbances of function. Admitting that the removal of a considerable part of the diseased thyroid from a case of sporadic goiter produces a cure by relief of the deformity and of the immediate mechanical and remote constitutional disturbances, it by no means follows that this operation is to afford a like relief in Graves' disease. In the former affection the goiter is a cause of the disturbances, in the latter it is one of the disturbances the cause of which is unknown. Removal of this deformity, so often a vascular goiter, merely takes away one feature of the disease and has repeatedly led to the sudden and unexpected death of the patient, either on the operating-table or while apparently in a state of normal convalescence from the operation. It would seem as if the reported successes of the surgical treatment of Graves' disease were attributable rather to a lack of agreement as to what should thus be designated than to the especial skill or good fortune of the operator. Buschan's conclusions from his analysis of such reports are so suggestive that in genuine Graves' disease extreme or threatening deformity alone is to be regarded as a satisfactory indication for the removal or obliteration of considerable portions of the diseased thyroid.

In like manner the surgical treatment of malignant lymphoma is to be disputed. Here again we have to deal with progressive disease tending to produce extreme deformity of the neck often before other parts of the body are invaded. It is only after many years, even centuries of observation and experience, that the glandular deformities of the neck have become more and more sharply defined, grouped and classified. Even now there is apparent uncertainty and lack of agreement as to the significance of the term malignant lymphoma and the relation of this alteration of the lymph-glands to other changes in the structure of these glands. That certain of the regional enlargements of lymph-glands, with or without any considerable increase in the leucocytes of the blood, pursue the course of a malignant disease and eventually prove fatal is universally known. The resulting deformity is so annoying that the patient hopes to find speedy relief in the extirpation of the tumors. The uselessness of this treatment of leucemic lympho-

mata seems almost universally recognized. In a leucemic malignant lymphoma, however, despite failure after failure on the part of the surgeon to afford anything but the briefest possible relief to deformity, case after case continues to be operated upon before any sufficient trial of medicinal treatment has been made. Finally, the discouraged patient returns to his physician with equal, if not greater, deformity than before from the enlarged glands. Despite the limited value of the arsenical treatment of this disease, it is likely to be advised after the operation and if of value then, as it sometimes is, although perhaps temporarily, it is likely to have been equally useful before operative treatment was undertaken. Despite such experiences, operations are so frequent upon this class of patients that it would seem as if ignorance of the progress of this disease prevailed, that its nature was unrecognized or that the patient had not been fully informed of the inevitable outcome.

The ilustrations here presented are but a few drawn from the borderland of medicine and surgery and it is unnecessary and perhaps undesirable to extend them indefinitely. They are not intended to oppose the surgeon in his persistent efforts to relieve suffering humanity, but to emphasize the importance of the careful study and selection of suitable cases. It is not to be expected that the practice of the healing art is to be based solely on hygiene and surgery, the former to prevent, the latter to relieve or cure disease, although this assertion so frequently has been the shibboleth of the last quarter of a century. The value of remedies in common use is sufficiently well established to permit their limitation to be recognized and progress in the future is likely to depend much more upon the discoveries which shall make surgery less necessary than to open new fields for surgical treatment. Fully recognizing the marvelous benefits to humanity which anesthesia and asepsis have brought about, it must be admitted also that these benefits are not wholly unalloyed. Operations are undertaken which are followed by the immediate death of the patient, others prove to be wholly unnecessary and still others leave the patient in a condition of helpless invalidism, often making life worse than death. Any operation which does not better the condition of the patient must be regarded as a therapeutic error, since the knowledge thus obtained shows that the operation should not have been performed.

The advance of knowledge in the future should be in the direction of limiting these unnecessary and harmful operations, for the wisdom of the surgeon should serve as well to restrain him from operating as to enable him to operate successfully. Especially to be cultivated for these purposes are greater accuracy in diagnosis and prognosis, and the more widespread knowledge of pathology and pathological anatomy. The surgeon thus will become a better adviser although the number and variety of his operations thereby may materially be lessened.

TREATMENT OF LOBAR PNEUMONIA.[1]

BY CHARLES G. STOCKTON, M.D.,

OF BUFFALO;

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND CLINICAL MEDICINE, UNIVERSITY OF BUFFALO; ATTENDING PHYSICIAN, BUFFALO GENERAL HOSPITAL.

I HAVE listened to many and have taken part in not a few discussions on the treatment of lobar pneumonia, and, as a rule, have come away from such interchanges of views impressed with the fruitlessness of the effort. The universally-accepted doctrine that the disease is self-limited leaves still a shadow of doubt upon the brilliant results of those who are enthusiastic over any one of the many special forms of treatment. Men of large experience find that the mortality of pneumonia under the same management varies from time to time and that while the type of the disease may vary from season to season, its manifestations as seen in one patient are strikingly unlike those seen in another under apparently the same conditions.

I find cases of lobar pneumonia that are abortive, the crisis being reached after two or three days; other cases in which the involvement of the lung is very late in appearing and the resolution equally late; still other cases, the so-called serpiginous type, in which the process gradually extends from one portion of the lung to another, very well described by the old term "spreading." Still another type is that in which the disease wanders from lobe to lobe, the illness sometimes lasting three or more weeks. Again, there is a form that follows the rule except that though resolution does not occur as expected, yet the lung does not break down. Several weeks may elapse before the unwilling disappearance of the consolidation. This is not to be confounded with chronic lobar pneumonia which takes on the interstitial form, much of the lung being converted into fibrous tissue. Finally, we have the latent pneumonia of the aged; and, occasionally, a form that closely resembles this latter, which appears in the feeble and depressed from other causes than age.

When we come to consider the nature of lobar pneumonia, the foregoing statements are not surprising. We have to combat an infectious disease which usually finds its port of entry through the respiratory tract, and which probably finds in the lungs a focus for the growth and distribution of the specific micro-organisms. Just to that extent it is probably in the beginning a local process. and yet several days of profound illness may supervene before the appearance of those phenomena which we recognize as inflammatory. It is true that, as a rule, within the first twenty-four hours we discover the evidences of extensive inflammatory exudate; but, on the other hand, this may be delayed several days or even a week. Meantime, the patient is profoundly ill, having had an initial rigor, high temperature,

[1] Read before the Lake Keuka Medical Association, Aug. 14, 1901.

and prostration. We have come to understand that this means not so much the general infection of the body as a general intoxication, following the absorption of the toxins developed in the growth of the specific organisms. What we observe in our patients is the reaction of the tissues of the body against the toxin that is distributed generally through the circulation. As in diphtheria, so in pneumonia, whatever else we have to contend with, there stands first and foremost the toxemia. So true is this that some therapeutists feel that successful treatment of the affection must be directed solely against the toxemia. Certainly the matter of intoxication demands our constant and most serious attention. Indeed, in many cases it is the paramount question, and in a few cases it is practically the only question that needs our attention. Unfortunately, however, the toxin cannot be disposed of in any general way. Not every part of the patient's economy resists the toxemia with equal success; there is always a point of least resistance. Most commonly, we find this to be the heart, and ultimately this comes to be almost invariably the case; but before the heart has failed and, not rarely, as one of the active factors in producing cardiac depression, is the disability of other organs, or apparatus. Thus, the blood-making organs may fail to react and there is the absence of the natural leucocytosis. The liver and kidneys may be so crippled that a secondary toxemia develops which proves to be as unmanageable as that of pneumonia; and, finally, the nervous system may be so injured that rest is impossible and the functional activity in general, or in particular, is greatly handicapped.

These varied expressions of the intoxication of pneumonia explain the divergence from the typical in the course of the disease. It is, therefore, evident that lobar pneumonia must require different management in different cases and, in a greater degree than most diseases, it offers a field for clear-sightedness, intelligence and readiness on the part of the physician. We must find some comfort in knowing that there are a few methods which we may employ almost universally to assist Nature in her fight against the toxemia. There can be little doubt about the almost universal need of the preliminary calomel purge. Enough should be given to empty promptly the alimentary tract and to increase the activity of the liver and kidneys. The internal congestion can be still further relieved by the occasional use of magnesium or sodium sulphate, both for diuretic and purgative effects. There is a general agreement as to the importance of the treatment of the skin, although we differ in our methods. In the Buffalo General Hospital we almost invariably employ the hot mustard foot-bath followed by sponging. We have a particular way of giving the bath, and repeat it every two to six hours, according to the indications. The object is not only to promote diaphoresis, but to stimulate the cutaneous circulation, and thereby increase the efficiency of the heart. When the bath is given with sufficient care it fatigues the patient but little and is usually followed by considerable, and sometimes very marked, relief of symptoms. All are agreed that the general circulation demands attention. High blood-pressure and an exaggerated heart action are likely to do harm; they foreshadow a great pulmonary congestion and consolidation and irritate the brain. The realization of this formerly led to the use of antimony, veratrum viride, and other depressants, now mostly out of vogue. We usually find ourselves able to manage excessive circulatory activity by the purge and the foot-bath. The depressant drug is rarely needed; though I would not say that it is absolutely and invariably to be excluded. It is sometimes wise to employ cold compresses or ice bladders over the chest and, where the temperature is excessive, I have seen great benefit follow the cold bath after the manner of the Brand treatment in typhoid fever.

What one fears more than excessive circulation is depression of the heart or lowering of the blood-pressure and adynamia, the approach of which always causes uneasiness. In my experience the best way to manage this tendency is, so far as possible, to prevent its appearance. This doctrine is not new and it is the basis of various forms of treatment that, from time to time, have been highly lauded as being applicable to most cases. For instance, there was the treatment by alcohol or quinine in full and oft-repeated doses, the giving of ammonium salts *ad nauseam,* the administration of digitalis in heroic doses; all of which methods still have their advocates, and yet to-day these are for the most part abandoned. Of course, each of these measures has its place, and there is an occasional hour and an occasional case when one of these remedies meets the indications peculiarly well; but, according to my experience, the only drug upon which we can place any reliance is strychnine, given hypodermically and in full doses. In many private and in most hospital cases I find that it is necessary to begin the use of strychnine early, and in my hands the only limit to the dose is the sought-for physiological effect of the drug. Beginning with $^1/_{30}$ of a grain, this is repeated every two or four hours, and increased to $^1/_{20}$, $^1/_{15}$, or even $^1/_{10}$ of a grain, if the condition of the circulation demand it. At a certain point in pneumonia to allow the heart to fail is to invite, nay, to secure rapid pulmonary congestion and edema, with an early fatal termination of the case. To avoid this result we must use strychnine freely. I have often found it necessary to give minute doses of opium to counteract the irritation that the strychnine causes to the nervous system. The unpleasant effects of strychnine can thus be overcome without in any way endangering the patient from the effect of opium through depression of the respiratory center. In these larger doses strychnine is also of use in assisting elimination; the purgatives and diuret-

ics thus become more effectual. As to the nervous system, it should be guarded by allowing the patient every possible opportunity of rest. The baths, the nourishment, the medication should as much as possible be administered at about the same time, so that there may be the longest practicable interval for composure. Sleep may be favored by the ice-bag to the head and by chloralamid or Dover's powder. As a rule, the patient should not be wakened for any purpose; but if he sleeps beyond the expected hour, the nurse should be ready the moment he awakes to prevent depression, restlessness and discouragement, by the prompt administration of nourishment, strychnine, and if necessary other stimulants. This is a practical point which seems to me of considerable importance. As to the efficacy of antitoxic serum in counteracting the toxemia, although I have had some experience with it, I am not prepared to give an answer. I am inclined to think that it possesses some value in that direction, but feel that there is danger in expressing an opinion upon insufficient data.

We have now to consider another side of the treatment of lobar pneumonia, and that has to do not so much with the effects of the toxemia upon the other parts of the organism as the effects of the direct infection upon the tissues of the lungs. In other words, we are not yet in a position to look upon pneumonia solely as a systemic disease, but must remember that it is also a local process; and, in some cases, the local process outweighs in importance that which is systemic. I am convinced that the safest method of treatment is one which takes cognizance of this quality of processes in pneumonia, and which directs its therapeutic measures not only toward protecting the patient from poisoning, but also in saving him from the danger that comes, sometimes very suddenly, in hepatization and in the congestion and edema of the lungs.

It is a source of satisfaction to me when I find the hepatization of one lobe appearing early in the course of the disease. Those cases in which the consolidation is delayed are apt to be more toxic, and when the organ finally becomes hepatized it is likely to be associated with more collateral congestion and edema than in the former class of cases. I do not wish to imply that early in these delayed cases the lung has escaped the effect of the disease; on the contrary, it is probable that in the beginning of the attack the lung is in a certain sense crippled, even though the physical signs of serious involvement are absent. If in one of these toxic cases, in which the consolidation is delayed, one will carefully auscultate the chest, he will find that there is evidence of disturbance of the air cells in the very beginning of the attack. The character of the vesicular murmur is changed to some extent. It loses the soft, breezy character of pure vesicular breathing, the quality is somewhat harsher, while at the same time the vesicular element is feebler. It is highly probable, as suggested by Dr. Eugene Wasdin, that the immediate result of the pulmonary infection, associated with the local effect of the toxin, is to diminish the natural tissue-tone, leading to a condition in some of the alveoli that approaches atelectasis. This is a condition which is almost universally seen early in the lung of influenza. I do not mean to infer that it appears to the same extent in the very beginning of lobar pneumonia, but I am satisfied that the same process does exist to a certain extent; and this preliminary change may antedate by several days the classical congestion and succeeding hepatization which we so well understand.

M. Variot, before the French Société de Pediatrie (*Bulletin Médical*, Nov. 17, 1900) stated that those patients who present the general symptoms of pneumonia, but in whom there is absence of physical signs, may nevertheless be found by means of the radiograph to have a local process already established as shown by the faint shadow which deepens as the lungs become consolidated.

By careful and repeated examinations, we may be able to predict very early in the disease which lobe is likely to follow the first onset of consolidation, even when that process is considerably delayed. I am not aware that we have as yet means at our command for combating this first impression made upon the lung tissue; but I am convinced that there are measures which, if intelligently applied, will often succeed in postponing the hepatization from twelve to twenty-four hours, which postponement occasionally means everything in the ultimate outcome of the case. It is not to be supposed that the claim is made that consolidation of the lung in lobar pneumonia can be prevented. I am not at all sure that, even if possible, such would be a desirable achievement. As before stated, it is a source of gratification to find the early and frank consolidation of a single lobe of the lung. Not knowing all the secrets of biological chemistry, we may not explain why this early consolidation is desirable. However, after the involvement of, let us say, the lower lobe of the right lung, one feels uncomfortable to find the evidence of approaching consolidation in one of the lobes of the left. It is just at this particular juncture that it seems to me important to delay or, if possible, to prevent the consolidation of the second lung. It would be very difficult to prove that one has actually prevented pulmonary consolidation when the process has begun, and yet I am confident in the belief that this is sometimes actually accomplished, and I feel certain that consolidation can be postponed.

Let us suppose we have reached the fifth day of the disease, with the middle and lower lobes of the right lung involved, the patient showing markedly the depressing effects of the toxemia, the action of the heart requiring us to use strychnine freely, when physical examination reveals a marked and somewhat abrupt decrease in the vesicular breathing in one of the lobes of the left, with slight loss of resonance upon percussion; examination an hour later reveals the increase of these physical signs with breathing

of the broncho-vesicular character, or even a quality that merely suggests bronchial breathing. Now, if we translate these physical signs into the concept of the physical condition which they represent, we will find that the tissues of the lungs are relaxed, many of the air cells in a state of atelectasis, marked engorgement with blood, cloudy swelling beginning in the epithelial lining, and inflammatory exudate actually taking place. In other words, here is the early stage of congestion. Doubtless there will soon be consolidation, and double pneumonia on the fifth day is likely to result in death. If the process in the left lung can be postponed for twenty-four hours, there is the possibility of beginning resolution in the lobe first attacked and, therefore, the prospect of more available breathing space; or, if it is impossible to prevent the oncoming consolidation in the second lung, it may be possible to lessen the extent of involvement in the lobe and thus spare to the patient available breathing space.

There can be no question, it seems to me, about the desirability of this postponement of the consolidation of the second lung, and in the limitation of the pulmonary area involved in the process. The question is, can it be accomplished? I repeat that I believe it can be. To begin with, we should take advantage of the constitutional measures already described. It is a good time to give an additional dose of calomel, to press the hot foot-bath, to support the tissues by an increase in the strychnine, and then to resort to the local measures that may decrease the pulmonary congestion. The most useful measures are to withdraw from four to six ounces of blood from the arm, and then to use dry cupping very thoroughly over the threatened area. By dry cupping is not meant the usual feeble efforts that often parade under that name. It is intended that the cups should be large, that the suction should be strong, and that a very decided impression should be made upon the soft tissues. A few hours after that procedure the auscultatory sounds over the newly-affected area will be better rather than worse, and we usually find a more generous vesicular element in the breathing than was present before. Where this slight bleeding from the arms seems inexpedient because of a violent prejudice in the family against it, I have seen a fairly-satisfactory result follow the application of eight or ten leeches applied closely together along the posterior axillary line. The larger withdrawal of blood is almost invariably followed by the cessation of the advancing consolidation, but there are undoubtedly objections to a very generous venesection, and yet I should not hesitate to withdraw from twelve to sixteen ounces of blood where the congestion is sudden and intense, and by this measure I am sure that I have seen several lives preserved. But that is not the plan now under consideration. The idea, as has been stated, is to prevent a new focus of consolidation, and realizing that we may have to repeat the maneuver within a few hours, it is worth while to conserve the blood by withdrawing no unnecessary amount. Experience teaches that a small bleeding, associated with the cupping and the constitutional measures described, will often prove sufficient. The special hour in the course of the disease in which this treatment seems to be most desirable is when the crisis may reasonably be expected to appear within forty-eight hours, and when we feel that, if within the next twenty-four hours the second lung becomes seriously involved, the right heart will fail and the patient lose ground. Just here I urge that the adequate bleeding and prompt and thorough dry-cupping, to be followed by liberal inhalations of oxygen, will tide the patient over the imminent danger and afford time for expected crisis.

Occasionally we see one of those odd cases that Wunderlich called "wandering pneumonia," in which consolidation appears first in one lobe, then in another, until, in its career, all lobes of the lungs may sooner or later be involved. I have actually known one lobe to be attacked the second time, and have seen these cases continue even into the third week. In these cases it is my firm belief that I have seen the approaching consolidation of one lobe aborted—the process retiring from the lobe subsequently to appear in another lobe that had hitherto given no sign of involvement. Admitting the possibility of misconception as to the real facts of the case, nevertheless one is privileged to draw some conclusions from repeated clinical experience in carefully studied cases.

Lobar pneumonia is a disease that needs the almost constant presence of the attending physician. This, of course, does not apply to the simple cases that have from the first a tendency toward recovery; but in the grave cases which give us a large percentage of mortality. If we are to attain success it must be by constant vigilance and attention to small things. A definite idea of what is sought to be accomplished is usually all that is needed to enable the physician to gain the consent of the patient and friends to take the necessary steps in the treatment. There are still many people who object to the loss of a drop of blood if it can be avoided; and, surely, there is reason to be suspicious of a man who loudly proclaims that he believes in treating pneumonia by blood-letting. I am sure that that doctrine should pass, if it has not, into deserved oblivion. The plea here made is not for the treatment of pneumonia, as a disease, by blood-letting, but for the postponing of one of the local manifestations of the affection and thereby assisting Nature to bring about the favorable crisis and to allow the patient to recover.

The question of counterirritation deserves careful consideration. It is a form of treatment now generally discarded, and yet there is one particular condition in which I believe it to be of use. I refer to cases in which there is delayed resolution. Several times I have seen immediate improvement take place in a lobe that had

resisted other measures of treatment after the application of a large fly-blister. Several times when it seemed to me that softening of the lung tissue was inevitable, complete recovery was apparently brought about by this old-fashioned method. I am convinced that we are not yet in a position to dispense absolutely with counter-irritation in pneumonia. Finally, experience teaches me that the great fatality of senile pneumonia is mostly dependent upon the unusual toxemia present in these cases, because of the inadequate functional activity of the organs of elimination. If, with stimulating, we at the same time sweat the patient and assist hepatic and renal secretion by proper means, our results will be strikingly better.

ON THE ROLE OF THE PROSTATE GLAND IN GONORRHEA.

BY FREDERIC BIERHOFF, M.D.,

OF NEW YORK;

ASSISTANT ATTENDING SURGEON, DEPARTMENT OF GENITO-URINARY DISEASES, UNIVERSITY AND BELLEVUE MEDICAL COLLEGE; FORMER ASSISTANT, DEPARTMENT OF GENITO-URINARY DISEASES, BERLINER ALLGEMEINE POLIKLINIK, BERLIN, GERMANY.

THE crux in the treatment of gonorrhea is the extension of the inflammatory process to the posterior urethra, and there is, perhaps, no other condition so frequently responsible for the persistence of a gonorrheal urethritis as an involvement of the prostate gland. In spite of every precaution, on the part of both physician and patient; in spite of the use of the most approved methods of treatment, some of the cases which enter treatment as uncomplicated cases of anterior urethritis will drag on, week after week, for months, or sometimes even years, with varying degrees of discharge, and still showing gonococci. One form of injection, or of internal treatment, is tried after another, and, in the end, the discharge may be reduced to a mere trace of moisture, and the patient be discharged as apparently cured, or he becomes disgusted, and gives up all treatment, trusting to good fortune and to Nature for a cure. In either case it is seldom long before a fresh outbreak of purulent, gonococcus-bearing discharge appears, following upon indulgence in alcoholics, or intercourse, and then a "fresh gonorrhea" is diagnosed, and the same round of treatment repeated.

Wherein lies the cause of this protraction of the disease; why does it occur; how may it be avoided, and, finally, how may the disease be cured? In the correct answer to these questions lies the entire secret of the success or failure of the treatment.

If we follow the course of a series of cases, treated either by internal, or by direct, urethral medication, we find that, in a large percentage of these, the process extends to the posterior urethra. Different authors give varying percentages of posterior urethritis; thus Leprevost (1884) saw it in one-sixth of his cases, Eraud (1886) in 80 per cent., Jadassohn (1889) in 87.7 per cent., Letzel (1890) 92.5 per cent., Rona (1891) 62 per cent., Phillipson (1891) 86.6 per cent., Rona (1892) 90 per cent., Dind (1892) 93 per cent., Ingria (1893) 59 per cent. These differences in percentages are, no doubt, due to different methods of examination employed to determine the existence of a posterior urethritis, as Finger points out. The last-mentioned, in his book, stated that he has found it present in 63 per cent. of his private patients, as against 82 per cent. in his dispensary clientèle. In a more recent publication (1900) he states that this complication occurred in about 40 per cent. of the cases which he had treated with protargol, and in 27 per cent. of those treated with largin; or, together, an average of 33.5 per cent. Frank (1900) met it in 32.25 per cent. of his Poliklinik cases of gonorrhea.

If we consider the anatomy of the posterior urethra, we find that we have to deal with a far shorter canal than the anterior, and one which, unlike the latter, is not rich in lacunæ and glands. In fact, as Frank states, and to all intents and purposes this is true, it is connected only with two larger sets of glands, Cowper's and the prostate. Therefore, while in an anterior urethritis the numerous lacunæ and glands are the most frequent seats of protracted inflammation, the process must, in posterior urethritis, in the greater proportion of cases, become a cowperitis, or prostatitis. Of these the former is a relatively rare complication, the latter, on the other hand, very common. Finger states: "A catarrhal, glandular prostatitis is regularly a complication of acute posterior urethritis." He might have added that this is the condition also in the subacute and chronic cases. Sigmund is of the opinion that every gonorrhea of several weeks' duration is followed by a swelling of the prostate, at times marked, which does not subside after the cure of the blennorrhea. Montagnon and Eraud state that infection of the prostate is present in 70 per cent. of the cases of urethritis posterior. Von Frisch says: "It is most probable that hardly a single acute posterior urethritis runs its course entirely without implication of the prostate gland." Goldberg (Köln) believes that one-third to one-half of all gonorrheas affect the prostate. Pezzoli found the gland affected in 80 per cent. of his cases, Colombini in 28 per cent. of his acute and 40 per cent. of the subacute or chronic gonorrheas. Frank states that by far the largest number of chronic and latent gonorrheas are due to foci of infection in the prostate. More recently he reports the result of a series of investigations covering 210 cases of posterior urethritis. In all of them, or 100 per cent., there were evidences of prostatic involvement.

Of 151 cases of posterior urethritis coming under my own notice (in part during my service at the Berliner Allgemeine Poliklinik, in part occurring in private practice) I found the prostate involved in the entire 151 cases, in other words, in 100 per cent. Of these cases, 111 came under treatment with the prostatitis already present; in

40 it developed during the course of the treatment.

Of the 151 cases, those which had been previously treated numbered 71 cases; untreated, numbered 47; unknown whether treated or not, 33. The disease was a first attack in 64 cases; second, or further attack, in 70; unknown, in 17 of those examined.

This complication is said to occur usually about the third week of a gonorrhea. In this series of cases it had lasted less than one week in 32 cases; one to two weeks in 25; two to three weeks in 19; three to four weeks in 12; over four weeks in 51; unknown duration in 12. Therefore, in 57 cases, or almost 38 per cent., it occurred within the first two weeks, and in 32, or over 21 per cent., within the first week.

Causes.—Various theories have been advanced to explain the occurrence of this complication. The opponents of local treatment claim that it occurs through the forcing backward of the germ-bearing discharge into the posterior urethra by the fluid injected. If that, and that only, were the cause, then among those cases untreated locally, or treated by internal medicines alone, we ought never to meet with a case of posterior urethritis. But we do.

In the cases I quote, the treatment had been local antiseptic in 17 cases; local astringent in 21; local, of unknown nature, in 15; internal alone in 10; internal and local antiseptic in 3; internal and local astringent in 5; untreated in 47; unknown whether treated, or not, 33. Thus 57 had been untreated, or treated only by internal medication, and 61 treated locally alone, in various ways, or locally and internally. In other words, the balance was fairly even.

It seems to matter little what form of treatment is employed (though I incline to the view that, with the proper application of the newer gonococcicide remedies, the percentage of cases which develop posterior urethritis and prostatitis will be much reduced, and that, while the form of treatment may have a bearing among the causative factors, it is not the sole cause, nor even the principal one. That must be sought elsewhere.

Any condition or measure which produces congestion of the deeper urethra, or which forces the living germ into the posterior urethra and the ducts of the prostate, favors the development of posterior urethritis and prostatitis. Among those usually given are excesses in drink or in venery; severe, forced movements, such as long marches, horseback riding, bicycling, constant sedentary occupation. Straining in lifting, etc.; local irritants, such as forcible injections of astringents; catheterism, passage of sounds, etc. In considering the causes, however, we must differentiate between the exciting and the predisposing. The exciting is in all cases the entrance of the gonococcus into the posterior urethra and prostate; the predisposing, any condition (usually a congestion) of these parts which favors the development and multiplication of those germs which have entered them, with the causes which brought this condition about.

The infection may spread either by a direct extension of the inflammation to the posterior urethra, and thence, by way of the ducts of the prostate, to the gland itself, or by way of the circulation or through the lymphatic system. Of these the first is considered to be by far the most frequent. How great a rôle the second and third play must still be proven.

While it is true that the compressor urethræ muscle separates the urethra into two divisions and forms a natural barrier to the regurgitation of pus from the anterior into the posterior portion of the canal, I doubt whether it offers an insuperable obstacle to the direct extension of the infectious process along the mucous membrane. The principal factor in the prevention or the permission of extension of the process into the posterior urethra is, I believe, not chiefly the muscular action of the compressor, but the condition of the urethral membrane at and posterior to it prior to and during the existence of gonorrheal urethritis anterior. If there has been an inflamed or congested condition of this portion of the canal prior to the infection of the anterior urethra, I believe that the process will almost invariably extend over into the posterior urethra and thence to the prostate, and this irrespective of the form of treatment that may be employed. Naturally, too, if under these circumstances instrumentation be employed without gonococcicide precautions, infection of the posterior urethra must almost invariably occur. Anything, therefore, which favors or causes congestion of the urethra increases the suitability of the culture-medium for the development of the gonococcus and invites direct extension of the process along the surface of the congested mucous membrane or extension by way of the interepithelial spaces, or subepithelial lymph-channels, to the membrane of the posterior urethra.

In the prostate, too, as gonorrheal prostatitis regularly follows the development of a posterior urethritis, any pre-existing congestion opens the way for an extension to it of the infection from the urethral canal. This I believe to be the true inwardness of the influence of the numerous causes related by writers upon this topic, *i. e.*, they produce congestion, either acute or chronic, of the urethra, or the prostate, or both. But just as the existence of congestion of the prostate is potent as a predisposing factor in the development of gonorrheal prostatitis, so, also, is the presence of foci of catarrhal inflammation in the gland. In the examination of the prostate in a large number of cases of gonorrhea before the institution of any treatment and irrespective of whether the process involved the anterior or posterior urethra, and also in numbers of patients free from gonorrheal disease, but presenting other symptoms referable to the genito-urinary system, and in still others apparently well and presenting no symptoms whatever referable to these organs, palpation of the gland has led me

to believe that a large percentage of adult males, whether they have suffered from gonorrhea or not, present catarrhal changes (follicular or endoglandular prostatitis) which are distinctly appreciable to the examining finger. Palpation of these suspected glands reveals localized areas of distinct softening in the otherwise normal tissues. Pressure thereon produces a thin, milky to yellowish-milky fluid, which has the characteristic odor of prostatic fluid, and under the microscope shows the characteristics of this fluid, *plus* a few cylindrical epithelia, and at times isolated leucocytes. These foci of catarrhal change, chronic in character, form a *locus minoris resistentiæ* and offer the best site for the further development of the gonorrheal process. Similarly, in those of my previously-examined cases in whom, later, a posterior urethritis developed, as also in those in whom it was present and who had not been previously examined, the foci of prostatic infection were regularly found to be these areas of softening, and massage thereof brought gonococcus-bearing pus in the prostatic fluid to the surface. Finally, endoscopic examination in a number of the non-gonorrheal cases which presented symptoms referable to the urethra revealed a more or less congested, exquisitely sensitive mucous membrane over the entire canal, but more marked in the deeper portions.

Questioning of the individuals examined invariably revealed a history of preceding addiction to masturbation, or coitus interruptus. These two practices I believe to be the chief factors in the production of areas of catarrhal change in the prostate and chronic congestion of the posterior urethra, and these changes, again, to be the condition which predisposes their bearers to the extension to the prostate of any gonorrheal or other infection of the uretha which they may acquire. The form of treatment employed I believe to be of far less importance than the existence of these factors prior to the infection of the individual, though I firmly believe—basing this view upon the experiences of Finger, Frank and others, in addition to my own—that the rational use of the modern, gonococcicide remedies, notably protargol, is likely to greatly lessen the percentage of those who develop posterior urethritis or prostatitis. The sooner the gonococci are destroyed, the less the danger of the involvement of the posterior urethra and prostate.

The progress of the infection I believe to be as follows: Involvement of the anterior urethra; spread of the infection past the compressor through direct extension along a chronically-congested mucous membrane of the bulbous, membranous and prostatic urethra; involvement by direct extension of the ducts of the previously congested prostate; extension to the walls of the gland or to the interstitial connective tissue separating the individual lobules, or even to the periglandular connective tissue.

Varieties—These as usually given (Finger, Albarran and others) are the catarrhal, follicular, parenchymatous, and prostatic phlegmon of the acute type; further, chronic prostatitis. They do not always occur singly as typical examples of these varieties, but are frequently associated; or the one variety may merge into another.

Diagnosis—The extension of the gonorrheal process from the anterior to the posterior urethra and prostate may occur in an acute form, with decided symptoms, or its onset may be so gradual and insidious as to present no physical symptoms whatever and escape all but the most careful observation. In the former case there will be increased frequency of urination, accompanied by a greater or less degree of tenesmus. It may be preceded by a chill and accompanied by febrile movement. If the vesical neck and sphincteral margin be involved, as seems often to be the case, there may be the discharge of a few drops of blood at the termination of micturition. There may be a feeling of weight, discomfort, pressure, or even pain in the perineal region, but this is not necessarily present, however. There may be in those cases accompanied by decided increase in the size of the gland well-marked interference with micturition or defecation or both. These cases are usually of the parenchymatous or interstitial type.

In the greater proportion of such cases, however, the onset is more insidious; at times, even, as stated before, no appreciable symptoms whatever are presented. In most the first condition or symptom which presents will be more or less-marked turbidity of the last portion of the urine. In some (17 of the 151 reported in this series), however, the urine is to all appearances clear. In others the turbidity may be so slight as to escape all but the most careful scrutiny. The turbidity on examination will be found to be due to pus, and if the sediment be examined microscopically it will be found that there are present extracellular and intracellular gonococci. (I shall not here go into the merits or demerits of the two-glass test as against the three-glass test except to content myself with the statement that I have found that the former is sufficient for the determination of the involvement of the posterior urethra, provided the patient be instructed to void almost all of the urine into the first glass.) There may be nothing besides this slight turbidity of the second urine—except, perhaps, the persistence of gonococci in the urethral discharge for an abnormal length of time—to draw attention to the prostate.

Upon the introduction of the examining finger into the rectum, the gland will be found more or less changed. It may be enlarged, but not necessarily symmetrically, as one or other lobe may be more involved. In our cases, it was more frequently the left. The consistence of the gland may be changed. In the catarrhal type there will be found areas of distinct softening in an otherwise apparently-normal organ. In the follicular or parenchymatous type there are likewise softened areas, but these are surrounded by a zone of thickening or infiltration. The intersti-

tial type is usually marked by an appreciable symmetrical enlargement of the entire gland, which feels tense and elastic and is sensitive to the touch. During the later stages of this type, areas of softening develop. It is usually in this type that suppuration occurs, if it appears at all. Palpation is not necessarily painful, aside from the feeling of discomfort which the introduction of the finger into the rectum causes. In the acuter forms, however, especially in the interstitial, the gland is usually painful, becoming at times exquisitely sensitive. Goldberg (Köln) draws attention to the fact that, while in tuberculous prostatitis the softened areas are exceedingly painful on pressure, they are painless in the gonorrheal variety. Pressure upon or massage of the softened areas causes some of the contents, the more or less altered prostatic secretion, to be expelled into the ducts, and thence into the urethra, whence it usually passes to appear at the meatus. It may, however, regurgitate into the bladder to be later expelled on urination.

The method of examination which has given me the greatest satisfaction, and which I believe to offer the greatest certainty that the prostatic fluid is obtained unmixed with urethral discharge, is as follows: The patient first empties the bladder, passing the urine (in two unequal parts, of which the first is the larger) into two clean glass vessels. Hereupon the anterior urethra is thoroughly irrigated, following which the posterior part of the canal is flushed; in neither case is a catheter employed, the fluid being forced under gentle pressure into the bladder. For this purpose the hand-syringe has given me greater satisfaction than the irrigator, it being possible instantly to vary the amount of pressure. The patient again empties his bladder, this time of the injected fluid. We now proceed to gently massage the prostate, catching up with a sterilized platinum loop some of the prostatic fluid which appears at the meatus. Of this slides are then prepared for examination. Care should be taken not to make any stripping movements along the penis, in order that no urethral secretion may be pressed out of the crypts and glands to mix with that from the prostate. The free hand only steadies the penis and does not strip it. Should no fluid appear at the meatus, the anterior urethra is again irrigated, and the patient instructed again to empty the bladder. Almost invariably it will be found that he will pass a small amount of urine, collected during the interval. This is caught up in a clean vessel, centrifuged, and the sediment examined for pus and gonococci. If care be taken to irrigate the urethra, both before and after massage, and to avoid any violence in the massage itself, the danger of any ill effects from the procedure is very slight, indeed. I have, however, frequently seen carelessness, or lack of skill therein, followed within twenty-four hours by involvement of the seminal vesicles, epididymis, or testis.

In the examination of the cases reported here, various methods were employed, *viz.:* Examination of the discharge obtained after the patient had emptied the bladder and without preceding irrigation; examination after the emptying of the bladder, followed by irrigation of the anterior urethra; examination after urination, followed by irrigation of the entire urethra; examination after urination followed by the insertion of the endoscopic tube to the urethral bulb, thorough drying of the canal at the floor of the tube, massage, removal of the expressed fluid directly from the bottom of the tube; lastly, urination, irrigation of the entire urethra, insertion of the endoscopic tube, massage, and examination of the fluid thus obtained. The results obtained by these different methods were practically the same, and, as a result, I have adopted the one just described in full.

The next step is the examination of the secretion itself. To the eye it may be watery, milky, bloody, frankly purulent, or any combination of these. The odor is that of semen, since this derives its characteristic odor from its admixture with the prostatic secretion. Examined in the fresh state, it contains in the catarrhal type of prostatitis a few lecithin granules, small globules of fat, cylindrical epithelia, cell-detritus, and at times isolated leucocytes. In the parenchymatous form, the solid contents are increased, but most notably the leucocytes. There may be found, also, a few erythrocytes. In the interstitial type the erythrocytes are more numerous than in the preceding forms, while the discharge from the prostatic abscess is pure, frank pus. Stained, the specimens show in addition intracellular or extra-cellular gonococci, or both, with at times the presence of other bacteria.

In this series gonococci were present in the prostatic secretion in 127 cases; gonococci and other bacteria in 7; diplococci, but not positively gonococci in 4; other bacteria in 4; no germs in 9. In making these examinations, the watery solution of methylene blue was used, and answered all purposes. Where any doubt existed, Gram's method was employed.

Treatment.—This may be divided into prophylactic and curative. Prophylactic treatment consists of the attempt to rid our patients of the source of the trouble, the gonorrheal urethritis, in the shortest time. To do this, I believe our most valuable and reliable method is the irrigation of, first, the anterior, then the entire urethra, at first twice, later once daily, with a warm one-half per cent. solution of protargol, without the use of a catheter. This is, of course, only of use in cases of anterior urethritis. Care must be taken to avoid forcible injection. In addition to this, bed rest where this is possible, bland, yet nutritious diet, attention to the bowels, avoidance of all alcoholic drinks and of sexual excitement. I have seldom found blennorrhetics or narcotics necessary when using the gonococcicide remedies.

Should the patient come under treatment with an already turbid second urine, or should pros-

tatitis develop during the course of treatment, then irrigations alone will not cure the case. (It is true that it sometimes happens that, in cases where the prostate is involved, the urethritis appears to become cured and the discharge to diminish to a mere trace, or even to disappear; but, as soon as the patient indulges in coitus or in alcohol, there is a reappearance of purulent urethral discharge.) Therefore some other method must be employed, and this is massage of the affected gland, in addition to irrigation of the urethra. In massaging, I prefer to employ the finger, rather than any instrument, such as that of Feleki, because (1) I find it preferable to locate the foci of disease and to massage these, rather than to apply the treatment indiscriminately to the entire gland and the surrounding parts; (2) the amount of pressure to be applied can be gauged better with the finger; (3) I believe the danger of injury to the patient to be less.

The minutiæ of the proceeding I shall not describe, as they are known to most of us. I would repeat, however, that I think it wise in every case to precede the massage by an irrigation of the entire urethra, without the catheter; also that the treatment should be gently applied. Brusque or unskilful handling may, and frequently does, bring on complications in a few hours. But, although gentle, the massage should be none the less thorough, and continued until pressure expels no more secretion. Then the entire urethra must again be irrigated. At times no discharge appears at the meatus after massage, but flows back into the bladder. We may satisfy ourselves with regard to the efficacy of massage, in these cases, by an irrigation of the entire urethra. The fluid, after having passed into the bladder, is voided by the patient into a glass vessel. Here it will be found to have become distinctly turbid, and examination will show this turbidity to be due to the prostatic secretion.

Massage should be applied in every case of prostatitis which is not complicated by acute, general symptoms, such as decided febrile movement. Where fever is present, irrigations alone should be employed until its subsidence. Even prostatic abscesses which have opened into the urethra may be definitely cured by this procedure, though at times it becomes necessary to incise from the perineum. In the interstitial, or phlegmonous forms of the disease, it is well to follow Goldberg's advice, *i. e.*, better to begin massage a little late than too early.

Massage should always be accompanied by treatment of the entire urethra by the physician. It may be employed daily or less often according to the acuteness of the process and the ability of the patient to bear it. I am in the habit of employing it daily or every second day in sessions of not over two minutes. The treatment of the prostatitis should be continued, even after the definite disappearance of gonococci, until this also is cured.

An additional aid in treatment is the use of the rectal cooler, or rectal psychrophore. In the catarrhal type cold water may be employed to advantage with this instrument; in the follicular and interstitial forms, preferably as hot as the patient can agreeably bear it, in one or two sittings of from ten to fifteen minutes daily. In the later stages, as in the more protracted catarrhal cases, alternating hot and cold water during the sitting; the electrical current may also be of benefit. The urethral psychrophore should, I believe, never be employed until all micro-organisms have definitely disappeared from both urethral and prostatic secretions. Faradic electricity and massage may be combined by means of an ingenious arrangement attached to the massaging finger, constructed by Hogge, of Liege, or its modification by Frank, of Berlin.

In addition to local, general treatment is also indicated. This consists of care to avoid exposure or chilling, attention to diet and to the bowels, warm hip-baths at night; and especially tonic treatment, as patients suffering with posterior urethritis and prostatitis seem especially prone to become neurasthenics. In addition to the usual tonic drugs, hydrotherapeutic measures, general massage, and judicious exercise are of value.

Frequently, after the disappearance of the gonococci, a slight, mucous, or muco-purulent urethral discharge persists for a time. Microscopically this is found to consist principally of epithelia and mucous shreds, with a few, degenerated pus-cells. Examination with the endoscope shows reddening of the mucous membrane, with a degree of infiltration varying in extent and character according to the length of time during which the gonorrheal stage has persisted; the glandular orifices, also, will frequently be found reddened and pouting. Should a secondary infection with other bacteria occur, irrigations with bichloride-of-mercury solution are indicated. Where an aseptic, mucous discharge continues, application of the usual astringent remedies, with a course of dilatation of the infiltrates according to their degree of severity, are indicated.

Complications—From this condition any of the other usual complications of gonorrhea may arise. Most frequent, however, are seminal vesiculitis, funiculitis and epididymitis. Unfortunately, so little attention has been paid, until recently, to the relation of the prostate to gonorrhea, that reliable statistics are few with regard to the relative frequency of epididymitis as a complication subsequent to, or coincident with gonorrheal prostatitis. Frank reports 17 cases as occurring among 651 of his Poliklinik cases of gonorrhea, or 2.5 per cent of the total. Compared with the 12.5 per cent which Finger in 1896 stated was the percentage of those who presented this complication among 1,000 of his Poliklinik cases of gonorrhea, it will be seen that the proportion is 5 to 1 in favor of the modern methods of treatment. Finger, however, makes no mention of the involvement of the prostate in his cases. Of Frank's 651 cases 210 were complicated by a pos-

terior urethritis (in each one of the 210 a prostatitis), and, as this complication regularly precedes the development of epididymitis, we may figure that in his series of 210 cases of prostatitis involvement of the epididymis occurred in 17 or 8.2 per cent.

In the acuter forms of gonorrheal prostatitis, there is regularly an involvement of the neck of the bladder; and the increased frequency of micturition, as also the marked tenesmus, may entirely mask the prostatic condition. Hence it is that, in view of the turbidity of the urine, the frequent micturition and the tenesmus, the diagnosis of gonorrheal cystitis is erroneously made, when examination of the prostate would at once reveal the true nature of the complication. I doubt whether a case of gonorrheal cystitis ever occurs in the male without involvement of the prostate, and I also believe that the acute interstitial or phlegmonous type is regularly accompanied by more or less inflammation of the vesical neck. In the male no condition should ever be diagnosed as gonorrheal cystitis without a previous careful examination of the prostate.

Prognosis.—This is in the main good. Naturally, the sooner a case of posterior urethritis is diagnosticated and the involvement of the prostate determined, the sooner can a complete cure be effected. It is not at all infrequent in the milder cases of the catarrhal or endoglandular type to find that a few applications of massage will serve completely and definitely to cure the gonorrhea. The older the case the more deeply will it have been possible for the gonococci to penetrate the tissues, the greater is the interstitial exudation, and the more resistant will it prove to treatment. Therefore, in the follicular type, where the walls of the alveoli are more or less involved, it is not unusual to find that, although the gonococci may disappear within a reasonable time, the prostatitis, non-gonorrheal now in character, may persist for months. In these cases it is not infrequent for the urethritis to disappear entirely and the prostate still to show points of infiltrative change, the prostatic secretion, however, being entirely free from gonococci and remaining so, in spite of the application of all the usual tests, and containing only isolated leucocytes, in addition to some degenerated epithelia, suspended in a slightly-increased, but otherwise normal secretion. In the interstitial form, as in the follicular, the case is apt to drag over a period varying from several weeks to months. In the phlegmonous variety much depends upon the point at which the pus discharges. The most favorable course is to have the abscess rupture into the posterior urethra; rupture into the rectum gives us a more tedious and dangerous condition to deal with; most dangerous is its opening laterally, with consequent involvement of the pelvic cellular tissues. Such cases may end fatally.

Much has been said of the tendency for supposedly-cured cases of gonorrheal prostatitis to recur. No case should be discharged as cured until the prostate feels normal to the examining finger; the prostatic fluid, as well as the urethral scrapings or shreds, free from gonococci, and the first of these normal in appearance, and the last two found to consist of epithelia and fibrinous or mucous filaments. These conditions must remain unaltered upon the application of the various provocative tests, *i. e.*, alcohol, irritant injection, the passage of a good-sized sound, and, lastly, coitus with condom. Where, as is sometimes reported, gonococcus-bearing discharge appears after months of freedom from all urethral and prostatic symptoms in cases that had been properly treated and tested before being discharged, I believe the cases to be fresh infections and the denials of intercourse by the patients to be wilful lies.

In conclusion, I desire to express my sense of deep obligation to Drs. Ernst R. W. Frank and Arthur Lewin, of the Berliner Allgemeine Poliklinik, for their kind permission to make use of those of the cases which came under my observation during my service in that institution, and to the former for his valuable help and counsel in the study of the material.

717 Madison Avenue.

THE NEUROTIC ELEMENT IN INFANTILE ECZEMA.

BY JEROME KINGSBURY, M.D.,
OF NEW YORK.

ECZEMA is probably the most common, as well as the most troublesome affection of the skin that is met with in children under the age of five. At this period of life it plays a greater and more important rôle than at any other, and if negligently or improperly managed it has a strong tendency to become chronic and to persist for years. It is often so difficult to cure and causes so much agony to the little patient, to say nothing of the anxiety and annoyance to which the family must be subjected, that it is a mistake to class it, as is too frequently done, among the lesser ailments of childhood. "Only an eczema" will sometimes prove a most rebellious and annoying disease to handle and a favorable prognosis should always be withheld until a case has been under observation for some time.

During the past few years writers in the medical journals have by no means neglected the subject of infantile eczema, but the methods of treatment advocated for this most troublesome and, I might say, serious disease, have in the majority of cases been purely local. Ingenious measures for restraining the hands of the little sufferer have been suggested, and elaborate and cleverly-devised masks and bandages upon which some favorite ointment may be so spread that it will be kept in constant contact with the eruption have from time to time been advocated. But this more or less heroic treatment, for obvious reasons, cannot always be employed; and even when it is carried out under the most favorable surroundings, recovery is often very slow,

and one reluctantly realizes that a strait jacket and medicated lard will not cure all eczemas.

It is true that when the patient is deprived of the use of his hands and can no longer scratch, we can generally control the spread of the eruption and invariably eliminate the impetiginous element. It is also true that the condition of an eczematous eruption will improve when a properly-selected ointment can be satisfactorily applied. But eczema, unfortunately, is not a local disease and these measures merely modify local manifestations that are but secondary to some nerve or capillary disturbance. They cannot control the disease itself. To do this we must study the possible etiological factors and predisposing and exciting causes, and avail ourselves of such therapeutic aids as may be rationally suggested thereby.

It is useless to look for a specific for this protean disease for there is none. No one preparation no matter how "good for eczema" or how satisfactory it may have been in certain reported cases will ever give uniform results in practice. As Sherwell[1] very aptly remarks: "There is per se nothing 'good' for an eczema, any more than a color, any one or more colors, are good for a picture."

The eczemas of childhood have been divided by Unna into three classes—the tuberculous, the seborrheic, and the neurotic. A sharp line of demarcation, however, cannot always be drawn between these forms of the disease. One often laps over upon the other. The impetiginous element or so-called tuberculous eczema is frequently engrafted upon a skin in which erythematous, papular, or seborrheic lesions previously existed. Nerve irritation, or disturbances of the nervous system, not only serve as important etiological factors of the disease, but will to a considerable extent intensify the severity of an already existing eczematous eruption of whatever type.

Although not inclined to admit the existence of a purely neurotic eczema, it would, we feel, be admissible to recognize by this designation, at least for clinical convenience, that form of the disease in which the nervous element is most marked or where it seems to be the prominent exciting or predisposing cause of the eruption. A clear understanding and appreciation of these causes will aid us very materially in the treatment.

Generally speaking, the neurotic elements that contribute to make infantile eczema the formidable disease that it frequently is are caused by reflex neurosis, and can be divided into gastro-intestinal, sexual, and local nerve irritation.

That type of nerve strain and exhaustion so often observed in adults suffering with eczema, is seldom, if ever, encountered in children under five years of age.

Of local nerve irritation, that of teething infants is the most strikingly evident. Hebra denied that this has anything to do with the eruption, but it is a factor of no small importance. It may be true that dentition itself never produced a true eczema; still there is no question that in many cases with the eruption or rather attempted eruption of each new tooth an eczema has become greatly aggravated. Occasionally, indeed, in such cases there has been a recurrence of the disease in a patient supposed to have been cured.

Dentition, however, plays a much less important rôle than iritation from the alimentary canal. This is probably the most frequent factor in the majority of cases, for the disease often starts in children one or two months old. The catarrhal condition of the entire gastro-intestinal tract caused by the imperfect and faulty feeding, of which infants are too often the victims, is much oftener the cause of the skin trouble than is physiological dentition.

The quantity and quality of food frequently administered to infants is sometimes almost beyond belief. When questioned as to what nourishment a child of eighteen months, suffering with extensive eczema, is receiving, the most frequent answer that I have received from the mother is: "Oh! He gets the same food that we do," and they will often add, "and he is always hungry, too." Then with a little cautious questioning the information is generally elicited that our little patient is in the habit of dining at the table with the family where his share of the meal will consist of all the steak, corned beef or sausage with potatoes or cabbage that he will eat. This will be followed by a cup of tea or coffee (always a large one and sometimes two) or a "sip" of beer. The time between meals is employed by munching a cracker, doughnut, or whatever is known by experience to keep him most quiet.

Stomachs and intestines that have been abused and overloaded for months cannot be restored to health in as many days. Our duty does not end with advising a proper dietary and the administration of calomel or gray powder. Such cases must be under observation and have judicious regimen as well as medication even after the eruption has entirely disappeared.

Nor does the breast-fed infant always escape. Too often is the mother's milk of unsuitable quality and it is just as necessary to correct her habits and administer suitable medication as it is to treat the child. The large amount of tea sometimes taken by women nursing children with eczema should be reduced to the minimum and the beer and ale that they had been consuming with the mistaken idea that they were improving the quality of their milk should be absolutely prohibited.

The possibility of pin-worms in the rectum and occasionally in the vagina should be considered and a careful examination of the penis, and also of the clitoris, should always be made.

The influence exerted upon the eruption by a phimosis or by masses of calcified smegma that bind the prepuce tightly to the glans can only be realized when we observe the marked improvement that will invariably follow when these con-

[1] "On the Effect of Topical Applications of Excessive Strength and Improper Diet and Hygiene in Prolonging and Causing Skin Diseases in Infants and Young Children," Medical Record, Jan. 5, 1901.

ditions are corrected. Not infrequently the clitoris will be found under some constriction which should be removed.

Very often parents are unwilling to have their babies circumcised and one naturally feels a certain hesitancy in advocating an operation upon the genital organs for the relief of a disease of the skin, lest to the lay mind it might suggest the methods of charlatanism or might needlessly be foisted upon a patient who has troubles enough as it is.

In many cases when there is no constriction of the prepuce an operation can be avoided and the condition relieved by the introduction under the foreskin of a well-oiled probe that can be swept around the entire surface of the glans and the adhesions broken up, after which the prepuce can be retracted and the smegma cleaned out. In cases, however, where there is a marked constriction, and where the foreskin cannot be retracted, a circumcision should not only be advised but insisted upon. I am convinced by observation of many cases that it is the best course to pursue in the interest of the sufferer.

In all cases the necessity for the removal of the exciting cause is clearly indicated, not only to cure the present eruption, but to protect the patient from attacks in the future. After this has been accomplished the benefit derived from remedies that had previously seemed impotent will often be most gratifying.

MEDICAL PROGRESS.

EYE, EAR, NOSE, AND THROAT.

Amblyopia Due to Bay-Rum Drinking.—The idea has been entertained that wood alcohol was the toxic agent in cases of amblyopia following the drinking of essence of Jamaica ginger and similar preparations, which are often substituted for whiskey. H. MOULTON (Jour. Amer. Med. Assoc., Nov. 30, 1901) has observed the close correspondence of symptoms in cases of poisoning from drinking bay-rum and believes the toxic agent is the same in both cases. Ordinary wood or methyl alcohol is too disagreeable in odor and taste to lead to its ingestion *per se*, but under the name of "Columbian spirits," the objectionable features are removed, so that its use becomes possible and as such it is often an ingredient of the preparation already mentioned. It is important therefore to make a diagnosis from the symptoms, which are at first a gastro-enteritis when the dose is small and coma when it is large, followed by rapid failure of sight, which may improve but soon relapses; contraction of the fields of vision; central scotomata, and sometimes total blindness. These are symptoms of retrobulbar neuritis, but contrary to the usual variety seldom recover. Probably no other substance when swallowed selects for attack with such uniformity the optic nerve and retina as methyl alcohol.

Action of the Pupil in Severe Optic Neuritis.—If one of a normal pair of eyes be covered a slight dilatation of the pupil of the exposed eye occurs. This physiological dilatation has been carefully measured by J. HIRSCHBERG (Berl. kl. Woch., Nov. 25, 1901), who expresses it as averaging 1 mm. in a moderately large pupil of 3 to 4 mm. Sudden complete interruptions of the function of the optic nerve of one side may occur early in the course of an acute inflammation, the ophthalmoscope showing at this time a normal fundus. If now the normal eye be covered the pupil of the diseased side dilates very widely; it does not contract when strong light is allowed to enter the diseased eye but promptly contracts when light enters the opposite or healthy eye. The presence of this abnormal dilatation and only indirect contraction is a positive sign of complete blindness in one eye. In the absence of this reaction some condition other than blindness must be assumed to be present, and hysteria and malingering must then be considered.

OBSTETRICS AND GYNECOLOGY.

Treatment of Abortion.—A terse summary of the recent advances in the treatment of abortion is a boon for which all practitioners may well be grateful. C. B. REED (Medicine, Dec., 1901) lays down the laws of modern practice in a manner which has the merit of being definite and concise, even if somewhat arbitrary. Upon the treatment of threatened abortion he has nothing new to offer. When abortion is inevitable or incomplete, the indication is, of course, to empty the uterus. Before the sixth month the finger may be used in all cases except those in which it is unable to penetrate the os or to reach the fundus; the curette is especially indicated in these latter cases, but may be used, if the operator prefers, in the other cases alone. After the sixth month, the curette is a dangerous instrument, owing to the softness of the uterus, and only the finger should be used. After curettage no tampon is necessary, as the uterus drains better without it. Abortion may be induced or completed by tamponade of the vagina, but after the sixth month tamponade should invariably be accompanied by packing of the uterus, since the organ is by this time so large that the woman may bleed to death into its cavity. Septic processes contraindicate tamponade. The use of the antiseptic douche is absolutely proscribed, inasmuch as it not only fails to sterilize the parts, but actually removes the protective secretions of the mucous membranes. After curettage for septic endometritis, a douche of hot one-per-cent. lysol solution should be used. The introduction of styptics into the uterine cavity is unnecessary and always harmful; iodine is the least objectionable. Upon the use of ergot, the treatment of anemia and of shock, the after-treatment of abortion, and, above all, the importance of asepsis, the author is in accord with the generally-received theories and methods.

Pelvic Arthritis of Puerperal Origin.—The modifications which occur in the pubic and sacro-iliac symphyses during pregnancy render them more susceptible to infection during this period and immediately afterward than at other times. P. A. LOP (La Presse Méd., Nov. 23, 1901) describes the case of a woman who had passed through a difficult labor. In attempting to rise seventeen days after confinement the patient was astonished to find that she could neither stand nor sit; micturition became extremely painful and defecation could be accomplished only with difficulty and solely in the recumbent posture. Vaginal examination revealed extreme tenderness over the sacro-iliac synchondroses with abnormal mobility. There was evidently relaxation and inflammation of the articulations. In addition exquisite tenderness was present at the symphysis pubis, the articulation being enlarged and the vaginal vault exematous. The case was treated by silicate fixation; a double spica of the groin was well tolerated by the patient, who after a short previous trial had objected to a plaster girdle. In order not to misinterpret puerperal pains in the genital region, one should examine not only the pelvic organs, but the articulations of the pelvis. In sacro-coccygeal arthritis tenderness and pain

are in the median line at the base of the coccyx. Coxofemoral arthritis produces pains in the knee and at the heel, as well as at the site of the disease; puffiness of the external periarticular tissues is sometimes observed, with enlargement of the glands in Scarpa's triangle. Uterine displacements and vesical disease must be considered before a diagnosis of disease of the symphyses is made.

Congenital Anteflexion and Sterility.—The prognosis to be given in a case of sterility due to anteflexion is the subject of a paper by A. BOURSIER (Jour. de Med. de Bordeaux, Nov. 24, 1901). The childless state of sufferers from this form of displacement has been variously attributed to the mechanical obstruction to fecundation, metritis, or to both. The persistence of sterility in patients with marked anteflexion and indications of inflammation of the uterus and adnexa may be pretty positively affirmed, especially if, in addition, the uterus presents a very small orifice and conical neck. On the other hand, where the anteflexion is but little more than an exaggeration of the normal anteversion, the menses are regular and painless, and no indication of metritis exists, the probability of impregnation may be asserted. All signs fail in a certain proportion of cases in both extremes, as well as in intermediate forms. In a class by itself, however, lies the uterus which is congenitally anteflexed and presents signs of arrested development. It is probable that the infantile form of such a uterus plays an important part in the sterility which accompanies congenital anteflexion. To this condition the term "puerile anteflexion" might be appropriately applied. The prognosis in such a case is necessarily unfavorable; for, whereas appropriate treatment might rectify mechanical obstruction or control inflammatory processes, there are no therapeutic measures which can overcome an incomplete development, or lend to the infantile uterus the anatomical and physiological qualities of the fully-developed organ.

MEDICINE.

Mosquitoes and Malaria in New England.—In a summer's observations in New Hampshire and Maine by E. O. JORDAN (Trans. Chicago Pathological Society, Nov. 11, 1901), *Anopheles* larvæ were never found in large numbers except in unshaded waters and in meadows bordering small streams. Malaria has never been known to originate in these regions. The filter-basin waters, however, which intercept the ground water on its way to the rivers, and which supply many New England towns, are rich in nitrates and algæ, and are especially favorable to the development of *Anopheles*. Accumulations of surface water do not furnish proper pabulum for this malaria-breeder, but the organism finds abundant food at the bases of water-sheds where the ground water comes into contact with light and air. Malaria, therefore, prevails along river bottoms and sea-coasts.

Technic of Widal Test.—One of the inconveniences experienced in the technic of the Widal test is the length of time necessary to obtain a suitable culture. The bouillon or agar culture of the typhoid bacillus used has required eighteen to twenty-four hours' incubation, dating from the time that the transplant was made. C. W. DODGE (Jour. Applied Microscopy, Dec., 1901) has devised a method by which this time may be materially shortened. The essential point in the method is that the culture should be started in warm broth. This is accomplished by heating the culture, immediately after transplantation, in the flame of a Bunsen burner until the test-tube feels comfortably warm to the hand. A tumbler is heated still hotter than this. The test-tube containing the culture is then placed within the tumbler and thus incubated from six to eight hours. At the end of this time it is ready for use. It is well at intervals during the incubation to remove the tube from the incubator and lightly tap it with the finger. In this manner the denser growth at the bottom is thoroughly mixed with the upper portion of the broth.

Differential Leucocyte-Count in Hydatid Cysts of the liver.—Hitherto the diagnosis of hydatid cysts of the liver has presented considerable difficulty. Exploratory puncture has been necessary in many cases. This procedure is not wholly desirable as frequently serious consequences have resulted therefrom. DARGEIN and TRIBONDEAU (Comptes Soc. Biol., Nov. 22, 1901) report observations with respect to the leucocyte-count in this condition. A hyperleucocytosis is present often amounting to 15,000 or 16,000. There is a marked increase in the number of eosinophiles. These elements often constitute 12 per cent. of the total number of leucocytes. The polynuclearneutrophilics are diminished in number, constituting from 60 to 65 per cent. of the total leucocyte-count. These blood appearances associated with enlargement of the liver are characteristic of hydatid cyst of this organ and by their means abscess and malignant growth can be easily excluded. It is thought that this method of diagnosis should be uniformly used to the exclusion of puncture.

An Undiagnosed Heart Lesion.—A girl, aged thirteen years in November, 1900, presented the following physical signs: Bulging of the precordium, a heaving, forcible cardiac impulse, a diastolic thrill at the second left interspace one inch from the sternum, great increase of cardiac dulness to the left and upward, and a diastolic, loud, rough murmur over the site of the thrill and transmitted to the left only, with a very loud pulmonary second sound. The diagnosis suggested were aortic regurgitation, congenital stenosis of pulmonary artery, and mediastinopericarditis. G. G. CAMPBELL (Montreal Medical Journal, Nov., 1901) records an examination made on August 22, 1901, two weeks before death, as follows: No cyanosis, heart slow, beats forcible, precordium prominent, impulse heaving, the fourth interspace rising, the third and fifth falling with each systole. Well-marked diastolic shock and thrill over first and second left interspace. Absolute dulness extends to second rib above, to half an inch to right of sternum, and five and a quarter inches to the left at the level of the fourth rib. At apex both sounds are clear, though the diastolic murmur is transmitted from the base. The pulmonary second sound is extremely loud, followed by a loud, rough, systolic murmur which can be heard all over the upper part of the front of the thorax. The lungs are clear. The autopsy showed large heart, weight 300 grams, normal valves, auricles slightly dilated, right ventricle greatly dilated and hypertrophied, left ventricle smaller, so that on casual observation the left ventricle would be called the right. The right ventricle shows intense mural *sclerotic endocarditis*, many of the columnæ corneæ being completely fibrosed, Coronaries small but healthy looking. No apparent lesion of lungs or pulmonary artery to account for signs at pulmonary area.

Intraspinous Injection in Tetanus.—The various methods for introducing tetanus antitoxin into the system having yielded only fair results, N. D'ANCONA (Gaz. d. Osped. e. d. Clin., Nov. 24, 1901) has sought a method which would be at once efficacious, safe, and rapid in its effect upon the nervous system. Intraspinous injection has, in his experience, met these requirements. The details and results of treatment in two successful cases are given; a description of one

suffices for both. After administration of chloroform, lumbar puncture was practised by means of a Roux syringe, 10 c.c. of the serum being injected. The immediate effect was an increase in the frequency and intensity of the spasms, but after a few hours there was noticeable improvement. Four injections of 10 c.c. each were given, with an interval of two or three days between each administration. After the second, fever subsided, convulsions occurred but rarely, and only a slight muscular rigidity was noticed. The third and fourth injections were followed by even more marked improvement, so that, by the ninth day all symptoms of the disease had disappeared, and convalescence was fully established. Noticeable features in both cases were the initial increase in the severity of symptoms after the first injection, with rapid subsidence a few hours later, and the early cessation of fever. The wound was excised in both cases.

Antipneumococcus Serum.—In testing the value of antipneumococcus serum in the treatment of pneumonia G. G. SEARS (Boston Med. and Surg. Jour., Dec. 19, 1901) endeavored to select cases in which treatment seemed likely to modify the outcome; all in whom death seemed a necessary consequence, as well as those whose youth and good habits made recovery probable, were excluded. In addition to the serum treatment other methods were applied, as cold sponge for temperature, oxygen, alcohol and other stimulants where they seemed necessary. Four patients out of twelve died, showing no apparent change in the mortality-rate. The duration of the disease in the cases receiving the serum treatment was about the same as in any series of cases not so treated. An extension of the process after the use of the serum was noticed in three cases. No appreciable influence on the fever could be discovered.

Newer Methods for Determining Renal Insufficiency.—It has been questioned whether cryoscopy and the employment of methylene blue and of phloridzin represent any real advance in the clinical diagnosis of renal insufficiency. J. KISS (Berlin klin. Woch., Dec. 2, 1901) has carefully analyzed these methods and is not enthusiastic over their value. In the first place the physiological limits of the reaction to phloridzin injections are not fully established. Apparently normal reactions are at times obtained, as in cases cited by the author in urines which contain considerable albumin. Where pathological processes are present in the neighborhood of the kidney the latter may secrete a diminished number of molecules in solution. A temporary diminution of renal function may be reflex and may not signify at all a loss in functional power. In regard to methylene blue and its elimination as a test of renal sufficiency, it is necessary to remember that cases of uremia have been reported in which the methylene blue test failed to show any disturbance of renal function; while, on the other hand, apparent departures from normal elimination of methylene blue often are noticed where the kidneys are known to be normal. The author is not willing to accept cryoscopy as a functional test *par excellence;* the latter may fail to disclose any abnormality in cases presenting cylinders and other pathological urinary elements. A marked lowering of the freezing-point of urine is known to occur in other conditions than disease of the kidneys; for example, in cyanosis, diabetes and acetonemia. Diabetes and acetonemia, however, can be excluded by chemical tests; and Korányi maintains that the freezing-point can be restored to normal in cyanosis by the use of oxygen.

Chronic Recurrent Fever.—In the year 1887 the cases which were at that time known under the general title of Hodgkin's disease were divided by Ebstein into two classes, namely, those accompanied by recurrent fever and those without it. The former set of cases, which Ebstein believed to constitute a diseases *sui generis*—"chronic recurrent fever"—has been made the subject of a special study by H. BATTY SHAW (Edinburgh Med. Jour., Dec., 1901). The disease is essentially identical in its symptoms with the regular type of Hodgkin's, and, indeed, ordinarily presents simply a later development of that condition. The characteristic point of difference is the occurrence of a periodical recurrent fever of a very special type. The febrile attack takes place about once in each month, the periods of pyrexia and of apyrexia lasting about two weeks each. These attacks are accompanied by certain general and local symptoms. There is almost always increase in size of the enlarged glands and of the spleen, which subsequently shrink, only to again increase with the next attack. In some cases the enlargement of the glands is associated with a marked intensification of the redness, pain, and heat of the overlying skin; in the same manner the enlargement of the spleen may find subjective expression in pain on the left side. In some of the cases, there is great constitutional disturbance with rise of temperature, rigors, vomiting, diarrhea, anorexia, and malaise, and in about 30 per cent. urobilinuria is a marked symptom. These very remarkable attacks begin to make their appearance on the average seven and a half months before the fatal outcome of the disease, although they may occur as much as fourteen months before death. What is the status of these cases with recurrent fever? Are they only peculiar forms of lymphadenoma, or are they to be classed entirely by themselves? The fact that so many cases of Hodgkin's run their course for months and years without showing a trace of recurrent fever, and, still more, the fact that cases with this fever are simply continuations of cases previously typical, would seem to argue for the superposition of some new factor upon those concerned in the production of a typical Hodgkin's. Ebstein referred the fever to infection by some unknown bacterial agent. This suggestion has found rich amplification in more recent bacteriological research, since in 1896 at least twenty-nine of such cases examined for micro-organisms had shown positive results. The findings have not, however, been uniform, inasmuch as bacilli, micrococci, streptococci, and typhoid-like forms have severally been identified, either in the blood or in the tissues of the various cases examined. Other etiological factors have been suggested as agents in the production of the fever, such, for example, as the periodical absorption of toxin or the successive formation of metastatic deposits, but they are all of an indefinite and unsatisfactory nature. Dr. Shaw concludes, therefore, that the periodic fever is due to a secondary and terminal infection of variable character, and that it represents nothing but an accidental variation of Hodgkin's disease. Chronic recurrent fever, as a disease, has no status. From the standpoint of diagnosis, the recognition of the condition is of some importance in connection with cases of typhoid fever with relapses, and with general miliary tuberculosis, the fever of which may in some cases mimic its type.

Thoracentesis.—Notwithstanding the voluminous literature upon the subject, the value of thoracentesis in cases of pleural effusion continues to be one of the moot questions of medicine. There is hardly a medical procedure of equal importance, upon which clinical experiences and clinical teachings are so much at variance. L. BARD (Revue Med. de la Suisse Romande, Nov. 20, 1901) has succeeded in throwing an

entirely new light upon the problem, both in its theoretical and in its purely practical aspects. He holds that thoracocentesis is *a priori* a logical procedure, inasmuch as it is essentially an artificial and a rapid path to the *restitutio ad integrum*. The very serious accidents and the not infrequent failures which have attended its use are faults not inherent in the method itself, but attributable entirely to the improper estimation of the amount of fluid to be withdrawn. If too much be taken there is danger of edema of the lung, displacement of the viscera, and even of a reinauguration of the effusion; if too little, the expected benefits do not accure to the patient. Yet the practitioner is at present without a guide in steering his course between these evils, unless, indeed, he is willing to put his trust in the "average figures" which have been suggested, or in the purely subjective sensations of his patient. Prof. Bard has devised a new instrument by means of which he proposes to determine physiologically the amount to be withdrawn in each case. The principle is that of the manometer, just as in Baginsky's instrument for evacuating the meningeal fluid by lumbar puncture. The original trocar and cannula of Potain is used, and to it a graduated glass tube, one meter long, is attached by means of a short piece of rubber-tubing. The instrument having been introduced and the trocar withdrawn, it is evident that the fluid will rise in the glass tube to a level which varies according to the degree of intrapleural pressure. In the average case the fluid fluctuates betwen +2 or +3 centimeters during inspiration to +8 or +10 in expiration; the lowest range of figures in Bard's series of cases was from —3 to +4 during the respiratory act, the maximal +10 to +17. It is an interesting observation that the level of the fluid as registered in the tubes is always considerably below that indicated by the physical examination. Bard found that he obtained the most favorable clinical results, including the progressive absorption of the fluid, by arresting the puncture when the oscillations just failed to reach the level of the puncture, that is, at a point corresponding to a level of —1 during inspiration, of —5 in expiration. These figures he considers to represent the true pressure values of the intrapleural space in health. If the claims made in this article are well-founded, the method represents a permanent and very important addition to medical practice. At all events, the simplicity and practicability of the procedure should win for it a widespread and thorough trial.

PATHOLOGY AND BACTERIOLOGY.

Etiology of Hay-Fever.—During the past few years the pollen-theory of hay-fever has attracted considerable attention and many adherents have been added thereto. In this connection the recent work of B. HEYMAN and T. MATZUSCHITA (Z'tschrift f. Hygiene u. Inf., Nov. 22, 1901) is of interest. They first inquired into the quantity of pollen particles in the air during the season of the year when hay-fever is prevalent. They found that only a very small number of such particles are present in the air: in the average 25 to each cubic meter. The bacteriological examination of these particles shows that they contain only a very small number of micro-organisms. Only from one to five organisms are present in the entire pollen from one blossom. They next examined the nasal and throat secretions of healthy persons, hay-fever patients, and individuals suffering from various other nasal affections. The hay-fever patients showed less pollen in such secretions than any of the other persons examined. With respect to the micro-organisms present, they found that staphylococci predominated in the nares of persons suffering from other nasal affections, while in hay-fever patients streptococci were most abundant. They conclude that the pollen-theory of hay-fever is untenable. They are undecided as to the bacterial excitement and the mode of its transmission.

Agglutination of Tubercle Bacilli.—The clinical value of the agglutinating property of the blood-serum of tuberculous patients in the early diagnosis of the disease has been much disputed. The fact that the bacilli grew in small clumps resembling an agglutination proved a great hindrance, and although a method had been devised which obviated this, it was so difficult in execution and uncertain in its results that it never came into general use. A simple procedure and the results from its employment have been contributed to the literature of the subject by ROBERT KOCH (Deut. med. Woch., Nov. 28, 1901). The method of securing the test-culture is briefly as follows: The pure culture of the B. tuberculosis is removed by filter from its fluid culture-medium. It is dried and a weighed quantity rubbed up in an agate mortar with weak 1 to 50 normal caustic soda solution in the proportion of 1 to 100. The liquid is then placed in a centrifuge and when separated from its sediment is further diluted with normal salt solution and a ½ per cent. carbolic solution, until the proportions of culture and diluent are about 1 to 3,000. A dried culture which can be more accurately weighed has also been used. The serum is secured from the blood of the patient by centrifugal action and is diluted nine times with a mixture containing a 5 per cent. carbolic solution and 20 per cent. glycerin only when it is desired to preserve the same for some days. For testing the agglutinating properties of any given serum, a definite quantity is diluted with the test-fluid in proportions varying from 1 to 10, to 1 to 100. These mixtures are placed in the incubator from fifteen to twenty hours, and the reaction as shown by the various degrees of cloudiness noted. In experiments on animals the agglutinating properties varied, being least marked in rabbits and goats, more so in horses. What value this may have in deciding the amount of resistance to tuberculous invasion in these species, has not as yet been determined. In observations made on immunized animals (injected with pure cultures of tubercle bacilli) it was found that goats were most responsive, the agglutinating power of the serum was quickly raised to 1 to 50 and in some cases to 1 to 1000. This property seemed to be most marked in seven to ten days after injection and then gradually declined. The author believes that there is a well-marked relation between the agglutinating power and the degree of immunization, and that the former can be taken as a gauge for the amount of the latter. In observations on the human subject, however, but little difference could be found in the serum of those free from or those afflicted with tuberculosis, so that the value of this phenomena as a diagnostic factor was abandoned. Nevertheless, as it appeared rather simple to increase the resisting powers of the animal with the greater value of the agglutinating property, the author believed that the procedure might prove an important factor in rendering a patient immune. He injected subcutaneously very weak dilutions of the pure culture in increasing doses every day or two, until a reaction, with rise of temperature of one and a half or two degrees, took place. The intervals were then lengthened to six or eight days and the agglutinating power observed. The injections are kept up and if possible given stronger and at greater intervals for as long as a year if possible. It was found that the early stages of phthisis were most fa-

vorably affected by the development of these antitoxins which seemed to correspond with the appearance of an increase in the agglutinating powers. Such patients showed a general improvement, appetite better, night-sweats disappeared, also the râles and the sputum diminished, and temperature gradually returned to normal. The presence of the bacilli in the sputum seemed a good guide in determining the length of the treatment. Koch believes that his method is of service in the diagnosis of tuberculosis, if supplemented by other methods or in cases where these have failed.

Ascaris Causing Puerperal Fever.—A case is reported by D. W. PRENTISS, JR. (Amer. Jour. of Obstetrics, Dec., 1901) in which the temperature rose to 102.4° F. on the second day, and continued irregularly and intermittently for nine days. There were tenderness and pains in the upper abdomen, but no chills, no leucocytosis, no malaria found in blood. The fever was uninfluenced by quinine in large doses. Cultures from the uterine cavity showed no pyogenic germs. On the ninth day of the fever a large worm, *Ascaris lumbricoids*, was passed by rectum, and the next day the fever, pain and tenderness disappeared and did not return.

Tuberculous Infection Through Milk.—The question of tuberculous infection by ingestion of milk is answered in the negative by N. ASPE (Rev. d. Med. y Cir. Prac., Nov. 21, 1901). If the tubercle bacillus reaches the cow's udder, it must necessarily be carried thither by the blood. The bacillus has yet to be found in the blood; but, supposing its presence there, we are taught to believe that every gland in the body, by its selective power, takes from the blood only those elements which are necessary to the elaboration of its peculiar products. This would seem to dispose of the possibility of infection of the milk before it leaves the cow's body, unless the elective faculty, attributed to other glands be denied to the mammary. Granting this possibility, if we recall that in the production of experimental infections by subcutaneous inoculation, the first organs to be affected are the lymphatics, it is natural to suppose that the first and invariable effect of the ingestion of tuberculous milk would be the development of tabes mesenterica, yet primary tabes is comparatively rare. The author of this paper further raises the question of identity between the human and bovine tubercle bacillus, and quotes experiments in inoculation of cows with cultures from human tuberculous products with negative results in the nineteen animals experimented upon, whereas, animals injected with the bovine form quickly succumbed, and autopsy showed tuberculous lesions.

Bacteriuria in Zymotic Disease.—The bacteriological analysis of the urine in disease is of great importance not only from a diagnostic, but also from a hygienic and therapeutic standpoint. C. J. LEWIS (Edinburgh Med. Jour., Dec., 1901) has written an article which challenges attention upon each one of these grounds. He studied the urine in cases of typhoid, scarlet fever, and diphtheria, examining the filtrate of a large number of specimens. In typhoid, he examined the urine of 45 cases, all of which had given a positive Widal, examining 158 specimens in all. The bacillus of Eberth was identified only once, but in a large number of cases the B. coli, or a coliform bacillus was found. The ratio of true typhoid bacilluria would thus be about 2 to 3 per cent. of the cases, which contrasts markedly with the ratio of 25 per cent. as determined by several other investigators. In view of the fact that the typhoid organism occurs in the blood itself of only about one-fourth of the cases, the latter figures would seem *a priori* to be exaggerated. A fruitful source of error is the confusion with other similar micro-organisms, notably the B. coli, and the forms described as B. typhosus simulans A., B., C., and D. Of the specimens examined, 33 per cent. revealed albumin. Of scarlet fever, 16 cases were studied, 51 specimens being examined. Two forms of streptococcus were obtained from the urine, neither form corresponded to the S. scarlatinæ of Klein. Of diphtheria, 17 cases were examined, in 14 of which the B. diphtheriæ was present in the throat. In none of the 43 specimens studied was the specific organism to be found. Albuminuria was present in five cases. The author believes that the healthy kidney is not capable of eliminating living bacteria, although it is able to remove the toxins resulting from their activity. Bacteriuria is only possible when there is a disturbance of the integrity of the renal epithelium, and is therefore, as a rule, associated with albuminuria, pyuria, or hemoglobinuria. The latter conditions should furnish a valuable indication regarding the possible admixture of the bacteria. All wines containing bacteria should, he believes, be disinfected by means of carbolic, formalin, or sublimate.

Pathogenesis of Cephalhematoma.—Among the endocranial affections of infants may be mentioned the rare condition of bony cyst due to extravasation of blood between the cranial bones and the periosteum, says G. PACINOTTI (Gaz. d. Osped. e. d. Clin., Nov. 24, 1901). In the majority of cases such an extravasation, if moderate in amount, is quickly absorbed; but where traumatic injury to the cranial parietes causes a sudden and violent exudation of blood between parts which neither yield to pressure nor admit of infiltration, the blood may remain *in situ*, causing irritation of the tissues with production of an encapsulating connective-tissue membrane and surrounding bony ring. This latter is a reactive production of abnormal ossification, from which may eventually arise a capsule of bone, the hematoma thus being converted into a true bony cyst. Instead of organizing, as might be expected, the blood-clot undergoes fatty and granular degeneration, so that in place of the coagulum a cavity arises, filled with a serous fluid and surrounded by a lamella of connective tissue rich in blood-vessels and pigmented by detritus of the blood. Study of the case of an infant at whose birth a tumor was noticed and supposed to be an ordinary scalp tumor, but which developed into a bony cyst, causing the child's death in convulsions at the age of two months, leads Pacinotti to question the possibility of such a cyst being formed from a cephalhematoma arising at birth. The anatomical changes which a cephalhematoma must undergo in its development to a bony cyst with serous contents hardly seem possible of accomplishment in the short period of sixty days; therefore it seems probable that some injury to the mother's abdomen or possibly circulatory lesions in the fetus due to changes in the position of the head *in utero* to extravasation of blood between the osseous trabeculæ of the parietal bone in the formative period some time prior to birth. The conclusions of the author are that cephalhematoma in the new-born is not always due to conditions of parturition, but may be caused by some injury to the bony trabeculæ of the parieties in its period of ossification in intra-uterine life, leading to extravasation of blood. To this form he would apply the term trabecular cephalhematoma.

Etiology of Typhoid Fever.—It is well known that milk and water are the most frequent channels through which typhoid infection is transmitted. From time to time cases of this disease have been observed

which have apparently owed their existence to other sources. SCHÜDER (Z'tschrift f. Hygiene u. Inf., Nov. 22, 1901) has studied the literature of 650 cases of typhoid fever from the standpoint of the source of infection. These cases were distributed throughout various countries and occurred at all seasons of the year. He finds that 20 per cent. owe their origin to an infected water supply. In 17 per cent. the milk supply was the source of infection. Various other varieties of food were the carriers of the bacilli in 3.5 per cent. of the cases. In the vast majority of instances water becomes contaminated by the feces and urine of typhoid patients. The control of the spread of the disease, therefore, largely resolves itself to the problem of the prompt and thorough disinfection of these excretions. The absence of an early diagnosis is one of the most potent factors in the spread of typhoid fever. In a fair proportion of cases the diagnosis is not made and means of disinfection instituted until valuable time has been lost, so far as the prevention of other cases is concerned.

THERAPEUTIC HINTS.

Acute Bronchitis.—A diaphoretic, diuretic and relaxant for use at the outset is:

℞ Potassi citrat..... 24.0 (℥vi)
Liq. ammon. acet.....150.0 (℥v)
Spt. ætheris nitrosi..... 30.0 (℥i)
Vini ipecac ..... 8.0 (℥ij)
Syr. pruni virg. q.s. ad.....240.0(℥viij)

M. Sig: Fifteen c.c. (℥ss.) in water every two hours until the secretions are loosened. When this is not productive of free secretion, and troublesome cough continues, use:

℞ Ammon. muriat..... 20.0 (℥v)
Codeinæ .....2.5-3.5 (gr. iv-vi)
Spt. junip. comp..... 15.0 (℥ss.)
Mist. glycyrrhiz. comp.... 75.0 (℥iiss.)
Syr. pruni virg. ad..... 120.0 (℥iv.)

M. Sig: Four c.c. (℥i) every two hours.—J. M. ANDERS.

Tuberculosis.—For the cough, night-sweats, etc., R. COUETOUX (Bull. général de therapeutique, Nov. 15, 1901) vaporizes a tablespoonful of the following in the bedroom every night:

℞ Creosote ..... 20.0 (℥v)
Eucalyptol ..... 4.0 (℥)
Alcohol .....150.0 (℥v)

When this has become unpleasant to the patient, or if the cough is dry and expectoration difficult, he uses two or three tablespoonfuls of

℞ Acidi lactici..... 20.0 (℥v)
Acidi acetici ..... 20.0 (℥ijss)
Acidi benzoici..... 10.0(℥iiss)
Alcohol .....150.0 (℥v)

By alternation this fumigation may be continued indefinitely.

Care during Pregnancy.—The clothing must be loose, corsets, circular garters and belts omitted, and the weight of the skirts borne by the shoulders. The underwear should be of wool. Fresh red meat is to be taken only once daily. Avoid veal, pork, hashes, stews, rich gravies and fancy dishes. Live on plain, digestible food, with some fruit. Milk, coffee, tea, light wines and beer may be consumed, according to previous habit. The teeth need special care. It is well to avoid extraction of a tooth if possible, and only temporary fillings should be employed, as decay is more likely to occur in pregnancy. Warm baths are beneficial, best just before retiring. Vaginal douches to be used only when ordered. Russian, Turkish or surf-bathing to be avoided. Exercise in the open air to the point of slight fatigue is good, but sewing-machine, dancing, and active exercise must not be attempted. Railroad travel in comfortable cars can ordinarily be permitted from the third to the eighth month, but it is best not to travel during the few days corresponding to a menstrual period. Owing to the increased demand on her oxygen supply, the pregnant woman should avoid close or crowded halls, churches, etc. There should be a regular hour for retiring, not later than ten o'clock, and the evenings should be spent quietly to promote restful nights. The patient should remain in bed for an hour after breakfast till the tendency to nausea disappears. After the noon meal, an hour should be spent lying down. The breasts should be warmly covered and free from compression; the nipples washed daily and for the last two months bathed with Cologne water and rubbed with cocoa butter. Constipation must be avoided if possible.—W. S. BOWEN in American Journal of Obstetrics, Dec., 1901.

Suprarenal Extract in Cardiac Cases.—The active principle of this gland is neither proteid, carbohydrate, nor fat. It is soluble in water, dilute alcohol and acids, but insoluble in pure alcohol, ether or chloroform. Removal of both glands is followed by extreme muscular weakness, loss of vascular tone, loss of appetite, general prostration, and death in from twelve to seventy-two hours. Intravenous injection of the watery extract is a powerful tonic. W. E. DEEKS records a case of mitral insufficiency, myocarditis and arteriosclerosis, and a case of probably malignant endocarditis, in which all other heart tonics had failed, and in which prompt relief from the failure of compensation followed three-grain doses of suprarenal extract three times a day. He used it also with good effect in two cases of Graves' disease. There was no gastric disturbance even when the stomach was hypersensitive.

Gastric Stasis with Hypersecretion.—The syndrome of Reichmann is often met with in gastric pathology. The patients have a good appetite, sometimes even being tormented by hunger; but they often dare not eat for fear of intense pain which comes on toward the end of stomach digestion. The pains are relieved temporarily by food, drink or alkalies. Stomach peristalsis may be visible. The victims become thin, weak, nervous and irritable. A test-meal shows a large amount of fluid of excessive acidity, with much free hydrochloric acid. The treatment for this condition which has been most successful in the hands of A. MATHIEU and A. LABOULAIS (Bull. général de therapeutique, Nov. 8, 1901) is evacuation of the stomach-contents, without lavage, followed by the injection, through the tube, of powdered meat. The stomach is emptied as much as possible, preferably before a meal, a little water being used if the mucus is very thick. Then, by gavage, 60 grains (℥ij) of powdered meat are administered, mixed with 300 c.c. (℥x) of milk. This amount is increased slowly till 100 grams (℥iijss) of meat and 400 c.c. (℥xiij) of milk are given daily. The rest of the diet must be arranged according to the symptoms. Intense pains with considerable stasis require milk diet; when pain is less marked, eggs may be given, and soft foods such as gruel. Severe cases may require lavage about twice a week. Temporary relief must be obtained from sodium bicarbonate or magnesia in large doses when the pain begins. The almost immediate cessation of the pains, the diminution in the quantity of the liquid of stagnation, and the improvement in the patient's condition are remarkable. The meat powder acts by taking up the excess of hydrochloric acid, and by its nourishing powers and completely dissolves so as to leave nothing solid to cause pyloric spasm.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

SMITH ELY JELLIFFE, A.M., M.D., Ph.D., Editor,
No. 111 FIFTH AVENUE, NEW YORK.

Subscription Price, including postage in U. S. and Canada

SATURDAY, DECEMBER 28, 1901.

A PROPER HONORARIUM.

IN considering an appropriate reward for the medical attendants upon the late President McKinley, an occasion has arisen for the Government of the United States to openly confer upon the profession of this country a sign of appreciation. Other governments have their academies, where honors are bestowed upon the great, or their monarchs who courteously acknowledge by medals, titles and appointments their indebtedness to men of science. But the United States has no formal means of expressing to the practitioner of medicine the Nation's appreciation of signal service, apart from those in the army or navy corps.

The medical profession of other nations, as well as that of our own country, is waiting with interest to see if Congress will do the graceful and proper thing by the physicians who attended the late President McKinley. Their services were rendered not to a private individual, but to the head of the nation, and represent the earnest and conscientious effort of science to save to the people the man who had received the assassin's blow because he was the Nation's chief.

A suitable pecuniary award by Congress would not be the mere discharge of an official duty, but would be an opportunity for the people of this country to express through their representatives their indebtedness to the science of medicine and to its practitioners.

Such an expression, we believe, has never been made in the form of a public gift to physicians. Generous men have founded hospitals and endowed medical colleges; scientists have bequeathed medical libraries, but these are as means of relief to the sick. No adequate expression has ever been made to the men themselves, who gratuitously give their services in the hospitals and whose brains work out for their patients the requisite knowledge in the libraries; and yet there are few citizens of the Republic who do not feel that they owe more to some physician than they can ever pay. What shall a man give in exchange for his life? Surely he will add a little gratitude to the few dollars that represent the doctor's value of his care.

As a nation the people of the United States now have an opportunity to acknowledge their indebtedness to the medical profession by conferring a munificent honorarium upon those who were in attendance at Buffalo. The cordiality with which Congress pays this tribute to the late President's physicians will mark in history the value which the people of the United States set upon the medical skill of their land at the beginning of the twentieth century.

GERMAN MEDICAL HUMOR.

HUMOR confined to certain lines is apt to degenerate after a time. Perhaps this is true even of so good a thing as the annual joke number of the *Münchener medicinische Wochenschrift,* which has just come to hand. It may only be, however, that previous excellent issues of the "Scherznummer," which, according to the announcement on its title-page, is gotten out without any assistance on the part of its distinguished staff of collaborators, have led us to expect too much from our German medical humorist colleagues. The present number certainly contains an amount of very amusing material that will serve, as far as anything ever can in this benighted world, to enable us to see ourselves as others see us. Some of the articles deserve extended quotation. We can cite only some of the very best things.

The article by Professor Dr. Quaatsch on "The Descent of Man" is a good take-off on the usual style of anthropological paper read at medical congresses. The author considers that Darwin has outlived himself, especially since his death!

The Darwinian theory of man's descent must be fundamentally reformed. The hypothesis that all men belong in the category of the vertebrate animals is completely without foundation, since it is a notorious fact that most men have no backbone at all. Many of them belong to families of the mollusks—they are lobsters or clams. A large number of them (much more than is usually thought) belong to the class of insects. Besides, the difference in the character of the backbone of various individuals makes it incredible that all should be classed among the same kind of vertebrates. In some the backbone has never become quite ossified.

One of the best things in the number is the article on "Human Life as a Circular Insanity." It begins with a sly hit at Kraepelin's recent declaration that practically all of the mental disturbances are sure to recur. Some of the reasons why human life must be considered as a typical example of circular insanity are worth quoting. For instance, there can be no doubt that human existence begins with congenital imbecility, the first symptom of which is a decided tendency to echolalia. Pa-pa, ma-ma, ta-ta constitute the entire speech faculty, and these syllables are heard only after they have been repeated by some one else. The next prominent symptom is a decided tendency to coprolalia, which finds its outlet in such characteristic expressions as pe-pe, ah-h, h, h. About the age of six the period of "that tired feeling" begins. This symptom is entirely subjective and, since the promulgation of the latest hygienic school regulations in Germany forbidding school-hours for children in the afternoon, it is felt only in the morning and is never noticed on Sundays. In a word, there is a psychopathic periodicity about this affection which is noticeable even at a very early time of life.

Certain stuporous symptoms are apt to be distinctly prominent a little later in life, especially about the time of examinations. Difficulties in reckoning, especially about the time that reckonings have to be paid, are not seldom in this, the adolescent period of life. At times there are distinct lacunæ in the memory as regards certain hours, especially of the night. In the course of certain lucid intervals, or remissions of the usual circulatory insanity, a man may come to amount to something. Inevitably after this, however, there sets in a condition of euphoria, *i. e.*, of internal self-content, which can not but be considered as a psychopathic symptom of the beginning of degeneration.

There is a good take-off on the gynecologists, their detailed interest in the slightest changes in the position of uterus and adnexa, and their invention of multiform and multiplex instruments for the correction of presumed deformities, in an article on the position of the testicles. This is written by Dr. Fritz, a specialist for andrology, as he calls himself, who has invented a number of instruments with the aid of which operations can be performed that will secure the fixation of both testicles exactly in the same plane, horizontal and vertical, and set them, besides, exactly in the same angular position.

The Germans are apt to be freer than American and English medical men with regard to sexual hints in their jokes. The present "Scherznummer" has perhaps a little bit more of this fault than preceding copies of the Muenchener "Joker." The poetic description of a corneal corpuscle as the servant-maid of the eye, with two yielding anterior processes and a large staphyloma posticum, is a quaint bit of humor that scarcely crosses the line in this latter regard. Other things are not so quotable. As usual, even the advertisements are jokes. The firm of Salber & Quack announce a number of opo-preparations. One of the testimonials runs as follows: "Since early youth I have been childless and unmarried. Now, thanks to the use of your opo-preparations, I have become in a very short time several times a papa, for which receive my thanks."

A TALE OF CANCER AND CORKS.

THE study of the etiology of cancer has occupied pathologists ever since the dawn of scientific medicine, but never was there a time when the search for the true cause of malignant growths was more eagerly pursued than during the past few years. It is not astonishing, therefore, that every announcement of a new discovery, purporting to be the solution of the problem of the cause of cancer—and there have been many such discoveries of late—is greeted with acclamation by the readers of the yellow and yellowish journals, both here and abroad, in which such news usually appears with flaming headlines and exaggerated or misstated facts.

None of these "discoveries" has been hailed more enthusiastically by the lay public and probably none received with more mental reservation by the initiated than that of Professor Max Schüller of the University of Berlin, who recently gave to the world the results of his researches in this field in a monograph entitled

"Die Parasiten im Krebs und Sarcom des Menschen." In this work he says that when cancerous tissue was excised aseptically and placed in tubes which were sealed and kept at body temperature for a few days, the contents of the tube became semiliquid, and near the edge of the liquid there appeared a number of small, grayish-white points which proved to be colonies of the new parasite. He knew that these parasites were the specific germs of cancer because when the cultures were injected into rabbits, they produced tumors which he recognized as cancerous growths.

Hauser, of Erlangen, recently had the courage to examine most minutely the work of the author of "Die Parasiten im Krebs und Sarcom des Menschen," and to go so far as to examine the very specimens which Schüller used as a basis for his claims. To his astonishment he found that the parasite described by Schüller bore so close a resemblance to the ordinary "stone cells" of cork that he was led to say: 'Any one can scrape all the parasites of cancer he desires from any ordinary cork." Moreover, Hauser found that in most cases the "parasites" were not embedded in the tissues in the sections examined, but were simply strewn or sprinkled thereon. Finally, he found that the alleged cancerous tumors produced in rabbits by inoculation of Schüller cultures were not cancerous at all, but simply masses of granulation tissue. Further comment is needless to show that there are students of pseudoscience in other lands than this.

ECHOES AND NEWS.

NEW YORK.

Lying-In Hospital Work.—There were 50,228 births in the borough of Manhattan during the year ending September 30, 1901, and more than 5 per cent. of these were under the care of the Society of the Lying-In Hospital, at Seventeenth Street and Second Avenue, as is shown in an annual report just issued. This is an increase of one per cent. over the service of last year, and the report further states that the new hospital, the gift of J. P. Morgan, which is now but partly finished, will be wholly ready for occupancy within a few months. The report says that there has been no increase in the accommodation provided by the Department of Charities: 60 beds for waiting women and 56 beds for women in childbirth, 50 beds being located on Blackwell's Island in the Metropolitan and City Hospitals, and 6 beds in the Emergency Hospital in Twenty-sixth Street. The number of applicants cared for by the society has been 3,757, an increase of 739. Of these the society visited and relieved 2,723 (561 more than the total of the corresponding period a year ago). Out of this total there were only ten deaths. Of those treated, 263 were natives of this country and 2,444 foreign born. One thousand six hundred and thirteen of this number emigrated from Russia, 444 from Austria, 99 from Roumania, and the balance from other countries. Out of 3,309 applicants, 2,854 lived in front rooms and the remainder in rear tnements. Of 2,910 cases the husbands were without employment in 1,006 instances. In 2,268 cases the number of living children was 5,738. Of the 50,228 births in Manhattan, 24,917 were reported by physicians and 25,311 by midwives. Last year the service of physicians and midwives was about equally divided. The report says that some attempt has been made to regulate the practice of midwives by requiring them to pass an examination as to their ability; but a bill to that effect introduced in the Legislature failed to become a law, and at present a license can be obtained by any woman merely by presenting a certificate of competency, signed by two medical men. The report calls attention to the fact that the signs "midwife" in French and German, so common on the East Side, in most instances are exhibited by women whose only experience has been gained either by having borne a child themselves, or by having acted as nurse for neighbors and friends. If they are ignorant, they may carry infection from one house to another, and even in the simplest cases bring fever and death to their patients. When it is considered, says the report, that more than 25,000 women in this borough in the past year received obstetrical treatment from midwives, the necessity of solving this important question becomes urgent to those who are endeavoring to improve the condition of neglected mothers.

Metropolitan Medical Society.—At the last meeting of the Metropolitan Medical Society the following officers were elected for the ensuing year: President, Dr. W. M. Leszynsky; Vice-President, Dr. F. L. Wachenheim; Recording Secretary, Dr. W. M. Brickner; Corresponding Secretary, Dr. S. Yankauer; Treasurer, Dr. I. Pierce Oberndorfer.

Portrait of Rudolph Virchow.—Through the courtesy of Messrs. Schering and Glatz the profession of this city are in receipt of a very excellent portrait of Dr. Virchow.

Department of Charities Appointments.—Commissioner Keller of the Department of Public Charities published last week a list of appointments of hospital attendants, pupil nurses, etc., and an equally long list of dismissals, resignations, and "dropped-from-rolls" of the same class of help. The changes net the Commissioner about $1,500 saved.

Vaccination of Buffalo University Students.—Students of the University of Buffalo were duped December 20th, and later every one has a sore arm as a result of being vaccinated. The various classes were directed to meet Dr. Charles G. Stockton, a member of the faculty, at a stated hour. It was rumored that Dr. William Osler, of Johns Hopkins University would deliver an address, and all the students assembled to hear it. When all were together the doors were closed and the students were told to bare their arms for vaccination. Every student in the university was vaccinated.

A Reform in the New York Prisons.—The doing away with the cutting of the hair of convicts is a gratifying proof, says the Evening Post, that those in charge of this State's prisons are open to the arguments of progressive penologists. To the average citizen such a change may seem of the slightest significance, or, if anything, only the disuse of a time-honored measure of discipline. It is, however, as striking an action as the abolition of the lock-step last spring, and both arise from the desire to make each prison a reformatory, and not an institution for branding men who have made missteps. The hair-cutting process was a relic of sev-

enteenth or eighteenth century prison methods, when actual branding of prisoners was also the vogue. Its abolition will make it easier for convicts to obtain employment on discharge, as well as help them to retain their self-respect during their confinement. The aim of the modern prison is to correct by discipline, to strengthen physically, to train intellectually, and to awaken morally. Hair-cutting, the lock-step, and striped suits are all hindrances, and not helps, in this undertaking.

Stony Wolde Sanatorium.—Lots Nos. 265, 295, 296, 307 and 308 of Township Ten, of the old military tract in Franklin County, have been purchased by the Stony Wolde Sanatorium as a site for its institution. The project for the establishment of this sanatorium is one in which many well known society people in New York are interested, and has for its object the furnishing of a temporary home for dependent young women who are threatened with pulmonary diseases.

Study of Morphine.—Dr. J. B. Mattison, Medical Director, Brooklyn Home for Narcotic Inebriates, offers a prize of $400 for the best paper on the subject: Does the Habitual Subdermic Use of Morphine Cause Organic Disease? If so, what? Contest to be open two years from December 1, 1901, to any physician, in any language. Award to be determined by a Committee: Dr. T. D. Crothers, Hartford, Conn., editor Journal of Inebriety, Chairman; Dr. J. M. Van Cott, Professor of Pathology, Long Island College Hospital, Brooklyn, and Dr. Wharton Sinkler, Neurologist to the State Asylum for the Chronic Insane, Philadelphia. All papers to be in the hands of the Chairman, by or before December 1, 1903: to become the property of the American Association for the Study and Cure of Inebriety, and to be published in such journals as the Committee may select.

Medico-Legal Society.—The annual meeting of the Psychological Section was held in joint session with the annual meeting of the Medico-Legal Society on December 18, 1901.

Medical Reconciliation in New York.—The suggestion of Dr. Frank Van Fleet, President of the Medical Society of the County of New York, that committees from the two county medical organizations meet and confer with reference to a union of the two organizations, was very cordially received by the New York County Medical Association, and in response thereto the following preamble and resolutions were unanimously adopted at the stated meeting of the Association on December 16th:

"*Whereas* the following resolution has been received from the Medical Society of the County of New York,

"*Resolved*, That the President of the Medical Society of the County of New York appoint a committtee of five, of which he shall be chairman, provided a similar committee be named by the New York County Medical Association, to confer with that body wth reference to a union of the two organizations; and that this committee be requested to report to the Society at the stated meeting in January, 1902, or sooner, in order that this society may, if desirable, make a recommendation to the Medical Society of the State of New York at its next annual meeting; and

"*Whereas* the subject of union of the medical profession in this State, as expressed in the foregoing resolution as presented by the Medical Society of the County of New York, is wholly a State question; and

"*Whereas* the published charter and by-laws of the New York State Medical Association do not allow its county associations to act independently on State questions:

"*Be it Resolved*, That we heartily favor a union of the profession in one State medical body, and respectfully suggest that the Medical Society of the County of New York request the Medical Society of the State of New York to appoint a committee to consider this question; and

"*Be it further Resolved*, That the New York County Medical Association request the New York State Medical Association to appoint a committee of conference in case the Medical Society of the State of New York shall appoint a similar committee."

PHILADELPHIA.

Dr. Coley Addresses Medical Students.—Dr. William B. Coley of New York visited this city December 17th as the guest of Dr. Hobart A. Hare and the H. A. Hare Medical Society of Jefferson College at their annual banquet. Preceding the banquet Dr. Coley addressed the students of Jefferson in the college amphitheater, speaking of various medical and surgical topics. He stated that the proper relation between medicine and surgery had not yet been reached, many operations that are not needed being performed. Surgery, both general and special, is open to the accusation of overstepping its bounds. An accurate knowledge of the after-history of patients is of very great importance as a guide in future cases. Other topics discussed were medical etiquette, immunity and serumtherapy, and the origin of cancer.

Care of the City's Poor Consumptives.—Dr. John V. Shoemaker has outlined the plans for the extensive sanitarium which is to be erected on the Philadelphia Hospital grounds for the care of the 500 consumptives in the almshouse. Eight pavilions are to be constructed, the frames to be of steel and the roofs and sides of glass. Ample facilities for ventilation will be afforded and in each pavilion will be placed electrical appliances furnishing static electricity for the generation of ozone. By this means it is believed that the air of higher altitudes may be sucessfully simulated. The patients will be classified and assigned to the pavilions according to their condition. By the means just mentioned isolation can be practically secured.

Initial Symptoms of Smallpox.—In a paper read at the recent meeting of the North Branch of the County Medical Society Dr. Jay F. Schamberg gave the results of a study of 100 cases of smallpox recently admitted to the Municipal Hospital. The cases included confluent, profuse rashes, moderate eruptions, and mild varioloid. The most common symptoms of the disease were present in the following proportions: Headache, 86 per cent.; chills, 78 per cent.; backache, 70 per cent.; vertigo, 57 per cent.; vomiting, 55 per cent.; nausea without vomiting in 10 per cent. In only 2 cases was there complete absence of initial illness. Attention was called to the fact that in a large percentage of the cases admitted to the hospital during the past year the family physicians had interpreted the initial symptoms as the early manifestations of typhoid fever. Dr. William M. Welch stated that of the 800 patients admitted to the hospital during the present outbreak of the disease not one had been recently vaccinated.

Magnitude of the New Water System.—The new filtered water system which Philadelphia is installing at a cost of $15,000,000 has been declared by Consulting Engineer Hill to be "the greatest municipal improvement in the history of the world, and to which is comparable only, though lesser in magnitude, the renovation of the entire sewerage system of London thirty years ago." The principal feature, in addition to the large number of filter beds previously mentioned, is the conduit which is to convey the water

from the filter beds at Towesdale to Lardner's Point Pumping Stations where it will be forced into the distributing reservoir. The conduit will be 14,000 feet in length and will be cut out of sold rock, this making it necessary to place the conduit 100 feet below the surface of the earth. When finished it will have an inside diameter of 10½ feet and a carrying capacity of 360,000,000 gallons per day.

Smallpox Decreases Despite Cold Weather.—The health report for the week ending Decembr 21st shows 76 new cases of smallpox and 10 deaths, compared with 125 cases the preceding week.

Street Cars Still Unheated.—The campaign for heated street cars has again opened and the prospects for success are about as bright as usual. Suburbanites are especially bitter in their complaints, the cars being in the majority of instances without the semblance of heat. A party of Germantown people recently made a round trip in one of the cars sitting around an oil stove which they placed in the aisle as an object lesson to the company. The only result was the suspension for two days of the conductor who allowed the stove to remain in the car.

An Amusing Tirade Against Vaccination.—An article in a local paper by Julian Hawthorne would excite only amusement were it not that the prominence of the writer is apt to work havoc with the credulity of certain people. A few of his sentences are quoted: "I hold, with an odious and incorrigible minority, that the present fad of vaccination for smallpox is not only disgusting but vain. The fact is, as everyone who knows anything at all about the matter knows, that no doctor knows except empirically (which is not knowledge) why or how or even if vaccine injections perform the function that is claimed for them. We are fighting the disease-devil, not with the angel of health, but with a disease-devil of the same family only smaller. Let us not forget that smallpox itself is now seldom fatal; with anything like a fair chance, any doctor who deserves his diploma can cure it." The medical fallacies of the article are equaled only by the English employed.

CHICAGO.

Dunning Plans Changed.—Plans for using the consumptive hospital at Dunning for insane patients have been abandoned. Instead, all patients at the Dunning institutions in the first stages of consumption will be removed to the hospital, which will fill it, it is believed. The amusement building will be converted into a ward for insane women, and the patients who have been required to sleep on the floor will be accommodated there. A storage-room in the poorhouse will be fitted for the use of insane men. At a recent meeting of the County Board Advisory Committee, a committee consisting of Dr. Frank Billings, Dr. Hugh T. Patrick, and President Hanberg, was appointed to devise means for a permanent reorganization of the administration, medical and nursing departments.

Hospital Sued.—William P. Shephard has brought suit in the Superior Court for $50,000 damages against the Chicago Hospital. It is claimed that Mrs. Shephard was severely burned by the explosion of a gasoline stove early in October. She was taken to the Chicago Hospital, where she lingered nearly a month and died. It is said by the physicians of the Hospital that no treatment could have saved the woman's life.

The Smoke Nuisance.—In the ordinance prepared by Health-Commissioner Reynolds and introduced into the City Council recently, the public at last has something like a rational and practicable plan for suppressing the smoke nuisance. The ordinance proposes to abate the evil by attacking its cause. Instead of trying to check the nuisance at the top of the chimney, it proposes to stop it where it originates—in faultily constructed furnaces. Under this plan the smoke inspector and the boiler inspector will work in combination, and their joint efforts will be directed toward compelling property owners to construct their furnace rooms and boiler plants on proper models. Where a defective plant is already in operation, the bureau thus created will be empowered to take steps to compel the necessary changes. With furnaces and boilers of the right design and use, the responsibility for a smoky chimney will be plainly chargeable to sloth, neglect or incompetency. There will be no longer an opportunity for violators of the smoke ordinance to claim that they are trying to obey the law, but find it impossible to do so. A proper enforcement of such an ordinance as is now proposed promises better results than any other plan which thus far has been presented.

Indications and Limitations of Massage of the Prostate Gland.—Dr. Louis E. Schmidt read a paper on this subject before the Chicago Medical Society, in which he said it was necessary to understand what was meant by massage of the prostate. It could best be shown when the kind of cases were considered where it was adaptable. First, there were cases in which the physician intended to treat inflammatory infarctions or congestions. Massage was applied in order to hasten their absorption by stimulating the circulation. Second, there were cases in which the physician wanted to express the fluid contents, especially out of pathological cavities. Third, cases in which it was necessary to produce normal development of the undeveloped prostatic sphincter muscle. Fourth, cases of impotence, which were due to loss of the prostatic function, in patients in whom infection had not taken place, but in whom exhaustion had set in following excesses. Massage was indicated in all those inflammatory diseases of the prostate gland in which the enhancing of the absorption was at issue, or in cases in which the prompt and regular removal of accumulated secretion was desirable. Furthermore, it was indicated in cases of insufficient development of the prostate and prostatic sphincter in youthful individuals, and also in certain cases of sexual exhaustion.

Diagnosis of Latent Frontal Sinusitis.—Dr. George E. Shambaugh read a paper with this title, in which he said that inflammatory tissue of the frontal sinus might be either manifest or latent. The manifest inflammations were not common and were readily recognized by the physician. Latent inflammation was much more common, but often very difficult to diagnose. Latent frontal sinusitis often lasted many years, with scarcely a single symptom which would lead one to suspect its presence, except at times when an acute exacerbation lighted up the process and caused symptoms which were temporarily more or less marked. Such symptoms were frontal headache and tenderness on percussion or pressure over the sinus. These symptoms were often absent in frontal sinusitis, and when present might be due to causes outside of the sinus. Transillumination was not so reliable as with the maxillary antrum. In cases of long standing, secondary degenerative changes were often found in the mucous membrane about the middle meatus, such as mucous polyps, polypoid degeneration of the anterior end of the middle turbinated body, and degeneration of the tuberculum septi and the unciform process. These changes might be caused by suppuration of the antrum or of the anterior ethmoid cells. A continuous discharge of pus into the middle meatus was often given as characteristic of frontal sinusitis, but this symptom might be caused by suppuration of the anterior eth-

moid cells, and frontal, or infundibular cells drained directly into the infundibulum. Discharge from the frontal sinus was often intermittent when the naso-frontal duct was partially closed or when the discharge was slight. By the presence or absence of part or all of the above symptoms, we could neither diagnose nor exclude frontal sinus disease. The diagnosis must be made by the actual demonstration of pus in the frontal sinus. The typical outlet for the frontal sinus was through the naso-frontal duct into the anterior end of the infundibulum, then through the hiatus semilunaris into the middle meatus. The atypical passage was direct from the sinus into the middle meatus, in front and to the median side of the hiatus semilunaris. In cases where the middle meatus was obstructed by polyps or by the middle turbinated body, the first step was to open the meatus freely by removing the polyps, and the anterior end of the turbinated body. With this accomplished, there were three methods of diagnosing pus in the frontal sinus. First, the introduction of a catheter and irrigation of the sinus; second, diagnosis by exclusion; third, making an exploratory opening into the sinus. To catheterize the sinus, a soft silver catheter was bent about one inch from the tip at a right angle upward. One should try to pass it through the typical passage. If this failed he should try through the atypical passage. Obstructions met with were deviations of the septum, mucous polyps, the middle turbinated body, a narrow infundibulum and frontal cells which opened into the infundibulum. To determine whether the catheter had entered the frontal sinus, or whether it had lodged in the infundibulum or an ethmoid cell, the X-ray gave the most satisfactory results. In cases where the catheter could not be introduced, the diagnosis by exclusion might be tried. First, the maxillary antrum should be eliminated by washing out this sinus. Then one should note whether pus reappeared in the middle meatus, and whether it came from the opening to the anterior ethmoid cells or from the ostium frontalis. When this method failed, as a last resort, an exploratory opening should be made into the sinus. This could best be done from without at a point just under the inner end of the eyebrow, where the slight scar would not be seen.

GENERAL.

Study of Foods.—Many people eat much more than is necessary. Professor Atwater of Wesleyan University told a recent gathering of physicians in Hartford, according to the Post. Especially do we use an excess of sugar, starch, and fat in our foods. The opinion of many physicians that, taking the country at large, the injury that comes from wrong dietary habits is, on the whole, greater than that from the excessive use of alcohol, finds a good deal of support, Professor Atwater said, in the dietary inquiries being made under the direction of the United States Department of Agriculture. They emphasize, also, the need of more skilful cooking, and the Professor regards the movement toward the teaching of such subjects in our public schools as one of the hopeful signs of the times. Another general fact illustrated by the inquiries is that people understand very little about the relation between the nutritive value of food and its cost, and that the poor are especially apt to be extravagant in their purchase and use of food.

To Study Leprosy.—It is reported that Jonathan Hutchinson is to go to South Africa to study leprosy. He is to go to Robben Island and thence to Natal and Basutoland.

Havana's Sanitary Condition.—The report of Major W. C. Gorgas, Chief Sanitary Officer at Havana, to Governor-General Wood for the month of November, says that the sanitary condition of Havana continues excellent. The death-rate was 19.58 per thousand. This compares favorably with cities of the same size in the leading civilized countries of the world. The report adds: "During the month we have had no cases and no deaths from yellow fever. This can be said of no preceding November since 1762. Taking this month for the last eleven years, the maximum number of deaths from this disease occurred in 1896, when we had 244; the minimum in 1898, when we had 13; average, 48. Last year, 1900, we had, during this month, 213 cases and 54 deaths. This year the last case of yellow fever occurred on September 28; that is, we have gone over two months without a single case or death belonging to Havana. I consider this a demonstration that Havana has at last been freed from the infection of yellow fever. It must be remembered that October and November are the months when yellow fever is rife in Havana, and that, for the past century, there has never been a day during these two months when there were not many cases of yellow fever in the city; and very few years can be picked out, in all this time, in which the record for each day during these months does not show several deaths. This result I consider due to the system, introduced last February, of killing infected mosquitoes in the neighborhood of each point of infection as it developed."

Study of Cancer in Germany.—Dr. Wutzdorff of the Geman Imperial Health Department has lately made extensive researches which show that there has been a decided increase in recent years in Germany, as in other European countries, in the prevalence of cancer.

Experiments in Tuberculosis.—The Royal Commission on Tuberculosis has accepted two farms in Essex offered by Sir James Blyth for experimental purposes. Experiments that will last two or three years will be made in bovine and other kinds of tuberculosis.

CORRESPONDENCE.

OUR LONDON LETTER.

(From Our Special Correspondent.)

LONDON, December 14, 1901.

ELECTION OF DIRECT REPRESENTATIVES TO THE GENERAL MEDICAL COUNCIL—EXCESS OF OPERATIVE ZEAL IN DISEASES OF THE UPPER AIR-PASSAGES—THE NOSE AS THE CENTER OF THE PATHOLOGICAL AXIS OF THE HUMAN MICROCOSM—BREATHING EXERCISES AS A CURE FOR ADENOID VEGETATIONS IN THE PHARYNX—A NEW SPECIALTY—A NEW JOURNAL—THE TWO PARTIES IN BRITISH GYNECOLOGY.

THE election of direct representatives of the profession in England and Wales to the General Medical Council ended this week in the return of two men so utterly unknown to fame that it is useless to mention their names. But little more than a third of the profession took the trouble to record their votes, though the voting is done by post-card; and of those who did the majority, as is apparent from the result, belong to the lower intellectual strata of the profession. The men they have sent to the Council are fit representatives of their constituency, and on this ground the choice of the electors may perhaps be justified. But it must make the judicious grieve to see the figure cut by direct representatives whose speech is like that of illiterate tradesmen in a body mainly composed of highly educated gentlemen. I have already told you that the bulk of the profession cared nothing about the

election, but I confess I was not prepared for such a preponderance of abstention. The most significant feature in the election is the intervention of Mr. Victor Horsley, who not having any contest of his own on his hands, threw himself into the fray as the champion of a candidate who, though in himself nothing more than a respectable provincial mediocrity, was by comparison with his competitors a shining ensample of all legislative virtues. On his behalf Mr. Victor Horsley put forth all his undoubted powers as a stump orator. He addressed meetings in various parts of the country, and wrote reams of "rattling and indignant eloquence." He "laid on" with the savagery of Macduff; he was profuse, as is his controversial method, in opprobrious epithets and reckless charges; misused not the King's press, but the medical press, and also the King's English damnably (the expression is Falstaff's and is therefore permissible in polite society); and the end of it all is that his *protégé* has been thoroughly well beaten. If he stands again, he will have a better chance if he can induce Mr. Horsley to take the opposite side or at any rate not to encumber him with help. If he knew Latin, he might say *Non tali auxilio nec defensoribus istis!* The most important result of the election is that Mr. Horsley's influence—which not long ago was preponderant for the simple reason that no other direct representative for England had any scientific standing—has received a serious blow. He is threatened with the fate of all demagogues when they do not push blindly on fast enough to please the rabble at their heels. Already he is being denounced as too conservative; it will be interesting to see what the issue of the contest will be next year when he will have to offer himself for reëlection.

Some excitement has lately been caused among the specialists who take the nose, the ear and the throat as their province by a vigorous onslaught made by Sir Felix Semon on certain excesses of operative zeal which he declares to be too common among them. These gentlemen have since been engaged in fitting the cap on their own or each other's head. Sir Felix Semon is particularly hard on the rhinologists who are apt to look upon the part to the care of which they devote themselves as the center of the human microcosm. Oliver Wendell Holmes somewhere says that there is no little town whose inhabitants do not seem that the axis of the earth sticks out visibly through its market-place. I could name more than one specialist here who seems to look upon the nose as the visible end of our pathological axis. Any trifling deviation of the septum, or bony spur projecting from its surface, or swelling of the turbinate bodies, is treated as the cause of any constitutional or local disturbance that the patient may be suffering from. There may seem to be even less connection between the conditions than there is between Monmouth and Macedonia, but an explanation is easily found in "reflex neurosis." Hence, the nose must be attacked *vi et armis* and cleared of everything that offends the surgical artist's sense of symmetry. If there be no manifestations at all, yet possible foci of incalculable mischief are there and must be removed. How far this scientific fanaticism may go is shown by an incident which occurred at the Laryngological Society not long ago. A case of périchondritis of the larynx was exhibited and puzzled all the pundits present. Some thought the disease was malignant, others syphilitic, others tuberculous; in short, no satisfactory solution was forthcoming. Then a specialist, who, as Malebranche saw everything in God, sees everything in the nose, solemnly called the attention of the learned doctors to a tiny spur on the patient's septum; in that, he said, lay the secret of the laryngeal disease. This oracular utterance was received with a roar of laughter. The serious part of the business is that enthusiasts of this kind carry their fixed idea into practice, and ravage the nose with snares, spokeshaves and cauteries; they radically cure whatever defects and diseases it may have by leaving no structure for disease to lay hold of. *Solitudinem faciunt, pacem appellant.*

The same is the case with regard to adenoid vegetations. The tiniest excrescence in the vault of the pharynx may cause more woes to the patient than the wrath of Achilles brought on the Greeks; therefore it must be excised or destroyed. Some time ago the operation was so fashionable that in many households all the denizens of the nursery were, as it were, passed at the edge of the curette. Fashionable operators reaped a rich harvest; a lady was heard to say that it had cost her $1,250 to have her children's chimneys swept. At the present time a reaction has set in and as usual the pendulum has swung too far the other way. This is in large measure due to the fact that a surgeon of considerable eminence two or three years ago made the remarkable discovery that operative procedures were quite unnecessary, and that "systematic ventilation of the lungs and nasopharynx provided us with a means not only of applying to the nasopharynx such force as is exerted by air being forcibly drawn through it, but by oxygenating the blood more fully and removing more thoroughly the carbonic acid, etc." These objects were to be accomplished by putting the child on its back three times a day for half an hour at a time and making it breathe in and out as deeply as possible through the nose, the mouth being kept shut. Parents were naturally delighted to adopt a method so simple and so inexpensive. Unfortunately, though temporary swelling from local congestion may be reduced, real adenoids are not in practice conjured away by "breathing exercises." It is not easy to understand how they could; the idea savors more of magic than of medicine. Nor has the inventor of the method vouchsafed any explanation of the process by which hypertrophied lymphoid tissue is got rid of by breathing exercises; challenged on the subject, he lies low like B'rer Rabbit and "says nuffin." On the whole one could more readily believe that it could be blown out by a vigorous use of the pocket handkerchief. The position, then, is that for the moment breathing exercises have to a considerable extent taken the place of operation for the removal of adenoids, and a new specialty has grown up which is already a highly profitable source of revenue to those who practise it. One clever lady professor of "health exercises" is said to make $35,000 a year by the application of the method to adenoids alone. Naturally the operative specialists regard this as a revolting form of quackery.

Sir Felix Semon's philippics against overoperating are generally approved of except by those against whom they are directed. It was high time that some one spoke out, for there is unquestionably a vast amount of unnecessary operating not only among those who may be conveniently termed respiratory specialists, but among abdominal surgeons and others. Some of the rhinologists charge $250 or even $500 for the removal of a spur of the enlarged end of a turbinated bone. But it is not all mere lust of gain. At one special hospital it is said that some years ago lower turbinals had to be swept up with a broom on operation days; at another the story runs that a distinguished American visitor who had incautiously placed his hat on the table found it half full of tonsils when he tried to put it on. Such are the results of misdirected enthusiasm. But when enthusiasm takes

the form of frightening private patients into needless operations by lurid pictures of inflammation spreading through the cribriform plate of the ethmoid to the base of the brain; of hopeless deafness likely to be caused by the spread of a simple catarrhal process from the nose to the ear; of ever-imminent danger of cerebral abscess from the presence of a small exostosis in the auditory meatus, we reach a misty mid-region in which enthusiasm at least merges into if it does not become simple charlatanism.

The *Journal of Obstetrics and Gynecology of the British Empire* is the somewhat clumsy title of a new monthly periodical which is to appear in January. We already have the *British Gynecological Journal,* which, if it cannot be said to flourish, at any rate continues to exist. It is the organ of the British Gynecological Society, which has never been looked upon with favor by the leading men of the specialty. One of the causes of this is that among its founders and most active spirits was Lawson Tait, who was too strong a man not to have many enemies, and, it must be added, too Napoleonic in his handling of statistics and other small matters of detail to be altogether approved of by martinets of professional propriety. The new journal starts under the highest auspices. Among its promoters are Sir John Williams, Dr. Champneys, Dr. Herman, Professor Morduch Cameron of Glasgow, Professor A. R. Simpson of Edinburgh, and other prominent obstetricians and gynecologists throughout the kingdom.

The editor-in-chief will be Mr. Alban Doran, formerly assistant to Sir Spencer Wells. He is the author of a successful "Handbook of Gynecological Operations" and assisted Sir James Paget in compiling the great catalogue of pathological specimens in the Museum of the College of Surgeons. The Committee in the terms of their prospectus "aim at making the journal an impartial and complete record of British work, an exponent of British obstetrical and gynecological practice, and an encyclopædia of contemporary thought and achievement in obstetrics and gynecology throughout the world." If the editor is to please his employers he will find some difficulty in making his record of British work either impartial or complete; one could name off hand half a dozen laborers in the vineyard of gynecology, able men, and, like Hamlet, indifferent honest, whose work will be treated as the man who fell among thieves was treated by the Levite.

The gynecological fraternity here is split up in two separate and, as regards the leaders of each, definitely antagonistic sections. They are represented respectively by the Obstetrical Society of London and the British Gynecological Society. These two are nearly equal in numbers, for the simple reason that they are both to a large extent made up of the same men who belong to the category of the *fortisque Gyas fortisque Cloanthus,* who followed Æneas. But the light and leading are almost wholly in the Obstetrical Society. There was a very pretty trial of strength between the two factions a year or two ago when it was proposed that the International Congress of Obstetrics and Gynecology should be held in London. The "British Gynecological" faction made a bold effort to capture the Congress, but the opposition of the "Obstetrical" party brought the scheme to grief, and the Congress had to look elsewhere for a place of meeting. The new journal is another move by the "Obstetrical" for the further discomfiture of the "British Gynecological" party.

That is the true inwardness of its foundation, though no mention of it appears in the prospectus.

TRANSACTIONS OF FOREIGN SOCIETIES.

French.

DIAGNOSTIC VALUE OF JACKSONIAN EPILEPSY—MALARIA WITH LYMPHADENOMA OF THE LIVER AND KIDNEYS—FUNCTIONAL DISTURBANCES OF THE HEART AND DEFORMITY OF THE CHEST—OVARIAN DYSTROPHY—BILIARY PLEURISY—ENLARGEMENT OF THE LIVER AND PHOSPHATES IN THE URINE—BACILLUS OF DYSENTERY—ANTITYPHOID ANTITOXIN.

THE following French societies have held meetings during the past month. The most important papers presented are these:

LABORDE, at the Academy of Medicine, November 19th, outlined a certain number of facts, experimental and clinical, which tend to prove that, if excitation of the zone of Rolando is the most frequent cause of paralysis and convulsions in the extremities, it is not by any means the only one, thus stimulation of the convolutions in front of or behind this zone may equally well provoke the same symptoms. It follows, therefore, from the practical point of view, that in looking for a lesion which produces a paralysis or convulsion, it is necessary not only to inspect the zone of Rolando, but also the convolutions in front of and behind it.

DIEULAFOY, in defense of his original paper on this subject, stated that not only do lesions in this area of the brain cause Jacksonian epilepsy, but also those in the frontal convolutions. He, therefore, concludes that if this new conception of this type of epilepsy is true, it causes no offense to the doctrines of localization within the brain, especially that which names the zone of Rolando as the point of departure for motor impulses to the extremities. This idea has already passed many phases and has finally come to be less and less exclusive in such a way as to enable one to reconcile certain observations which differ from this diagnosis in its absolute form.

LE GENDRE, at the Medical Society of the Hospital, November 15th, gave a history of a man, twenty-seven years old, previously afflicted with malaria and presenting all the signs of obstruction of the aorta. In this patient after admission to the hospital a tender enlargement of the liver was found with a hard, uneven nodular surface. At the same time he had fever, profuse sweats and other severe symptoms and finally died. At the autopsy there were found two strictures of the aorta situated respectively just beyond the sigmoid valves and just before the origin of the brachiocephalic artery. The liver and the kidneys were the seats of multiple lyphadenomata. Fernet stated that he, too, had seen several patients with chronic malaria with which there appeared in various organs of the body lymphomata or lymphadenomata. It seems possible, therefore, that there is a relation between malaria and the development of these tumors.

LAMY discussed functional affections of the heart with extracardial murmurs due to th deformiy of the chest in connection with the case of a man, twenty years of age, who, at the least effort suffered from oppression, palpitation and other cardiac symptoms. A number of physicians had diagnosed his case as one of organic disease of the heart, because the apex-beat was four finger-breadths beyond the nipple and the precordial region was the seat of a loud systolic murmur. Careful examination showed that in reality the cardiac dulness was normal and that the murmur was extra- and not intracardial. The apex of the heart appeared to be depressed simply because the chest was greatly deformed, being very narrow and flat. It is possible that the unfavorable position of the heart within the chest accounted for all the functional trou-

bles of the patient, undoubtedly, however, unduly rapid growth also had a great deal to do with them.

DALCHÉ described the symptoms of a patient who suffered from ovarian dystrophy at the same time presenting many of the symptoms of Basedow's disease and pseudomyxedema, namely, tachycardia, flashes of heat, attacks of sweating, etc. Later there appeared also many of the signs of myxedema, namely, infiltration of the skin, dyspepsia and bloating. It seems, therefore, that the proper treatment for such an ovarian condition should be considered with the other two diseases and their symptoms.

GILBERT and LEREBAULLET, at the Society of Biology, November 9th and 16th, said that they had seen three cases which proved the possibility of complications in the pleura during the course of benign or severe biliary infection. The observations were respectively a simple catarrhal jaundice, severe jaundice secondary to violent attacks of hepatic colic and an angiocholitis following subacutely upon suppuration. These three cases show that pleurisy can be the result of a perforation through the diaphragm by a suppuration through the liver and of a catarrhal angiocholecystitis or gall-stones without damage to the diaphragm. It seems to be due in certain cases to germs of infection in the biliary passages. It can also be caused by general infection of the liver without having much to do with the former. In the second of their two cases a tuberculous pleurisy was stirred up after having become quiescent by a hepatic colic which followed an injury. In general the pathogenesis of these biliary pleurisies may be compared to the same disease after appendicitis, as shown by Dieulafoy. Like that their severity follows that of the original source of infection. Their situation is always on the right side and undoubtedly results through a propagation not by the circulation, but more directly by the lymphatics. The infective material passes through the lymphatic channels and glands of the diaphragm without any perforation whatever of this and then excites pleurisy and pericarditis. A good example of this is found in the complications of pyoperihepatitis. It seems proven, therefore, that this is the true explanation of such complications late in infection of the liver both acute and chronic. Lépine, as long ago as 1882, proved that large livers in man may contain a very large amount of lecithine and that in the same patient and at the same time the urine may show a large quantity of incompletely-oxidized phosphorus or of phosphoglyceric acid. This may be present in many times its normal proportions, usually in the same ratio as the urea. Thus, it is not only in certain nervous conditions as have been lately observed that phosphorus incompletely oxidized is present in the urine, but also in certain individuals this abundance is a definite sign of enlargement of the liver. All of his recent researches have tended to affirm these statements.

MOREUL and RIEUX addressed to this same society notes describing a new organism which they have found alone and associated with other germs in all cases of dysentery. In such cases the other germs are much less active and numerous. This new bacillus ferments lactose without the formation of indol. The serum of animals into which the germ has been injected acquires active powers of agglutination for the bacillus of Eberth, but not for the colon bacillus. Finally, the serum of the immunized animals is antitoxic toward the poison of dysentery, but does not seem to possess any such action toward the bacilli of Eberth and Escherich.

CHANTEMESSE, at the Medical Society of the Hospitals, November 8th, read a paper on the serum-therapy of typhoid fever. From the typhoid toxin he has been able to develop an antityphoid serum with properties not only preventive, but also antitoxic and anti-infectious. The curative value of this serum is realized when one considers the fact that typhoid fever in the various hospitals of Paris shows a death-rate of 29 per cent. in adults and 10 per cent. in children. The mortality of this disease in general appears to have been 18.5 per cent. in Paris during 1899 and 1900. He has treated 100 cases with the serum, 29 in his own service at the Bastien Hospital and the others in the services of other men. All of those inoculated before the tenth day were cured. Of the others, six died; three of perforation of the intestine, one of general peritonitis, two because they were inoculated too late (twenty-first and twenty-fifth days of the disease) in the presence of hyperthermia and a pulse of 140, the sixth of a gangrenous disease of the sacrum; two other patients, who received the serum while they were in a hopeless condition, were also lost. The temperature charts show as a rule a rapid decline of the fever and of the pulse-rate. The injection should be made even in young and vigorous subjects, victims of the disease, severe in type, but without complications. If the serum is given on the eighth day or later, one may even see signs which promise a cure, but these do not continue, the infection returns to its former activity, and then a second injection is necessary which does not stop the malady suddenly but gradually. Moreover, this limit of eight days is not absolute. It depends upon the activity of the infection as related to the strength of the individual. Therefore we see typhoids which are not at all severe checked by an intervention on the eighth, ninth and twelfth days. Occasionally there are relapses after the injection, the patient has not conquered the infection even with its help. Under this treatment the duration of typhoid fever is notably decreased, generally continued improvement, the diarrhea is decreased or stopped in three or four days, the fever falls and the pulse and circulatory excitement returns to nearly normal state. The blood-pressure is so much improved that the injection of saline solution and of the caffeine would be very dangerous. The secretion of urine is more active up to three or four quarts a day. The serum has never been known to produce albuminuria, it even causes slight degrees of this condition to disappear. Finally, the injection of serum produces a manifest hyperleucocytosis with the return of eosinophile cells. Sometimes a rise in temperature is produced by the serum, moderate in degree, short in duration and followed by a temperature which is below that of the disease previous to the injection. This occurs in light cases. In severe cases such reaction may be violent and prolonged, requiring frequent cold baths to conquer. Complications in patients treated with the serum are rare. In his one hundred cases, only three had perforations of the intestines, one pneumonia, two intestinal hemorrhage, one otitis, and two saphenous phlebitis. Of these only the first four died. The injections themselves are not painful nor irritating, are best made in the skin of the forearm, and are rapidly absorbed, more so from this point that anywhere over the abdomen. In his one hundred cases after the injection two showed slight erythema, although the patient received twenty-five or thirty cubic centimeters; the usual dose at the first injection is twelve or fourteen cubic centimeters. If at the end of five or six days the fever has not decreased another injection of four or five cubic centimeters should be given; in a mild case, ten cubic centimeters; more in a severe case. The first dose may be ten cubic centimeters if the injection is given at the outset of

the disease; if it is given later a larger dose must be used at first. In addition to the serum two other means of treatment are necessary for success, cold baths which support the patient and decrease the temperature, and as much fluid food as can be borne.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE—SECTION ON ORTHOPEDIC SURGERY.

Stated Meeting, Held November 15, 1901.

George R. Elliott, M.D., Chairman.

Orthopedic Operations for Intractable Cerebro-spinal Lesions.—Dr. Homer Gibney read this paper and reported two cases recently operated on in which marked improvement in locomotion was noticed. The two cases reported were Friedreich's ataxia. The in-co-ordination of the lower extremities was in a measure overcome by tenotomies and fasciotomy for correction of the existing pes cavus and trigger toe. He insisted on first correcting the deformity and then, with properly-adjusted apparatus worn for a long time, claimed marked benefit and in many cases complete removal of the interference incident to the paralyses.

Dr. Henry Ling Taylor said he agreed with Dr. Gibney in regard to the great value of operative procedures in properly-selected cases of paralytic deformity, particularly in children. While it was true that operations designed to remove deformity or restore stability to a helpless limb not infrequenly resulted in disappointment, owing to imperfect mechanical treatment afterward, it was no less true that mechanical treatment was often imperfect or unduly prolonged by the failure to grasp the indications for operating.

Dr. John McG. Woodbury said he could not discuss the paper, as he came late and did not hear it, but expressed the opinion that chiefly operative procedures held out the possibility of recovery or permanent improvement; non-operative measures alone were simply palliative.

Dr. George R. Elliott said the field referred to was a large one and many a cripple was bedridden or going about with contractures and post-paralytic deformities that could and ought to be relieved. He cited as an example a patient upon whom he had recently operated who had been bedridden for three years, owing to post-typhoidal contractures of spinal origin. By proper tenotomies, manipulation, and subsequent use of apparatus, the girl was now walking quite as well as ever.

The Effect of Osteitis of the Knee on the Growth of the Limb.—Dr. Henry Ling Taylor read a paper with this title and said that from measurements of the femoræ, tibiæ, feet and patella, during or after osteitis of the knee, in forty cases where the disease had begun in childhood, the following conclusions were reached: (1) The affected limb, if approximately straight, was longer in the first four years in the large majority of cases. In observed cases of adolescents and adults it was from one to several inches shorter, when the disease had lasted over seven years. (2) The affected femur was nearly always longer in the first four years, and the lengthening of the limb mainly due to lengthening of the femur. In the older cases, after a duration of seven years or more, the femur was markedly shortened. (3) The tibiæ were usually equal in length in the early stages; later the tibia of the affected side might be slightly longer for a time, but oftener shorter; the shortening increased considerably in the older cases, and after the subsidence of inflammation. (4) With limbs of equal length and a duration of several years, the femur of the affected side was found longer and the tibia shorter than its mate. (5) The foot and patella showed a difference in favor of the sound side after one year and frequently before. (6) The stimulation of growth in the affected femur was accompanied by a retardation in the tibia, foot and other parts; growth in the femur itself was finally retarded. The result after many years was often considerable shortening of the limb.

Dr. T. Halsted Myers said that his observations were almost identical with those given by the reader of the paper. In fifteen cases observed by him the lengthening was generally in the femur, and in some cases the femur lengthened while the tibia shortened, in others both bones were lengthened. This occurred during the active stages of the disease, but he could not speak positively as to the ultimate result. He thought it probable that, if the knee recovered with good motion, there was less shortening, and asked Dr. Taylor whether he had noticed that limbs left with stiff joints shorten more than the others. The proper functioning of the joint after the cure of the disease was a most important element in securing the best nutrition and development of the limb.

Dr. H. A. Parish stated that there was no doubt about ultimate shortening in the majority of cases. He cited, however, the case of a girl, aged sixteen years, disease of thirteen years' duration, remarkable for great lengthening during the active stage of the disease. After a partial excision ten years ago, and recently a supra-condylar osteotomy of the femur, and a cuneiform section of the tibia for the relief of flexion deformity, there existed only ⅜ of an inch shortening, with limb at angle of 175°.

Dr. V. P. Gibney said that years ago Dr. Perry had called attention to the subject of the reader's paper, and from the examination of 50 cases had found the femur had grown in length. In his own practice he had been disappointed not to find lengthening. While lengthening was generally believed to be the rule, it could be readily understood how shortening might occur from interference with the nerve supply by pressure of the head of the tibia on the popliteal space. He referred to a patient seen ten years ago who had 1½ inches lengthening after a long course of protection treatment. The girl was still young and the joint disease cured; she was allowed to use the limb freely and atrophy set in. At the same time the joint of the healthy limb was protected and after four or five years the normal femur lengthened and the diseased one shortened, so that ¼ inch difference was the final result.

Dr. Taylor, in reply to Dr. Myers' question, said that lengthening of the femur was the rule while the disease was active, and it was probable that more shortening occurred in the deformed and badly-managed cases. In the latter, the final result would usually be considerable shortening in adult life. He referred to the work of Leusden who took measurements of radiograms, and reached conclusions nearly identical with his, except that Leusden had no opportunity to study adult cases where the disease had begun in childhood.

Dr. V. P. Gibney asked Dr. Taylor how he accounted for the shortening in neglected cases. Dr. Taylor replied that he considered it due to retarded growth.

Dr. V. P. Gibney said he was at a loss to understand why the bones shortened and would be glad to look over the statistics presented by Dr. Taylor. He sup-

posed Dr. Berry's cases would be called neglected cases.

Dr. Taylor said that his statistics in the majority of instances were not made from neglected cases, though it was probable that most of the adult cases might be so called.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, Held December 9, 1901.

TheVice-President, Wm. McCollom, M.D., in the Chair.

The Suppression of Quackery.—The committee appointed to consider methods for the suppression of quackery, Dr. Ransom E. Van Gieson, Chairman, made a report setting forth the difficulties of the problem, and made the following recommendation: "That this Association address a communication to the incorporated medical societies of this city, suggesting the formation of a Conference Committee to meet with your Committee, such Conference Committee to consist of one representative for each one hundred members of the society to be represented; to meet at the earliest possible date to take this matter into consideration and to form, if possible, a permanent body."

The recommendation was unanimously adopted by the Association, after it had been so amended as to include organizations in the State as well as the city.

Nominations for Officers.—Dr. Andrew H. Smith was nominated for president, and Drs. S. Carrington Minor and Reynold W. Wilcox were renominated respectively for chairman of the Borough of the Bronx and member of the Executive Council.

Discussion on the Present Treatment of Cardiac Affections.—The discussion was opened by Dr. Thomas E. Satterthwaite. The variety and stage of a disease, he said, had to be considered in its treatment. While this proposition might be regarded as a truism in the abstract, in the concrete, that is, in actual practice, its force was not fully appreciated. In speaking of the prophylaxis of endocarditis, he stated that in his own experience he felt certain that whenever he had been able to contend effectively against the primary disease on which it depended, he had usually been successful in warding off the endocarditis. When endocarditis has supervened, if the cause happens to be lithemia, the salicylates or other rheumatic remedies are still appropriate, together with rest in a supine position, cooling applications or counterirritation, and opiates, if necessary. In acute endocarditis he would not recommend Caton's plan of giving mercurials or iodides. Until quite recently he had been skeptical as to the cure of malignant endocarditis under any circumstances; but successful cases had been reported, and the use of such intestinal antiseptics as sulpho-carbonate of sodium, inunctions of colloidal silver by the Credé method, and, possibly, injections of streptococcus serum offered hope when otherwise the prognosis was almost hopeless.

In the treatment of the first stage of valvular diseases—lasting until the establishment of compensation—an effort should be made, after the febrile period is passed, to arrest the constitutional disorder, remembering that it tends to chronic pulmonary, hepatic or renal implication. The most careful regimen and suitable hygienic conditions are here of the utmost importance. Little medication is required, but monobromate of camphor (in two-grain doses) or tincture of aconite (in two-minim doses) will prove of service when palpitation occurs, while glonoin (in $^1/_{100}$-grain doses) will usually be all sufficient in threatened heart failure. When the patient has reached the second or stationary period, and satisfactory compensation has been established, he needs no treatment, though advice is still useful. When compensation fails, however, prompt treatment is important, if life is to be saved. Venesection, hydragogues and opiates are to be carefully avoided, and the modern treatment by baths and exercises not only enables one to dispense with these, but also with those drugs that are improperly used to stimulate the heart. Exercises and carbonated baths can be successfully utilized by any physician in any part of the country, if he will faithfully follow the rules that have been reported so fully in the MEDICAL NEWS. In addition to the active and passive movements prescribed, the patient should be instructed to walk daily in the open air, but never to hurry. In fact, no form of physical strain is allowed, while mental strain is also interdicted, and attacks of acute indigestion are to be avoided with special care. As to contra-indications to the use of baths and exercises, patients with parenchymatous nephritis, arteriosclerosis, where apoplexy is threatened, and patients with diabetes, where the amount of sugar is large, are not likely to be benefited, and are not proper subjects for the treatment.

In the subacute dilatation of neurotic or anemic young people, where baths and exercises are not available, nutrients like malt, iron, quinine, and the alkaloids of nux vomica may check the dilatation and restore the heart's tone. In general, strychnine or brucine, in $^1/_{60}$- to $^1/_{30}$-grain doses are good nerve tonics, but, as they contract both heart and arterioles, are undesirable for continuous use. Lately Dr. Satterthwaite has been using the tincture of the hawthorn-berry in the fatty heart as a substitute for strychnine. The cactus or night-blooming cereus is also a serviceable nerve tonic, and suprarenal extract, somewhat similar in action, is a prompt and energetic agent. As cardiac sedatives, bromide of zinc, valerian and aconite are useful. Aconite is of special service in cases where digitalis and drugs of its class have been used to excess. In the mildly neurotic heart, monobromate of camphor is efficient, and belladonna, both internally and externally, is helpful in mild anginoid attacks and arhythmia. In severe attacks of dyspnea Dr. Satterthwaite has found nitroglycerin the most reliable agent. In fact, he now always uses the nitrites for cyanosis or dyspnea in place of digitalis. They operate in less than two minutes and their effects continue for nearly an hour. In continued dyspnea the inhalation of oxygen gas is of great assistance. For sudden and violent attacks he gives capsules containing nitroglycerin, amyl nitrite, menthol and oleoresin of capsicum, suspended in castor oil. All forms of opiates and other similar drugs are to be avoided, as a rule, but if a hypnotic is absolutely essential paraldehyde or trional is to be preferred. If a patient who is unfortunate enough to have taken these drugs will substitute for them a course of baths and exercises, the result will be a revelation, because it will be found at once that such agents can be dispensed with. Laxatives are essential in the treatment of chronic heart diseases, and they should be carried to the point of producing at least two liquid or semi-liquid movements a day. In arteriosclerosis, the iodides are indispensable, and in the syphilitic form the bichloride of mercury is equally essential. Satisfactory treatment is almost always incomplete without some medication directed to the gastro-intestinal tract, and here is a field for the whole range of digestives and anti-fermentatives. In case of overweight great help is obtained from a strict dietary. As a rule, Dr. Satterthwaite uses digitalis only when special complica-

tions arise. It is chiefly desirable for its diuretic effects, but it is slow, requiring some hours before the physiological action is obtained; so that one cannot depend upon it in an emergency. The more he sees of heart disease, he said, the more he is convinced that digitalis is not only of uncertain composition, but unreliable, and therefore a dangerous remedy, especially so far as its direct action is concerned. It may produce spasms of both heart and vessels. In fatty hearts it is particularly dangerous, and even in urinary suppression, in an attempt to get its diuretic effect, one may cause fatal cardiac contraction. Having referred to strophanthus, convallaria, adonis, caffeine, sparteine and apocynum, he said, in conclusion, that he had tried to make it appear that in modern medicine milder methods are replacing the older ones, and in particular that the idea of absolute rest has been superseded by rest alternating with activity; venesection has been supplanted by restoration of the capillary circulation, mainly by resistant exercises and carbonated baths; hydragogue cathartics are generally replaced by stomachics, mild laxatives, and diuretics, and heart stimulants by general nerve tonics or sedatives; while drugs of the digitalis group are being gradually abandoned except in particular instances.

Endocarditis and its Treatment.—Dr. Leonard Weber spoke on this topic. In the early years of his practice, he said, he believed, as he had been taught, that endocarditis complicating acute febrile affections was almost always followed by chronic valvular disease; but, as his experience extended, he observed that in some of the cases the patients made a complete recovery, the affected valves returning to their normal condition. When he had seen two or three cases of this kind it occurred to him that means might perhaps be found to arrest the progress of endocarditis and assist Nature to effect a cure by the gradual absorption of the inflammatory materials. When a cusp is affected by benign endocarditis complete absorption of the effused materials may occur, but, if necrosis of a part takes place the valve is permanently damaged. So, too, when calcareous deposits result. It is very desirable, therefore, that something should be done for the patient before there occurs such an amount of connective tissue formation that permanent results will almost inevitably follow. How, then, shall Nature be imitated in effecting a cure? In the first place, there should be absolute rest in the recumbent posture for at least three weeks. Secondly, the continued application of ice, day and night, for three weeks or more. Formerly he had employed counterirritation by means of blisters, but for the past ten years had used ice instead. This is best applied in a tin box curved to fit the surface of the chest. The cold is very useful also in allaying pain and restlessness. It diminishes cardiac action and renders drugs to a great extent unnecessary. A small dose of morphine (⅛ or ⅙ grain) is the ideal remedy, when required. As to the use of blisters, Caton claims that their action is not a matter of counterirritation, but that they directly stimulate the trophic nerves of the part. In the third place, in the fourth week small doses of the iodides should be commenced. Sodium iodide is preferable, and from 3 to 7½ grains may be given three times a day, beginning with the smallest dose. He believes that he has seen good results follow this plan of treatment. It is important that the diagnosis of endocarditis should be made as early as possible. The first evidence of its occurrence (from two to five days before there is any murmur) is a change in the clear, sharp ring of the heart sounds, which are noticed to be a little softer and rougher than usual. When this change is detected endocarditis may be diagnosed, and the treatment indicated should be at once entered upon. The mistake is frequently made of discharging a rheumatic-fever patient too soon. By keeping the patient quiet and continuing the use of the salicylates, acute endocarditis may often be prevented.

The Right and Wrong Use of Digitalis Based on Cardiac Pathology.—Dr. Wm. H. Porter read a paper on this subject which will be published in the MEDICAL NEWS.

The Schott Exercises.—Dr. Victor E. Neesen made some remarks on the administration of the Schott exercises, and gave a practical demonstration of the various movements, fourteen in number. He said that since he had been in New York he had seen a great deal of harm done by injudicious attempts to reproduce the Schott treatment. The action of the exercises and baths were very much the same as that of digitalis, diminishing frequency, increasing force, and lengthening the diastole. In cases of arhythmia it is frequently noticed that in one séance the pulse may not stop at all. Among the rules that should be observed in giving the exercises are the following: The movements of the arms should alternate with those of the legs. The patient should be instructed not to hold his breath or strain. No constriction or pressure should be employed by the operator. The movements should be made very slowly, especially at first. In conclusion, Dr. Neesen said it was well to remember the words of Schott—movements without design weaken the heart, while movements with design strengthen the heart.

Exercise before Compensation Fails.—Dr. S. S. Burt said he was a great believer in suitable exercise before the failure of compensation, as it puts the patient in better condition and thus tends to delay such failure. The exercise should be moderate and not competitive, and the patient should always be warned against going to excess in the matter.

The Value of Digitalis.—He said that, while in general not much of a believer in drugs, he certainly would not give up digitalis for any other remedy. If the article used is good and pure and it is given in the right cases, digitalis is of the greatest possible value in ruptured compensations. He employed it always in mitral stenosis. It was of less value in aortic regurgitation, but he did not hesitate to use it there when the heart had given out. Even in aortic obstruction it was sometimes of service. He preferred the tincture and had given up using digitalin, of which he was somewhat afraid. In very edematous conditions digitalis would sometimes fail to act because there was too much pressure. In one such instance he had resorted to tapping the legs, and after a portion of the fluid had been thus evacuated the drug acted so efficiently that the dropsy disappeared entirely. From an extended practical experience he was fully convinced of the very great value of digitalis.

Prophylaxis and Treatment of Endocarditis.—Dr. Egbert Le Fevre said that he was very glad to hear the views expressed by Dr. Weber. He believed that, if cases of rheumatism with threatened endocarditis were treated with the same care as cases of other febrile affections in which severe sequelæ were liable to occur, there would be fewer cases of valvular heart disease than at present. As regards the treatment of endocarditis he had found that in some instances the application of ice did better than counterirritation, and *vice versa*. Sometimes the application of equal parts of chloroform and belladonna over a small surface was very servceable. Out of 34 cases in which he had used colloidal silver, in 22 it had no effect, while in the others it had seemed to cause a marvelous change in the character of the murmur and the heart sounds. In

the iodides and mercurials, for the purpose of causing resolution, as it used to be called, he still had some faith.

Digitalis Has a Legitimate Field.—When given in small doses he believed that digitalis has a legitimate field, and that there could be no question of its value when compensation begins to fail. It should be given preferably at bedtime and in doses of 2 or 3 drops of the tincture. Like Dr. Burt, he even used it in aortic regurgitation. The contraction of the ventricle was a conservative process. Extract of the suprarenal capsule he did not think of benefit.

Digitalis and the Nitrites.—Dr. R. W. Wilcox said that if ten years ago the question had been asked whether digitalis did more good than harm the answer, he thought, would have been doubtful. It is different now, however, because it is given so much in combination with the nitrites. The nitrites are of great service, but are absolutely contra-indicated in old men with rigid arteries and in patients with renal changes. When emergencies rise that call for nitro-glycerin and amyl nitrite, these agents will seldom be found wanting. As to cactus, he said it was the only drug with which he was acquainted that could change a slow pulse into a quick one.

BOOK REVIEWS.

ANESTHETICS AND THEIR ADMINISTRATION. By FREDERICK W. HEWITT, M.A., M.D. Cantab., Anesthetist to His Majesty the King; Anesthetist and Instructor in Anesthetics at the London Hospital. Second Edition. London and New York: Macmillan & Co.

IT has long been customary for writers on anesthesia to deplore the lack of systematic instruction in this branch of practice. The observation of cases and, after a period of such observation, the actual administration of anesthetics form the only satisfactory method of training and instruction, and at present such training, in this country at least, is the exclusive privilege of the hospital interne. Familiarity with Dr. Hewitt's work will furnish the best possible foundation for hospital training in the administration of anesthetics. For those who are thrown into practice without hospital training the book is invaluable, being so constructed as to make available practical hints on the conduct of any case in which doubt exists concerning the anesthetic which should be given in any kind of operation and on any type of patient. The practical value of the first edition is beyond dispute; the present edition has the added merit of formal completeness, owing to the introduction of new chapters on the history, pharmacology and experimental physiology of general surgical anesthesia.

PATHOLOGICAL TECHNIQUE. A Practical Manual for Workers in Pathological Histology and Bacteriology, Including Directions for the Performance of Autopsies and for Clinical Diagnosis by Laboratory Methods. By FRANK BURR MALLORY, A.M., M.D., Assistant Professor of Pathology, Harvard University Medical School, and JAMES HOMER WRIGHT, A.M., M.D., Director of the Clinico-Pathological Laboratory of the Massachusetts General Hospital; Instructor in Pathology, Harvard University Medical School. Second Edition. Philadelphia: W. B. Saunders & Co.

A BOOK designed both as a guide to beginners and as a source of reference to advanced students rarely proves adequate to the demands which it professes to supply. The present volume is an exception to the rule. It is a book which the laboratory worker in pathological histology and bacteriology can use intelligently and profitably from the beginning to the end of his technical course. The three major parts of the work are devoted respectively to postmortem examinations, to bacteriological methods, and to histological methods. In this edition, as in the first, there is no separate discussion of methods of examination of the urine; those points which fall within the province of the pathologist find incidental mention. In the section on bacteriology the authors have amplified the description of the parasite of actinomycosis and have inserted descriptions of the bacillus of bubonic plague, of the parasite of mycetoma (Madura foot), and of Wright's method for the cultivation of anaërobic bacteria. In its present form and place the section on the clinical examination of the blood is practically useless. Such a description of technic, standing alone, can be of no assistance to the clinical worker. As an introduction to a description of the clinical pathology of the blood it would lack completeness, but would occupy a more logical and useful position.

ATLAS AND PRINCIPLES OF BACTERIOLOGY AND TEXT-BOOK OF SPECIAL BACTERIOLOGICAL DIAGNOSIS. By Dr. K. B. LEHMANN and R. O. NEUMANN, M.D., Ph.D. Edited by GEORGE H. WEAVER, M.D. Second Edition. W. B. Saunders & Co., Philadelphia and London.

IN the preparation of this second edition the literature of the past three years has been conscientiously studied. Everything which seems of importance up to about June, 1899, has been taken up. The sections on the morphology, chemical composition and biology and micro-organisms contain all that is to be desired. The statements are clean cut and leave no doubt in the mind of the reader as to the ideas the authors intend to convey. Especially meritorious are the sections on the chemical activity and pathogenic action of bacteria. These important properties are dealt with in a much more competent and exhaustive manner than is usual in works of this kind. A number of the definitions throughout these sections are different from those in ordinary use and are not likely to be accepted, in this country at least, for instance the definitions of the terms asepsis, antisepsis, sterilization and disinfection.

The nomenclature adopted in the classification of bacteria is the same as that employed in the first edition. It is as simple and accurate as the present knowledge will allow and can be warmly commended. In Part II. (Special Bacteriology) descriptions of about eighty species are newly introduced. In this section of the work the text is admirably arranged for ready reference. Of special mention is the exhaustive consideration of the typhoid, diphtheria and tubercle bacilli. The classification of the last two organisms together with the lepra and smegma bacillus under actinomycetes cannot be commended.

A portion of the appendix is devoted to the essentials of bacteriological technic. This section of the work is markedly condensed and will be found convenient for reference by the advanced worker. It is hardly exhaustive enough, however, to be of much use to the beginner. Taken *in toto* the work forms an interesting addition to existing bacteriological literature.

BOOKS RECEIVED.

The MEDICAL NEWS *acknowledges the receipt of the following new publications. Reviews of those possessing special interest for the readers of the* MEDICAL NEWS *will shortly appear.*

PUBLIC HEALTH REPORTS. Vol. XV., Parts I. and II. Government Printing Office, Washington.
